THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

M A S

MASSA'GETÆ, an ancient people of central Asia, in an expedition against whom Cyrus is said to have lost his life. (Herod., i. 201-216; Justin., i. 8.) It is difficult to determine their position; but it appears probable that they dwelt north of the Jaxartes (Sihon), in the country which is at present inhabited by the middle horde of the Kirghis. Herodotus says that they lived north of the Araxes, by which he probably means the Jaxartes (i. 261), and to the east of the Caspian Sea. According to Strabo, the Hyperborei, Sauromatæ, and Arimaspi dwelt above the Euxine, the Ister, and the Adriatic; and the Sacæ and Massagetæ above the Caspian (p. 507, Casaubon); and a little further he remarks that the Massagetæ were to the east of the Dan, who bordered on the Caspian Sea (p. 511).

Herodotus was in doubt whether the Massagetæ ought to be reckoned among the Scythians (i. 201); but they were usually regarded as part of the Scythian nation by succeeding writers. (Arrian, iv. 17; Pliny, *H. N.*, vi. 19.) Herodotus appears to have used the name of Massagetæ to designate all the nomadic tribes of central Asia east of the Caspian; while he confined that of Scythia to the country north of the Euxine and the Danube. The similarity of their name (*Massa-getæ*; compare *Tyri-getæ*, *Thyssa-getæ*) would lead us to suppose that they were connected with the Getæ of Europe.

The Massagetæ are described by Herodotus as a numerous and powerful nomadic people, who resembled the Scythians in their dress and mode of life. Gold and silver were plentiful among them; but no iron nor silver was found in their country. They were however in a very low state of civilization even for a nomadic people. They had a community of wives; and their aged people were killed and eaten by their relations. (Compare Rennell's *Geography of Herodotus*, sect. x.; and as to the custom of eating their parents, the article BATTAS, and Moore's *Notices on the Indian Archipelago*, Singapore, 1837.)

MASSA'RUM, a provisional generic name of Blainville for *Alcyonium Massa* of Müller.

MASSILLIA. [MARSEILLE.]

MASSILLON, JEAN BAPTISTE, was born the 24th of June, 1663, at Hières, in Provence, and at a very early age entered the Collège de l'Oratoire* of that town; but his father, intending him for the profession of a notary, withdrew him before he had completed his studies. Massillon however eagerly seized every opportunity of returning, and his father was ultimately prevailed upon to allow him to re-enter the college, which he did in 1681, and commenced the study of theology under P. de Beaujeu, afterwards bishop of Castres. Here he read the sermons of Lejeune, and, being pleased with them, made some attempts in that species of composition himself, which, although acknowledged to be successful, did not satisfy his own taste. In 1696 he was called to Paris to direct the seminary of St. Magloire, where he composed his first ecclesiastical conferences, which, although

differing in tone from his sermons, were not wanting in vivacity. Although a great admirer of Bourdaloue, Massillon did not take him for his model: he was desirous of opening a new way, and of searching the human heart, its secret passions and interests, in order to arrive at the motives and combat the illusions of self-love by reason and powerful appeals to the feelings. In the pulpit he appeared without gesture or any extravagant display of action; nevertheless when he grew animated, his look and deportment became so expressive, that at this time, when the orators of the pulpit were held in high estimation as patterns of declamation, the celebrated actor Baron, struck with the beauty of Massillon's style, exclaimed, 'There is indeed an orator, but we are merely comedians.' At Versailles he was as successful as he had been at Paris. The court of Louis XIV. was composed of men who might be touched though not convinced. Massillon felt this, and painted the passions with so much truth and such irresistible force, that even those whose vicious tendencies he exposed were constrained to love and admire him.

In 1704 he preached his second Lent sermon at the court, and with so much success that Louis XIV. promised he would hear him every two years; but for some reason unknown, Massillon was never again at Versailles. In 1709 he delivered the funeral oration of the Prince de Conti, which, though much applauded as delivered from the pulpit, was greatly criticised when it appeared in print. After the death of Flechier in 1710, Massillon remained the last of the orators of the *grand siècle*.

In 1717 Massillon was made bishop of Clermont, and preached before the king his last Lent sermon, which is considered to be his *chef-d'œuvre*; and in 1719 was consecrated in the king's presence by Cardinal de Fleury. Massillon abolished in his diocese those indecorous processions that the ages of ignorance had perpetuated, and also certain superstitious customs spoken of in the *Origines de Clermont*. He died on the 18th September, 1742, of apoplexy.

The fame of this celebrated man stands higher than that of any preacher who has preceded or followed him, by the number, variety, and excellence of his productions, and their eloquent and harmonious style. Grace, dignity, and force, and an inexhaustible fecundity of resources, particularly characterise his works. His *Œuvres*, consisting of six volumes, may be justly considered as so many *chef-d'œuvres*. Massillon, in his sermons, endeavoured to convince the young king Louis XV. that he derived his authority from the people, and should never exercise it but for their advantage, nor deceive himself by thinking that he could do no wrong.

The most interesting of his works, next to his sermons, are his 'Conferences,' which are discourses addressed to the young ecclesiastics under his direction in the seminary of St. Magloire.

In a discourse entitled *De l'Ambition des Clercs*, he contends that the Church has a need of great names for its

* This College was established by Cardinal Berulle in the beginning of the seventeenth century.

support, but of exemplary virtues; and that profane manners and worldly inclinations, and not the humble origin of its clergy, are the things calculated to dishonour it. His discourse on the application of ecclesiastical revenues is strikingly prophetic, inasmuch as all the consequences which he foresaw have been verified in a remarkable manner. It is worthy of remark that his sermon 'on the small number of the elect' received the approbation of Voltaire, who observes that preachers in general would do better by repeating such models than by composing original discourses of inferior character. Massillon's works were collected and published by his nephew, in 12 vols. 8vo., in 1745 and 1746.

MASSINGER, PHILIP, born at Salisbury, in the year 1594, was the son of one of the earl of Pembroke's retainers,* who appears to have been employed as a special messenger to Queen Elizabeth. In 1602 he was entered at St. Alban's Hall, Oxford, where he was supported by the earl of Pembroke. Here, as Anthony à Wood informs us, he spent his time in reading 'poetry and romances' rather than 'logic and philosophy, which he ought to have done, as he was patronised to that end.' Perhaps it is unnecessary to fall upon Anthony so harshly as Gifford does for this assertion. The biographer merely means to say that it was a kind of dishonesty to spend the time for which he was indebted to another person in studies alien to those which his benefactor wished him to pursue. Be this as it may, his works are a sufficient contradiction to the accusation of wasted time; and if the earl of Pembroke lost a chaplain, the world has gained what is worth many homilies.

Massinger took no degree, and also seems to have lost his patron's favour. The reason is uncertain, but Gifford supposes that the poet changed his religion at Oxford, and consequently alienated his Protestant friends. Whether he ever did change his religion at all rests on Gifford's inference from certain expressions in his works; but be this as it may, he was driven to betake himself to dramatic composition about the time of his arrival in London. It is probable that he did not for some years attempt anything beyond assisting others in the composition of plays, for we hear little or nothing of him as an author until the appearance of his 'Virgin Martyr' in 1622, sixteen years after his arrival in London. There is evidence moreover to prove that after Beaumont's death in 1615, he assisted Fletcher in the composition of some of the numerous plays (between thirty and forty) which appeared under that author's name during the succeeding ten years. During the rest of his life, Massinger was employed in writing plays, the last of which appeared only six weeks before his death, which took place the 17th of March, 1640, at his own house on the Bankside. His name is noticed in the Burial Register of St. Saviour's with the affecting addition 'a stranger,' showing that the poverty which had pursued him through life had not allowed him resting time enough to make himself known even to the clerk of his own parish.

Massinger's situation as last in order of time of the great dramatic poets of the sixteenth and seventeenth centuries, is probably the reason why he was so utterly lost sight of for seventy years after his death. The first thing we hear of his works is Rowe's intention of editing them, which he afterwards changed into an actual piracy, by which he adapted the 'Fatal Dowry' to suit the taste of the eighteenth century, under the name of the 'Fair Penitent.' That such an audacious forgery could have been palmed on the public and remain undetected for more than half a century is sufficient evidence what easy victims the reading public of those days must have been in the hands of fashionable authors.

In 1759 a bookseller's edition of Massinger appeared, which was followed in 1761 by another; and in 1777 by a third, edited by Monck Mason. On these editions Gifford, the last editor, throws many and apparently well-deserved slurs. Those who wish to see the whole controversy will do well to refer to the *Edinburgh Review* for 1808, where the battles of the earlier editors are fought with considerable prowess.

Gifford gives a complete list of Massinger's plays, with the dates of their appearance, which range from 1621 to 1640. They are thirty-seven in number, including those of which he wrote only a part, but which went under his name. Of these eighteen remain, and ten, if not twelve more, could have been added to their number had it not

* His father's name has occasioned some dispute among the editors. Gifford asserts it to be Arthur, in which he is probably right.

been for the detestable folly of Warburton, through whose carelessness the MSS. were destroyed by a servant.*

There is a peculiar interest in Massinger's plays derived from the state of the times in which they were written, and the bearing and influence which they must have exercised on those national feelings from which, as is probable, they took their own actual shape. No one who reads the play called 'The City Madam' can help seeing in it the exposition of a state of society likely to give birth to troubles, as well as the direct exhibition of many of those opinions and feelings which took such active part in the Revolution then impending. We see there portrayed a city opulent to extravagance, courtiers needy and unprincipled, and a landed proprietor of no family not scrupling to compare himself with one of the barons of the realm, and appearing to advantage as a blunt honest man contrasted with a noble, overbearing and insolent, though not intended by the poet to exhibit any vices except those incident to all members of his order.†

Still more striking are the political doctrines contained in 'The Maid of Honour.' Massinger is, we believe, the only dramatist of his time who did not either openly or in secret espouse the court doctrine of the divine right of kings. A line in one of Camiola's speeches is worth quoting, as it gives what is evidently the poet's view of the subject. She there says to the king of Sicily—

'When you are unjust, the deity
Which you may challenge as a king, parts from you.'

And this is one of the numberless instances in which Massinger evidently conveys his own sentiments on questions then stirring, through the mouths of his characters. In fact, an analysis of the political references in Massinger's plays would be a work of great extent, as they abound in every scene, and at the same time one of no little interest, if it were only for the sake of possessing a commentary on the events and opinions of the day, by a man like Massinger.

Massinger's plays are distinguished by an almost entire abstinence from common oaths, and although we cannot add to this that they contain no coarse or even disgusting passages, we may, in respect to some of them, those for instance in the 'Virgin Martyr,' shift the blame from Massinger himself to his coadjutor in the composition. Whether this abstinence from profanity arose from the restraining influence of the growing prejudice against stage-plays, or from Massinger's own taste, we cannot now tell, but the delicacy, approaching to feminine, so evident in his writings, would induce us to ascribe it to the poet's own choice. On the whole however it is not too much to say that in dramatic power, in delicacy of expression, and in beauty of thought, he approaches more nearly to Shakspeare than any of his contemporaries.

Massinger's extant plays are, 'The Old Law,' 'The Virgin Martyr,' 'The Unnatural Combat,' 'The Duke of Milan,' 'The Bondman,' 'The Renegado,' 'The Parliament of Love,' 'The Roman Actor,' 'The Great Duke of Florence,' 'The Maid of Honour,' 'The Emperor of the East,' 'The Fatal Dowry,' 'A New Way to pay Old Debts,' 'The City Madam,' 'The Guardian,' 'A Very Woman,' and 'The Bashful Lover.' (Gifford's Preface to Massinger; and the *Edinburgh Review* for 1808.)

MASSINISSA. [NUMIDIA.]

MASSOWAH. [ABYSSINIA.]

MASSURA'DA, or **MESURA'DO**, CAPE, is situated on the western coast of Africa, in 6° 20' N. lat. and 10° 30' W. long. It is formed by a hill about 400 feet high, steep on the west and north-west sides, but declining gradually in other directions. It forms the southern extremity of a bay which affords good anchorage in the dry season, but is open to the north-west. Massurada Bay receives the river Massurada or Rio Doro, which runs along the range of hills that terminates in the cape, and would fall into the sea close to the cape if it were not for a spit of land which runs from the latter in a north-north-east direction across the stream and turns it along the shore for about half a mile. At the mouth of the river is built the town of Monrovia, the principal place in the American settlement of Liberia. This settlement was formed in 1821, by the American Coloniza-

* It is scarcely credible, but such is well known to be the fact, that Warburton, a man professing literary taste, actually left fifty-two manuscript plays in a place of common access for years, the consequence of which was that all except three were destroyed.

† The reader who will take the trouble to compare the Introduction to Guisot's 'History of the English Revolution' with this play will find the one an admirable commentary on the other.

tion Society, on nearly the same principles and for the same object as the English settlement at Sierra Leone. The Society acquired by purchase the country along the coast lying between Cape Mount and Trades Town in the kingdom of Sanguin, on the Grain-coast of Guinea, an extent of about 140 miles. Many small rivers water this coast; and though most of them are encumbered by shoals or rapids, boats of moderate size may ascend them for 40 or 60 miles, after which the navigation is usually impeded by cataracts. The country is generally level, and well adapted to the cultivation of Indian corn and rice. The rice raised here is highly prized. Several fruit-trees are indigenous, as the shaddock, and lemons; other fruits have been introduced. The mean annual temperature appears to be between 76° and 78°, and in the dry months (from June to October) the country is frequently visited by tornados or hurricanes from the north-west.

The inhabitants consist of negroes who have obtained their liberty in the United States or are born of free negroes, and such as have been taken from vessels engaged in the slave-trade. According to the laws of the Society, whites are not permitted to settle in this colony, with the exception of the agents of the company, some physicians, and missionaries. The blacks enjoy all the rights of free citizens, as in the United States themselves, and choose their own magistrates, among whom are two censors, who look after the morals of the inhabitants. In 1828 the number of the settlers amounted to 1200, of whom 700 were in Monrovia, but it is said that the number has considerably increased of late. The settlers are more occupied in trading with the neighbouring nations than with agriculture.

(Innes's *Liberia, or the American Colony of Free Negroes on the Coast of Africa*; and *West African Sketches*.)

MASTER OF ARTS. [ARTS.]

MASTERWORT, the old name of an umbelliferous plant with fleshy tuberous roots, growing in moist meadows and woods in the north of Europe and in Newfoundland. It has a stem from one to two feet high, broad twice-ternate leaves, flat large umbels of white or pink flowers, and thin orbicular straw-coloured fruit. Botanists call this plant *Imperatoria Ostruthium*; it has acrid, bitter, somewhat aromatic roots, and formerly had a great reputation as a remedy for toothache, and as a cure for agues, whence no doubt its names have been derived. It retains a place in continental medical practice, but it is disused in England.

MASTICH, a resin which is extracted from the trunk and branches of the *Pistacia lentiscus* by incision. This tree grows in the Levant, and particularly in the island of Chios. The fluid which exudes soon concretes into yellowish-white grains or tears, which are semitransparent, brittle, and have a slight but rather agreeable odour and taste. When thrown on burning coals, mastich gives a more penetrating smell. Its specific gravity is 1.074. It is composed of two resins, one of which is soluble in dilute alcohol, and the other is not; this last constitutes from 1-5th to 1-12th of the whole weight of the mastich, and possesses very nearly the characters of copal, it being soluble in absolute alcohol, ether, and oil of turpentine; these liquids also dissolve mastich without leaving any residue. When the portion which is insoluble in dilute alcohol is reduced to powder, and long exposed to the air, it is rendered soluble by the change which it undergoes.

In foreign Pharmacopœias mastich is employed in several ointments, plasters, and fumigating powders; it is retained in the *Materia Medica* of the London Pharmacopœia, but does not enter into any preparation except as a tincture for preparing what is usually called *eau de luce*. Mastich is principally employed as an ingredient in varnish, and as a temporary stopping for carious teeth.

MASTIFF, the name of a variety of dog of a very old English breed, now seldom seen in its original state of purity. Manwood states that the word is derived from *mase thefese*, because it is supposed to terrify thieves by its voice, which, when the animal is excited, is fearfully deep and loud. This is the *Dogus de forte race* of Buffon and the French, the *Mastivus* of Ray, the *Canis Molossus* of Linnaeus, and the *Villaticus* or *Catenarius* of Dr. Caius.

A true-bred mastiff is of considerable size, and very stoutly built. The head is well developed and large, the lips deep and pendulous on each side of the mouth, and the whole aspect noble.

It appears from Claudius and Grælius that the British dogs, mastiffs probably, were highly prized at Rome; and

Camden notices the employment of a special officer, *Procurator Cynegii*, appointed in Britain for superintending the breed of these dogs and their transmission to that city, where they appeared in the combats of animals at the amphitheatre, and sometimes upon occasions even more cruel, for there can be little doubt that they were set to worry those unhappy Christians whom the tyrants of the time ordered to be sewed up in the skins of beasts and then exposed to the attacks of those powerful and savage dogs. Pennant quotes Strabo for the fact that the Gauls trained British mastiffs for war, and used them in their battles. According to Dr. Caius, three were a match for a bear, and four for a lion; but Stow mentions a lion fight with three of these dogs, in which, though two were disabled, and afterward died, the lion was so much harassed that he retreated, and refused to resume the battle.

The mastiff is capable of great attachment, and when kept as a guard is of unflinching vigilance, giving the alarm by its powerful bark, and never ceasing till it has roused the family or secured the intruder. It is now comparatively little used as a watch-dog, especially in great towns, where an active police has almost entirely superseded it.

Mastiff.

MA'STODON, the name of an extinct genus of gigantic Pachydermatous Proboscidian Mammals (*Mastotherium*, Fischer), whose remains are found abundantly in the third and fourth, or Pliocene, divisions of the tertiary fresh-water deposits, and also, but less frequently, in the deposits of the second or Miocene period.

In the greater portion of their organization the Mastodons must have closely resembled the elephants. The tusks, the proboscis, the general conformation of the body and the limbs, were very similar; and the principal distinction between the two genera was formed by the molar teeth. These indeed were gradually pushed forward from behind as they are in the elephant, and displayed the same relative increase in proportion as the animal was advanced in life; but, unlike those of the elephant, their crowns exhibited on cutting the gum large conical points of a mamiform structure, whence the animal derives its name. As these conical points were worn down by mastication, the tooth presented disks more or less large according to the degree of attrition which it had undergone. The following cuts, which are very much reduced in size, as will be understood from what we have already stated, will explain this difference in the tooth more clearly than words. Before the tooth has suffered from detritus it presents the following appearance:—

Molar tooth of Mastodon, not worn.

And after exposure to a comparatively small degree of detrition it has the aspect represented in the following cut.

Molar tooth of Mastodon, slightly worn.

But when from longer use the conical teat-like points are more deeply worn down, the following appearance is presented.

Molar tooth of Mastodon, a good deal worn, seen from above.

The way in which these teeth are set in the upper jaw will be seen from the following cut.

Molar teeth and palate of Mastodon.

And the mode in which those of the lower jaw are arranged will be perceived from the figures given below.

Portions of lower jaw of Mastodon.

The general contour of the lower jaw as viewed from above may be collected from the following figure.

Portion of lower jaw of Mastodon.

The remains of the *Great Mastodon*, *Mastodon giganteus*, Cuv., appear to have been the first that attracted attention. These occurred in considerable abundance in North America. They gave rise to much speculation and much erroneous opinion, at first; for though the form and size of the molar teeth forbade the inference that they could have belonged to any of the large existing animals, the formidable appearance of the pointed conical tuberosities of the crowns led to conclusions directly the reverse of truth, as we shall presently see. Daubenton, indeed, at first thought that some of these teeth belonged to the Hippopotamus, but he soon perceived that they must have formed part of an animal which had no recent analogue, and Buffon announced that the whole evidence afforded by the remains led to the belief that this ancient species, which ought to be regarded as the first and the largest of terrestrial animals, existed only in the first ages of the world ('n'a subsisté que dans les premiers temps'), and never had come down to our time. This opinion of Buffon did not extend beyond the larger molar teeth, and he still regarded the middling sized and worn teeth as those of the Hippopotamus; he also followed Daubenton in considering the femur found with the teeth as that of an elephant, though Dr. Hunter (William) had pointed out the differences between it and the same bone in the elephant, as well as the distinctions existing in the teeth and lower jaw. (*Phil. Trans.*, vol. lvi.) But while William Hunter did this good service, he introduced no small confusion and error. He had heard of the Siberian *Mammoth*, and not having seen the bones of that animal, he immediately concluded that it was identical with the North American fossil, and gave the name to the latter, a nomenclature which was for some time adhered to both by the Anglo-Americans and the English. The skeleton of the Great Mastodon was exhibited at London and Bristol as the *Mammoth*, and accounts of it under the same name were published in London in 1802 and 1803. Nor was this the only error of which William Hunter was the parent, for notwithstanding the rejection of such an opinion by Camper, the former declared that, from the structure of the teeth, the *Mammoth*, as he termed it, was carnivorous; and men, ever prone to catch at the wild and wonderful, greedily adopted this marvellous view, and named the gigantic beast the *Carnivorous Elephant*. We well remember in our early youth hearing the speculations of some us to the sort of prey on which the monster lived, and as to the great services that its enormous tusks, which in the skeleton above noticed were placed in an inverted position, with the curvature downwards, must have rendered when the animal was on its predatory excursions. The confusion created by the application of the same name *Mammoth* to two different genera was great, and for a long time almost inextricable, notwithstanding the endeavours of Pallas, who clearly refuted the supposed identity of the Siberian and American animals, by showing that the Siberian *Mammoth* is a true elephant. Cuvier at once dissipated the clouds that had gathered over the subject, and while he clearly pointed out the osteological differences between the two genera, gave to the supposed *Mammoth* of America the appropriate name of *Mastodon* (*Μαστός*, a teat; *ὀδός*, a tooth).

The first notice of the teeth and bones of this extinct genus of pachyderms appears to be in '*Phil. Trans.*' (vol. xxix., 1714), a century and a quarter ago; and it is not uninteresting to observe what rapid strides natural science has made since that time, when the Royal Society of London published in their Transactions Dr. Mather's letter to Dr. Woodward, in which the former gives an account of a large work in MS. in two vols. folio, but does not name the author. Dr. Mather recommends this

work, which appears to have been a commentary on the Bible, with large philosophical remarks, to the patronage of some generous Mecenas, to promote the publication of it, and transcribes, as a specimen, a passage announcing the discovery, in 1705, of enormous bones and teeth at Albany in New England, as the bones of a giant, appealing to them as a confirmation of the text in *Genesis* (vi. 4); another example, if any were wanting, of the folly and danger of mixing up religious questions with scientific inquiries. Portions of remains were sent to France and England at different intervals, and elicited the observations of European zoologists, whilst in America materials were collected for forming two complete skeletons by the zealous industry of Mr. Peale.

Of these two skeletons one was placed in the museum of Mr. Charles Wilson Peale in Philadelphia, and the other was exhibited in London and Bristol by his son Mr. Rembrandt Peale, who published two accounts of it under the name of the *Mammoth* above alluded to.

One of the principal deposits of Mastodon bones appears to have been the Big-bone Lick in the north part of Kentucky, near the Ohio, whence the Mastodon has been called 'the animal of the Ohio.' None of the remains have the appearance of having been rolled, but seem to have been unmoved since the death of the animal; and it is worthy of remark that those which were found at the river of the Great Osages, which runs into the Missouri a little above its confluence with the Mississippi, were in a vertical position, as if the animals had been bogged or buried in the mud. [MEGATHERIIDÆ.]

The traditions which were rife among the Red Men concerning this gigantic form and its destruction must not be passed over in silence. M. Fabri, a French officer, informed Buffon that the savages regarded these bones scattered in various parts of Canada and Louisiana as belonging to an animal which they named the *Père aux loups*. The Shawnee Indians believed that with these enormous animals there existed men of proportionate development, and that the Great Being destroyed both with thunderbolts. Those of Virginia state that as a troop of these terrible quadrupeds were destroying the deer, the bisons, and the other animals created for the use of the Indians, the Great Man slew them all with his thunder, except the Big Bull, who, nothing daunted, presented his enormous

forehead to the bolts, and shook them off as they fell, till, being at last wounded in the side, he fled towards the great lakes, where he is to this day.

Buffon seems to have been the first who noticed the occurrence of these teeth in the Old World, and figures one alleged to have been found in Little Tartary, and given to him by the Comte de Vergennes. This is very large, having from eight to ten points and weighing eleven pounds four ounces. He also figures another from the museum of the Abbé Chappe, said to have been brought from Siberia. Pallas announces another instance; and gives a figure of one from the Oural Mountains. Cuvier states that he for a long time thought that his *Mastodon giganteus* inhabited the Old Continent as well as America, but he confesses his doubts as to this point. The Abbé Chappe, he remarks, had been in California, and there is no certain evidence that he brought back his Mastodon tooth from Siberia. The tooth figured by Pallas, he thinks, may perhaps have belonged to *Mastodon angustidens*, and he asks, who shall assure us that the Comte de Vergennes was not in error as to the locality of the great molar presented by him to Buffon, and which, together with that formerly in the cabinet of the Abbé Chappe, is in the Paris Museum? Cuvier sums up by saying that he does not entirely pretend to invalidate these three proofs, but that he begins no longer to regard them as sufficient.

The following species have been named: *Mastodon giganteum*,* *M. angustidens* (Europe, America?), *M. Audium* (Andes), *M. Humboldtii* (Concepcion—Chili), *M. minutus*, *M. Tajiroides*, *M. Turicensis*, *M. Avernensis* (Epplesheim, Puy de Dôme), *M. elephantoides* (Irawaddi, Sewalik Mountains), *M. latidens* (Irawaddi, Sewalik Mountains), and *M. longirostris*, Kaup. Professor Owen has referred the teeth from the Norfolk crag to the last-named species.

Example, *Mastodon giganteus* (Cuv.)—Syn., *Mastodon maximus* (Cuv.), *Mammot Ohioticus* (Blum.), *Harpagmothierium Canadense* (Fisch.), *Elephas carnivorus* (Gul. Hunter), *Mammoth* of William Hunter and of the Anglo-Americans.

Young.—*Tetracaulodon*. (Godm.).

Localities.—The United States. Europe?

This species must have equalled the Elephant in height, but seems to have been longer and stouter in its proportions.

Skeleton of *Mastodon giganteus*.

Remains of *Mastodon* were found by Capt. Cautley in the Sewalik Mountains; and in assigning an age to the formation, the Captain adopts the views of Dr. Falconer, who considers the deposit to be synchronous with that from which Mr. Crinford obtained the remains near Promo, on the banks of the Irawaddi. Captain Cautley having found jaws in which the front teeth are not to be distinguished from the teeth of *M. latidens*, and those in the rear from the teeth of *M. elephantoides*, he concludes that the dis-

tinction which was established on detached teeth will be found to be erroneous.

The genus *Tetracaulodon* of Godmann is, according to the best authorities, the young of the Great *Mastodon*—*Mastodon giganteus*. One species only, *Tetracaulodon Mastodontoides* (Godm.), is recorded. (Harlan, *Bull. des Sc. Nat. et de Géol.*, 1830.)

MASTODONSAURUS, Dr. Jäger's name for an extinct *Giganteus* properly.

found in the *alaunschiefer*, or alum slate, (Würtemberg), founded upon teeth, the largest of which, with part of the stone adhering, is figured below, one-half of the size of the original. The other teeth were considerably smaller.

Dr. Jäger is of opinion that these teeth must be held to approach the nearest to those of the animals belonging to some of the species of *Monitor*. The *Mastodonsaurus*, from the length of its teeth, may be said, in his opinion, to have equalled the *Mosasaurus* of Maastricht in size; but in the formation of the teeth the former differs from the latter. The small teeth, he observes, agree so much in every respect with the large one, that their difference in size is only to be ascribed to their having belonged to animals of a different age, but not of a different genus, and also to their having occupied different places in the jaw.

Tooth of *Mastodonsaurus*.

(Dr. Jäger's memoir, *Über die Fossile Reptilien welche in Würtemberg aufgefunden worden sind*, Stuttgart, 1828.)

MASULIPATAM, a district of the province known as the Northern Circars in Hindustan. It is bounded on the north by Rajamundry, on the east by the Bay of Bengal, on the south by Guntoor, and on the west by the dominions of the Nizam. The district which now goes under the name of Masulipatam comprises three of the five original Northern Circars, viz. Condapilly, Ellore, and Masulipatam, and forms a collectorate under the English government. The population amounted, in 1822, to 454,754, and the public revenue to about 150,000*l*. This district contains a large proportion of uncultivated grass-lands, and towards the north there is a great deal of jungle. The principal produce is grain, and some cotton of good quality is raised.

MASULIPATAM, the capital of the district, is a seaport of some consequence, in 16° 10' N. lat. and 81° 14' E. long. About a mile and a half south-east from the town is a fort in the form of a parallelogram, 800 yards long by 600 yards broad: there is a straight causeway between the fort and the town upwards of 2000 yards long. There is a considerable manufacture of chintzes in the town and neighbourhood, great quantities of which are exported: they are much esteemed in the greater part of Persia. This is almost the only part of that line of coast on which the surf does not beat; it affords good anchorage for ships of 300 tons burthen. The French established a factory at this place in 1750. It was taken by assault in 1759, by the English under Colonel Forde, and has since continued in our possession. Masulipatam is 203 miles from Hyderabad, 292 miles from Madras, 764 from Calcutta, and 1084 from Delhi, all travelling distances.

MATABUNGA. [HINDUSTAN.]

MATAGORDA. [MEXICO.]

MATAPAN, CAPE. [LACONICA.]

MATARO', a seaport of Cataluña in Spain, in 41° 33' N. lat. and 2° 30' E. long. It is said to have been founded by the Romans, and to be identical with the Iluro of Ptolemy and Pliny, but the Roman city was farther inland than

the existing town of Mataró, which was founded and named by the Arabs.

The more antient or Moslem part of Mataró stands on a rising ground at some distance from the sea; it is small and enclosed with walls; the streets are narrow and gloomy, with the exception of one called La Riera, which is broad, straight, and handsome, and intersects the town. The modern part of Mataró is of much greater extent, and stretches eastward down to the sea. It is laid out in streets, long, broad, and regular; the houses are neat, and many have their façades painted in fresco as is common in Spain and Portugal. One parish church, five convents (now unoccupied), and an hospital, are the principal public buildings. The population at the commencement of the present century was about 25,000, and was increasing rapidly, but must now be estimated much lower. The manufactures and commerce of Mataró at the same time, owing to the industrious and enterprising spirit of the inhabitants, were in a most flourishing condition, but the loss of the American colonies, to which this town used to export calicoes, laces, velvets and other manufactures in silk, gave the death-blow to its prosperity.

The scenery in the neighbourhood of Mataró is exceedingly picturesque. Inland from the town extends a small but most fertile and cultivated plain, the farms in which, says Townsend, are so many gardens, watered by artificial means, 'and producing on the same spot of ground corn, wine, oranges, and olives.' Bounding the plain are ranges of mountains, whose slopes are luxuriantly clothed with wood. The red wine grown in the plain of Mataró is esteemed the best in Cataluña.

(Laborde, *Itinéraire Descriptif de l'Espagne*; Townsend's *Journey through Spain*; Inglis's *Spain in 1830*.)

MATE'. [PARAGUAY TEA.]

MATERIA MEDICA is that branch of medical science which treats of the articles employed in the practice of medicine, and embraces an explanation of the nature and modes of action of those substances which are had recourse to in order to restore the healthy state of the human frame when its functions or structure are impaired by disease. Thus defined it comprehends both pharmacology and therapeutics. The former means an account of drugs, simple or prepared, in reference to their physical character, natural history, commercial history, chemical composition, and modes of exhibition. The latter means an exposition of the principles which should regulate their employment. The pharmacological part of the subject is sufficiently treated of under each article, as it presents itself in alphabetical order, and it is only requisite to treat here of the general principles involved in their practical application. For the full and satisfactory comprehension of this department, a previous knowledge of the structure of the body, or anatomy, and, above all, of general anatomy, and of the respective duties or offices performed by its component organs while in a state of integrity, or physiology, and of the various degrees of departure from these, when from any cause they become deranged in their action, or pathology, and the signs by which the morbid states are indicated, or nosology, is required. These departments of science are studied only by those persons who intend to follow the medical profession, and at their hands only can a skilful employment of medicines be expected. Something however may be done for the advantage of the public by pointing out how medicines act, and in what way they prove remedial. The object of the administration of a medicine is to arrest the progress of diseased action, and to remove the consequences of its existence, that is, to restore the individual to perfect health, such as he enjoyed before the organ or organs received the impression of the morbid cause; or where both or either of these objects cannot be accomplished, so to retard the career of the unhealthy operations, as to prolong life to the latest possible period. To improve and perfect this most important branch of the healing art is the end and aim of all the other branches of medical science. The means of accomplishing this object have varied in the different stages of human civilisation, and according as different theories of the nature or cause of diseases have prevailed. Many of the medicines formerly in use were of a disgusting or repulsive nature, or of a kind devoid of any active principle, and therefore inert. Many also owed their introduction into practice to superstition, credulity, or a misapplication of the principles of natural and chemical philosophy, and have long been discarded by scientific prac-

tioners, though frequently retained, by the populace or by quacks. The medicines used in the present day are still drawn from all the three kingdoms of nature, though the animal kingdom yields few, the vegetable kingdom a considerable number, and the mineral kingdom the greatest number and the most active.

In general few articles produce much effect on the human frame, either in a state of health or disease, which are not possessed of marked sensible qualities, impressing the senses of smell or taste in a distinct manner. Hence bland insipid articles are mostly better fitted to furnish nourishment than medicines, being completely digested, and creating no disturbance or change of action of the vital powers of the system; medicinal substances on the contrary do not appear to be thoroughly digested, but a portion remaining unassimilated acts in some measure as a foreign body, and produces a stimulant or alterant effect on the vital power. Many medicines are indeed absolutely poisonous if given in large doses, or where no diseased state of the system requires their administration. For disease often gives to the system a power of sustaining the action of a dose of medicine which would produce serious disorder if given to a person in health; the morbid state of the system seeming to act as an antidote to the medicine, while the medicine acts as an antidote to the disease—health being the result of their neutralizing power.

Medicines produce two distinct effects: one termed the primary, or in some cases, as when given to a healthy person, the physiological effect; the other secondary, or curative, which can only take place when there exists a disease to be removed. The former is generally uniform or constant; the latter too often variable and uncertain. To lessen the degree of uncertainty in the latter and most important of the two kinds of action, many zealous medical men have instituted experiments with different medicines on themselves or others; while chemists have carefully investigated the chemical composition of the articles, and sought to discover their active principles, or to explain their modes of action. Notwithstanding these valuable aids, therapeutics is still the most imperfect of all the departments of medical science, partly from the difficulties inherent in the subject, and partly from inability in medical men to weigh correctly the evidence respecting the effects of medicines. The union of several articles in one prescription, by which we attempt by one stroke to remove several symptoms, tends still further to obscure the results, and to vitiate the conclusions which may be drawn. The polypharmacy of the ancients has been in a great measure abandoned, but still it must be confessed that simplicity in prescribing is not sufficiently studied. (Holland's *Medical Notes and Reflexions on Medical Evidence*, and on *Methods of Prescription*.) On the opposite hand, the attempts to isolate the supposed active principle of many vegetable remedies, and to administer it apart from the others, though in some instances advantageous, by diminishing the size of the dose, or concealing the unpleasantness of the taste, have not produced the consequences expected; for example, in most cases *cinchona bark* administered in some of the old preparations will be found a more valuable tonic than *quinine*. The superiority of many mineral waters, which contain a variety of ingredients in a state of extreme dilution, over the exhibition of the saline materials in a less quantity of liquid, seems to militate against the practice of excessive concentration.

The introduction of new substances into the *Materia Medica*, by the discovery of new plants, or by the progress of chemistry, may supply deficiencies in the catalogue of remedies. But less benefit to mankind will flow from a multiplication of remedies, than from the establishment of clear and scientific rules for their administration. Every improvement in anatomy and physiology will promote the advancement of therapeutics, by leading to greater precision in the employment of medicines. For nothing is more certain than that medicinal substances act upon special parts of the body, in preference to others, and in many instances on those which are diseased rather than on those which are sound. The careful investigation of the modes of action of medicines is worthy of the best faculties and energies of medical men, and every contribution to this department of science should be regarded as an incalculable benefit conferred on mankind.

(Pereira's *Elements of Materia Medica*; and Vogt, *Lehrbuch der Pharmakodynamik*.)

MATERIALISM is a name applied to any philosophical

system which denies the existence of a spiritual or immaterial principle in man, called the mind or soul, distinct from matter, or which (changing the phrase) denies the immateriality of the soul. The name is applied to systems which differ very widely from one another, in respect of the consequences deduced from the denial of the soul's immateriality: and thus it comes to pass that the popular meaning of the word has become loose and incorrect, comprehending what are no better than accidental consequences of the pure and proper idea. Such accidental consequences are the denial of a future state and absolute atheism; and it need not be said that atheism and materialism are treated in current conversation as convertible expressions.

The name materialism also is one of that sort for which Mr. Bentham has constructed the epithet *dyslogistic*. As applied in current conversation, it always carries with it censure. This arises, of course, from the nature of the accidental consequences which have been indicated, and which mankind regard with horror: but inasmuch as the name still continues to be applied to systems from which unchristian and atheistical consequences are expressly excluded, and even to some systems (such as that of Hartley) which admit the existence of a separate soul, but in whose method of explaining mental phenomena there is a dash of materialism, the censure that has come to be indissolubly associated with the name often falls with grievous injustice. Indeed there is hardly a single word in the whole range of philosophic terminology better fitted to exemplify the evils of looseness of application, or of allowing feelings to tinge and discolour the notions conveyed by names.

The systems to which the name materialism is applied may be roughly distributed under a threefold division. First, it is applied (as has been already said) to a system like that of Hartley, which admits the existence of a soul, but which, attempting to explain mental phenomena physically or by movements arising out of the bodily organization, seems to imply materialism. Secondly, it is applied to the systems of Hobbes and Priestley, and of the French school of writers, of which De la Mettrie may be taken as a specimen, which distinctly deny the existence of a soul as a separate principle in man, but which do not deny either a God or a future state. In the systems of these writers is evolved the pure and proper idea of materialism, divested of all unnecessary consequences. Thirdly and lastly, the name is applied to systems like that of the ancient Epicureans, or of Spinoza, which deny both a future state of rewards and punishments and a Divine Creator, systems for which atheism would be the better name, inasmuch as materialism fails to denote their more important and distinctive ingredients.

The following is a brief summary of the views of Dr. Priestley, who has more formally than any other writer enunciated the principles of materialism in the pure and proper sense of the word. He denies the existence of a separate immaterial principle in man, called the mind or soul, because he thinks that an immaterial principle could not exist in union with the material body, and because he thinks further that all mental phenomena (as they are called) may be explained by means of supposed movements arising out of the bodily organization. The method by which he thus explains mental phenomena is that of Hartley. [HARTLEY.] Adopting this philosopher's hypothesis of medullary vibrations, he defines mental phenomena as medullary vibrations perceived; and he contends, principally from the analogy of brutes, that bodily organization is adequate to produce perception. Thus, and by means of such hypothesis, does he dispense with the hypothesis of a separate immaterial soul. But denying the existence of a soul, separate from the body, and capable of surviving when the body perishes, he does not yet deny the immortality of man, and a future state of rewards and punishments. On the contrary, he distinctly affirms these on the authority of Scripture. It is needless to add that Dr. Priestley does not deny the existence of a God. [PRIESTLEY.]

One word more on the absurdity of coupling the denial of a future state with the denial of an immaterial soul, and of making atheism synonymous with materialism. To deny a material soul is necessarily to deny an immortal soul, but not therefore to deny an immortal man. And even to deny the existence of everything save matter in the universe, is not necessarily to deny a Divine principle, as is shown by many of the ancient schools of philosophy [ELEATIC PHILOSOPHY], nor even to deny a moral Governor, as is shown by the philosophy of Hobbes, who, denying in one part of

his writings the existence of all spirit, and in this respect carrying his views further than Dr. Priestley, yet makes God the corner-stone of moral and political science. [Hobbes.] Hobbes distinctly says that there being nothing, in his opinion, but matter in the universe, it follows that God is matter.

But it is to be remarked in opposition to materialism, even as it is put forth by Dr. Priestley, that it is devoid of philosophical foundation, and rests on a disregard of the limits of true philosophy. Its truth cannot be tested by observation. It rests altogether on hypothesis and conjecture. When we go beyond what are called the qualities of the mind, or of matter either, and speculate upon what it is itself, whether it is something else, or different from that something, whether it has or has not an existence, we have no help but in supposing and conjecturing and imagining. Such speculations may doubtless be interesting, and they may have their use too as an exercise for the imagination, but we cannot calculate upon their results. Much mischief is done moreover by mixing up these results with the results of observation, by jumbling together conjecture and philosophy. The true philosopher, not despising, but setting aside as irrelevant to his object, all speculations on the origin and nature of mind, or of matter either, will start from these as first principles, and will apply himself to observing their qualities and capabilities and laws: and the results will be sound psychology and sound physics.

The converse of the word materialism is immaterialism. This is used only as an abstract term, and even thus very seldom; spiritualism being generally used in its place.

MATERIALS, STRENGTH OF. The strength of any material object, as a rod, bar, beam, chain, or rope, is that power by which the substance resists an effort to destroy the cohesion of its parts. It evidently depends on the disposition of the particles relatively to each other, on the intensity of the force by which the particles cohere together, and on the manner in which the straining power is applied. The inquiry into the laws by which the materials employed in the construction of edifices or machines resist the strains to which they are subject is of considerable importance, because upon a just adaptation of the strength at any one point to the strain there experienced (and an excess or deficiency of the former is nearly equally injurious) depends the stability of the whole.

Whatever be the constitution of a rod or beam, the relation between its strength and the strain to which it may be exposed can be made the subject of mathematical investigation only by imagining the material to consist of an infinite number of particles arranged in lines (like fibres or threads) parallel to each other in the direction of its length. The particles in each line must be supposed to cohere together by powers exerted in that direction; and the several lines to cohere laterally with forces which may, or may not, be equal to those exerted longitudinally. In homogeneous bodies, as glass and some of the metals, the particles may be supposed to be symmetrically disposed throughout the masses, and to attract each other in every direction with equal powers: but the case is different in other bodies, particularly in timber; for in such the lateral cohesions of the fibres are much less powerful than the longitudinal cohesions of the particles in each fibre. In ropes the fibres have no lateral cohesion, and the strength depends on the twisting of the fibres together; in consequence of this, as the latter can scarcely be separated from each other in the direction of the length of the rope, the cohesion of nearly all the particles in any transverse section must be destroyed before a disruption can take place.

A rod of any material, consisting of parallel fibres as above supposed, being placed in a vertical position, and strained by a weight applied at the lower extremity, the particles in every fibre will be separated from each other by the action of the weight, and consequently its length will be increased. The cohesive power by which the particles are kept together will, in most cases, be diminished by the separation; and if the weight be sufficiently great, or if it be allowed to act during a sufficient length of time, the cohesive power will be certainly overcome; that is, the rod will, in some parts of its length, be torn asunder. But before this occurs, since all bodies possess a certain degree of elasticity, on removing the weight the attraction of cohesion will cause the separated particles to return towards their original positions; or the rod will become nearly of the same length as at first. That it does not exactly become

so, in general, arises from the imperfect elasticity of the material, on which account the particles come to a state of rest at augmented distances from each other. The elongation of the rod when strained by a weight, and the amount of the weight necessary to produce fracture, will depend on the nature of the material; and, from a want of uniformity in the constitution of materials even of the same kind, though the rods be of like dimensions, great irregularities are found to exist in their power of resisting direct strains. Numerous experiments performed on each of the different kinds of material can alone afford a mean value on which reliance may be placed when it is required to determine the capability of a bar or beam to resist the strain arising from the action of any given force.

If the materials were perfectly elastic, so that the length of the rod became the same, after the removal of the suspended weight, as before that weight was applied, the force of cohesion would evidently be proportional to the intensity of the straining power; and this is generally adopted as an hypothesis in investigations concerning the equilibrium between strengths and strains; it being understood that the latter have only that moderate degree of intensity, compared with the former, which is consistent with the permanent stability of the edifice or machine. The law just mentioned appears to have been discovered by Dr. Hooke; and, as the separation of the particles in any fibre is proportional to the straining power, it follows that, within certain limits, the cohesive power between two particles of an elastic body is proportional to the distances to which one of them is removed by the straining force from the place where it was before at rest. The same law is considered to hold good when the particles of an elastic body are made to approach each other by the action of a compressing force like that of a weight on the top of a vertical pillar.

The power by which the particles in any body resist the action of a force tending to separate those particles in the direction of the length of the body may be considered as constituting the direct or absolute strength; and it is evident that, if the body were of a homogeneous texture, that strength would be proportional to the number of particles in a transverse section; that is, to the area of such section, while the strain is proportional to the weight applied. Therefore, if F designate the cohesive power in a unit of such area, as a square inch, a square foot, &c.; also if A represent the area and W the weight applied, including that of the body itself, we should have $F.A = W$ when the strength and strain are in equilibrio. This formula for the absolute strength may be considered as nearly correct with respect to most of the bodies in nature: and hence (F being determined by experiment) the strength by which a rod of any material resists this kind of strain may be found when the dimensions of the rod are given.

For complete details concerning the experimented values of F , the reader must be referred to the extensive tables which have been published by Barlow (*Essay on the Strength of Timber*); Rennie (*Phil. Trans.* 1818); Tredgold (*Principles of Carpentry*); and Hodgkinson (*Manchester Memoirs*, vol. iv.), our limits permitting us to introduce only the few determinations which follow.

The area of a transverse section of each rod is one square inch, and the values of F are expressed by the breaking weights in pounds avoirdupois.

English oak	$F = 8,000$ to $12,000$
Fir	11,000 to 13,488
Beech	11,500
Mahogany	8,000
Teak	15,000
Cast-steel	134,256
Iron-wire	93,964
Swedish bar-iron	72,064
Cast-iron	18,656 to 19,488
Wrought-copper	33,792
Platinum wire	52,987
Silver do.	38,257
Gold do.	30,888
Zinc do.	22,551
Tin do.	7,129
Lead do.	3,116
Rope (1 inch circumf.) bore	1,000 lb., $F = 12,506$
Whale-line spun by hand	
(2 in. circumf.)	2,240 " 7,037
Do. by machinery (1 1/2 in. circumf.)	3,520 " 12,582

Rope (3 in. circumf.)	5,628 lbs.,	F = 7,858
Do. (4 in. circumf.)	9,988	" 7,845
Cable (14½ in. circumf.)	89,600	" 5,355
Do. (23 in. circumf.)	255,360	" 6,066

Notwithstanding the irregularities in the column concerning the values of F for ropes, it may be concluded that ropes of a given diameter have less strength on each square inch of their transverse section than those of less diameter; and this is owing, no doubt, to their threads being less twisted together. It may be observed also that those woods whose fibres are nearly straight bear much greater weights suspended from them than those whose fibres have considerable curvature.

According to the experiments of Mr. Barlow it appears that a bar of malleable iron is extended one ten-thousandth part of its length by a direct strain equal to one ton for each square inch in the area of the transverse section: when stretched with ten tons per inch its elasticity was injured, or the bar did not return to its original state.

If the fibres in any material body were exactly rectilinear, so that, a rod being placed on one end in a vertical position, no one of the particles were opposite to the intervals between any two in a transverse section below it, it might be conceived that no force compressing the rod in the direction of its length would produce any other effect than that of diminishing its length. But, as we find that all bodies when so compressed may be bent, and finally broken, such a disposition of the particles is destitute of probability. In fact, when a pillar is compressed by a great weight above it, either the fibres, already curved, have their curvature increased, so that the whole pillar bends; or the particles in some of the transverse sections are forced outwards by lateral pressures arising from those above and below their intervals being thrust between them, and then the pillar swells on its whole periphery. The consequence in either case is, that the cohesion of the longitudinal fibres is impaired or destroyed, and the pillar is at length broken or crushed.

The strength of a pillar when so compressed must evidently depend upon the number of particles in a transverse section; that is, upon the area of such section: but since, besides the displacement of those particles from the longitudinal pressure, their lateral cohesion must be overcome before they can be thrust outwards, it is evident that the strength is not proportional to the area, simply, but to some function of that area. No law on which any dependence can be placed has yet been discovered for the strength of a pillar in such circumstances. Euler, from analytical considerations, concluded that it varies as the square of the area; but late engineers have supposed that the square root of the third power of the area more correctly represents the law of the strength.

The following table of the strength by which materials resist this kind of force, when just crushed by the pressure, is extracted from the account of experiments made by Sir John Rennie, but the weights found from the experiments are here reduced, agreeably to the law last mentioned above, to those which might have crushed the materials, if the latter had been formed into prisms having the area of the transverse section equal to one square inch:—

If a bar or pillar, resting on one end in a vertical position, and considered as a perfectly elastic body, be compressed by a weight acting vertically above it, the purely mathematical theory gives the following equation for the value of the compressing weight when the pillar begins to bend:—

$$W = \frac{\pi^3 a d^3}{12 l^2} \delta \quad (\text{Poisson, } \textit{Mécanique}, \text{ tom. i., No. 313});$$

where W = the compressing weight; l = the length of the pillar; a = the area of the transverse section; d = the thickness perpendicularly to the bending surface; δ = the element of deflection; and $\pi = 3.1416$. It follows that, when in two bars of like material a and d are respectively equal, the

P. C., No. 913.

weights which those bars will sustain without bending are inversely proportional to the squares of the lengths.

It is also found, if w be a weight applied as above, and producing a flexure p , measured at the middle of the bar

perpendicularly to its length, that $\delta = \frac{4 w l^3}{a d^3 p}$: this being substituted in the expression for W , the latter becomes

$$W = \frac{\pi w l}{3 p}. \quad (\textit{Ibid.}, \text{ No. 314.})$$

The most important inquiry concerning the strength of materials is that which relates to a beam or bar supported at its extremities on two props, and strained transversely by a weight acting perpendicularly to its length at a given point between the props.

In order to simplify the investigation, it is usual to imagine that the beam, its breadth and depth being supposed uniform, is made to rest on one prop at the place where the weight may have been applied in the former case, suppose in the middle of its length, and that from the points where the two props were situated weights are suspended equal to the reactions of those props in consequence of the first weight; that is, to half the whole weight in the middle. Then, supposing the deflection of the beam to be very small, so that, in the former case, the beam did not slide on its points of support, the effect of the two weights to break the beam on its single prop will be the same as that of the one weight applied as at first supposed. Again, if a beam of equal dimensions with respect to breadth and depth were fixed at one end horizontally in a wall, the part projecting from the face of the wall being equal in length to half that of the former beam; and if a weight were applied at the opposite end equal to each of the two weights applied to the beam on one prop, the effect of this weight to break the beam at the face of the wall will be equal to that of the two weights to break the beam on the one prop, or of the double weight to break the same beam on two props. The investigation for the case at first supposed is therefore reduced to that of finding the strength of a beam attached at one end to a wall, and strained by a weight at the opposite extremity.

Let AB (fig. 1) be the face of a wall, and let MN represent a vertical section of the beam in the direction of its length. Let it be supposed that the beam consists of an infinite number of fibres parallel to MP; then, if these fibres were supposed to be rigid and incompressible, the effect of a weight at P would be to bring the beam to an inclined position, as mn, producing a fracture on the line MQ by drawing the particles on that line away from those which were at first nearly in contact with them. But from experiment it is found that, when a beam is so strained, while the upper fibres are in a state of tension, the lower ones are in a state of compression; and consequently that there is a certain point O in the depth of the beam at which neither of these effects takes place. A line passing through this point perpendicularly to the plane MN is therefore called the neutral axis of the beam, and the termination of the fracture may be supposed to be at O instead of Q; the fibres below the former point having no effect in resisting the tendency of those above to be broken, yet constituting part of the strength of the beam by the power with which they resist compression, and thus oppose the tendency of the beam to turn about the neutral axis. The position of this neutral axis is uncertain; but Mr. Barlow, from experiment, has found that in rectangular beams of wood (the faces being in vertical and horizontal positions) its distance from the upper surface at M bears to the whole depth MQ the ratio of 1 to $1 + \sqrt{3}$, or nearly that of 4 to 11. Therefore, d representing the depth MQ, let OM be represented by $\frac{4}{11} d$.

Now adopting the hypothesis of Leibnitz, which is founded

on the elasticity of the fibres, that the force of cohesion in any one fibre is proportional to the tension to which it is subject, or to the distance of that fibre from the axis about which the beam turns in consequence of the strain; that is, from the neutral axis just mentioned: if x be the distance of any fibre above O from the latter place, and f represent the force of cohesion in the fibre at MP , we shall have $\frac{4}{11}d : f :: x : f \frac{11}{4d}x$: and the last term will express the force of cohesion between two particles at a distance above O equal to x . Consequently, dx expressing the indefinitely small depth of a fibre, we have $f \frac{11}{4d}x dx$ for the cohesive power of a fibre at the same place. But this power acting at a distance from O equal to x , we have $f \frac{11}{4d}x^2 dx$ for the momentum of that force, and its integral will express the strength of all the fibres in the vertical section represented by MN . The transverse section of the beam being supposed to be rectangular, the breadth will be constant; let it be represented by b : then the integral of $f \frac{11b}{4d}x^2 dx$ (between $x=0$, $x=\frac{4}{11}d$), that is $\frac{16b}{363d}f d^3$, or nearly $\frac{1}{23}bd^2f$, will express the strength by which all the fibres above the axis at O resist the strain.

A corresponding expression for the strength arising from the resistance of the fibres below the neutral axis to the force of compression would be the integral of $f' \frac{11b}{4d}x^2 dx$ (between $x=0$, $x=\frac{7}{11}d$), that is, nearly $\frac{2}{15}bd^2f'$ (f' being the force by which a fibre at QN would resist compression), and the sum of the two integrals will be the whole strength of the beam to resist a transverse strain. Now the ratio of f to f' is different in different materials; and if we take $f' = \frac{1}{2}f$ (which is the case in some kinds of wood), the said sum will be $= \frac{1}{9}fbd^2$ nearly.

But when the beam is strained by a weight W applied at P , so that it take the inclined position mn , if we join O and p , and let fall the perpendicular pR on AB , we shall have $W.pR$, or (if l be the length of the beam) $W.l \cos \angle O p R$, for the momentum of the weight. Then $W.l \cos \angle O p R = \frac{1}{9}fbd^2$ becomes the equation of equilibrium, W representing the weight which will just break the beam; and when $\angle O p R$, or the deflection, is small, its cosine may be considered as equal to unity. It follows that the strength by which beams of the like material resist this kind of strain will vary as $\frac{bd^2}{l}$.

If a perfectly elastic beam or bar were attached horizontally at one end to a wall, and were strained by a weight W at the other end, the mathematical theory would give for the deflection of the opposite end of the beam (that is, the distance to which this end would be drawn in a vertical direction from the original position of the beam) $\Delta = \frac{W.l}{ad^3\delta}$ (Poisson, *Mécanique*, tom. i., No. 310), where Δ = that deflection; l = the length of the beam; a = the area of the transverse section; d = the depth; and δ = the element of deflection. Therefore, if Δ be found from experiment on a beam or bar in which W , l , a , d , are given, we may from this equation obtain δ ; and subsequently the value of Δ may be found for any beam, the materials being of the same kind. Again, the straining power by which a beam fixed at one end to a wall is dilated in the direction of its length is expressed by $a\delta D$ (*Ib.*, No. 308), where D is the element of dilatation. Now, if w be the weight which would produce the deflection δ and dilatation D , we should have $w = a\delta D$; whence $\frac{D}{w} = \frac{1}{a\delta}$; and the first member of this equation being substituted for its equivalent in the above expression for Δ , the latter becomes $\Delta = \frac{D.W.l^2}{wd^3}$; or since the elongation of the whole beam is proportional to

the length, and may be represented by $D.l$, if we put E for this elongation when $w = W$, we shall have $\Delta = E \frac{l^2}{d^3}$.

Whence the elongation of an elastic rod by a weight or power acting in the direction of its length is to the deflection of the same rod by a weight or power acting perpendicularly to its length, as the square of the depth or thickness is to the square of the length.

The relations between the strength and strain when a beam or bar, as MN in the preceding figure, is fixed at one end in a wall, and when a beam, as $P'MP$ in the annexed diagram (*fig. 2*), of equal dimensions with respect to breadth

Fig. 2.

and depth, but twice as long, is supported on a prop at its middle point (the weight at each extremity of the latter being equal to that at the extremity of the former), are the same. Also the angle $VO P$ of deflection (OV being in the direction of $P'O$ produced), when a beam is supported on a prop at Q , is equal to $\angle O p R$, or $\angle H O p$, in the preceding figure (OH being drawn perpendicular to the wall, or parallel to the horizon, and the beam MN being equal in every respect to one of the half-beams on the prop). For the angles MOm are equal in both cases; since the weight at P' produces only the same effect as the reaction of the wall: and hence it follows that the angle $H O P$ of deflection, with respect to the horizontal line $II'H$, will be equal to only half the angle $II O p$. The same relation subsists between the deflections when the beam $P'MP$ is supported on the props at the extremities.

It will follow, from what was at first stated, that a beam attached at one end to a wall in a horizontal position will bear suspended from the other extremity only half the weight which the same beam will bear on its middle point when made to rest loosely on the two props. If the ends of the beam were prevented from rising on the props, the strength would, on account of the additional weight necessary to produce deflection or fracture at each end, be increased in the ratio of 3 to 2 nearly.

The following table contains a few of the results obtained from experiments made by Messrs. Banks, Barlow, and Tredgold, on wood and iron, when supported loosely on props and subject to a transverse strain at the middle point. The second column contains the length of the beam or bar in feet; the third, the areas of the transverse sections in square inches; the fourth, the breaking weights in pounds; and the last, the deflections at the middle points in inches.

Since the strengths of beams attached at one end or supported on props, the other dimensions being the same, vary as the squares of the vertical depths, it follows that the most advantageous position, when the areas of the transverse sections are equal, is that in which the broadest surface is in a vertical position. In this manner girders and joists in edifices are invariably placed.

When a beam or bar is attached at one end to a wall, or when it turns upon its middle point like the great lever of a steam-engine, if it be required that the beam should be equally strong in its whole length, it should be made to taper towards its extremities. When the depth of the beam is constant, the breadth at any point should be proportional to its distance from the extremity. When the breadth is to be constant, the vertical face of the beam should have the form of the common parabola; and when both breadth and depth vary, a longitudinal section of the beam should have the figure of that which is called a cubical parabola.

If a weight be applied at any point in the length of a beam which is supported on two props, the strain produced by it will be the greatest when it is placed in the middle; and the strain varies as the product of the distances of the weight

from the points of support. For let AB (*fig. 3*) represent

Fig. 3.

A P C P' B

a beam supported at A and B , and let C be any point in it. Imagine a weight W to be applied at any point P ; then, by the nature of the lever, $AB : PB :: W$; the pressure

exerted by W on the point A , viz. $\frac{W \cdot PB}{AB}$; and this term expresses the reaction of the prop at A in consequence of the

weight at P . Then also $\frac{W \cdot PB}{AB} \cdot AC$ is equal to the strain at C produced by this reaction. Again, imagine a weight W' to be applied at P' ; then we shall have, as before,

$AB : P'A :: W' : \frac{W' \cdot P'A}{AB}$, and this last term expresses the reaction of the prop at B in consequence of the weight

at P' : also $\frac{W' \cdot P'A}{AB} \cdot BC$ is equal to the strain at C produced by this reaction. The sum of these strains is equal to the whole strain at C produced by the two weights. But

when P and P' coincide with C , we have $P'A = AC$, $PB =$

BC ; and the sum of the two strains is $\frac{W \cdot BC \cdot AC}{AB} + \frac{W' \cdot AC \cdot BC}{AB}$

; or, putting W'' for $W + W'$, we have the strain at C , in consequence of the weight W'' placed there,

equal to $W'' \cdot \frac{AC \cdot BC}{AB}$; and if W'' be a constant weight

applied at any point in AB , the strain will vary as $AC \cdot BC$. This rectangle, and consequently the strain, is a maximum when C is in the middle of the line.

If a weight be diffused over a beam which is fixed at one end to a wall, it may be considered as acting at its centre of gravity, which, if the diffusion be uniform, will be in the middle of the length of the beam. The momentum of the strain will consequently be equal to half of that which would result from an equal weight attached to the opposite end.

When a body is compressed in a direction perpendicular to the length of the fibres, the points of support being very near and on opposite sides of the place at which the force is applied, the strain to which the body is then subject has been called by Dr. Young the force of detrusion. This species of strain sometimes occurs in the construction of machinery; but few experiments have yet been made to determine the strength by which materials resist it. From these however it appears that the strength is proportional to the area of the transverse section, and that it varies from four-thirds to twice the strength by which the same material would resist a strain in the direction of its length.

Such machines as capstans and windlasses, also axles which revolve with their wheels, are, when in action, subject to be twisted, so that their fibres tend to become curved in oblique directions; and the strain thus produced is called that of torsion. The most natural way of investigating the strength of materials to resist this kind of strain is probably that which was adopted by Dr. Robison: this mechanician imagined the cylindrical body to be composed of an infinite number of concentric hollow cylinders inserted in each other; and, supposing the whole to be cut by a plane perpendicular to the axis, he conceived that two particles in the circumference of any one of the concentric circles would resist the effort to separate them, by a force proportional to their distance from the common axis. Hence, if the radius of the whole cylinder be r , and that of any one of the internal cylinders be x ; also, if F' represent the force of cohesion between any two particles in the outer circumference,

we have $r : F' :: x : \frac{F'}{r} x$. The last term expresses the like force in the circumference of the cylinder, whose radius

is x , and the momentum of cohesion is $\frac{F'}{r} x^2$. But as all the particles in that circumference exert the same power, and the number of particles is proportional to x , it follows

that $\frac{F'}{r} x^2$ will represent the sum of all the forces in the

latter circumference, and $\frac{F'}{r} x^2 dx$ will represent the sum

in a hollow cylinder whose thickness, in the direction of the radius, is infinitely small and equal to dx . Then, by the rules of integration, we have for the strength of the whole

cylinder the expression $\frac{F'}{4r} x^4$, which, between $x = 0$ and

$x = r$, becomes $\frac{F'}{4} r^3$; and hence the whole strength of any

cylinder varies as the cube of the radius.

But the area of any section of a cylinder whose radius is r being $= r^2 \pi$ (π being the half circumference of a circle when the radius $= 1$), it is evident that $F' r^2 \pi$ will represent the lateral cohesion by which all the particles resist being separated by the force of detrusion. Therefore the ratio between the force of detrusion and that of torsion will be as

$r^2 \pi$ to r^3 or as 4π to r .

And since the strength under the latter strain depends on the radius, it is evident that a hollow cylinder must be stronger than a solid one; the areas of the material in the transverse sections being equal to each other.

MATHEMATICS ($\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$, or $\mu\acute{\alpha}\theta\eta\mu\alpha$), a name given in the first instance to a branch of knowledge, not as descriptive of its subject-matter, but of the methods and consequences of learning it. The word $\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$, and the Latin *disciplina*, by which it has been rendered, have been the origin of the vernacular terms *mathematics* and *discipline*, the meanings of which have long since separated. The properties of space and number, the subject-matters of the $\mu\acute{\alpha}\theta\eta\sigma\iota\varsigma$, have usurped the name; so that anything which relates to them, however learnt, is called mathematics: the Latin word, on the contrary, still retains the signification of a corrective process; and, in speaking of any branch of knowledge, is applied when power of mind is derived from the methods of learning it, as well as knowledge from the results.

The original use of the word mathematics cannot be gathered, as far as we can find, from any express contemporary authority; a few passages, in which the term is used without explanation, as one of notoriety, being all that can be cited, and mostly from Plato. Later writers, as for instance Anatolius (cited by Heilbronner), A.D. 270, give the derivation above alluded to. But before the time of the last-named writer the meaning of the word had been extended: thus the book of Sextus Empiricus 'against the mathematicians' is, as Vossius remarks, directed as much against grammarians and musicians as against arithmeticians and geometers. And John Tzetzes, in the twelfth century, includes under the $\mu\alpha\theta\eta\mu\alpha\tau\alpha$ nearly what the universities afterwards called by the name of arts; calling grammar, rhetoric, and philosophy, the disciplines ($\mu\alpha\theta\eta\mu\alpha\tau\alpha$), and arithmetic, music, geometry, and astronomy, arts ($\tau\epsilon\chi\eta\alpha\iota$), included under philosophy.

The distinction between the old and new meaning of mathematics is most requisite to be kept in mind, because arguments are frequently urged for and against mathematics, in which the discipline is confounded with the communication of facts and processes about space and number; and because it is our intention in the present article, confining ourselves to the most important view of the science, as well as to the etymological meaning of its name, to offer a few remarks on the *discipline* called mathematics.

In the time of Plato, which was probably that of the application of words which imply 'the discipline' to that one exercise of mind which consists in making deductions by pure reasoning from the self-evident properties of space and number, it is probable that such restriction of the word was easily justifiable. At present we have, besides mathematics, physics, the study of antiquity, grammar, &c., which have all been made disciplines, but no one of which was then entitled to that appellation. Nevertheless it has happened that writers, misled partly by the name of mathematics and partly by the pre-eminence of mathematical reasoning in strictness and connexion, have spoken as if it were the *only* cultivator of the pure reasoning power.

Much discussion has arisen upon the question whether those primary propositions which, from our clear apprehension and willing admission of them, are called self-evident, are notions inherent in the mind, or deductions of early experience. Except to mention this controversy, we have here nothing to do with it. The certainty of these propositions is all that we want, and this is conceded by both sides. The consideration however of the fundamental supports of ma-

thematical reasoning is useful and interesting, and, as a safeguard, even necessary. It is not long since a school of metaphysicians existed, who imagined that because all mathematical definitions are precise, therefore the exact sciences are founded upon definition. It was not to them a necessary result of the constitution of our faculties that the three angles of every triangle make up the same amount, but a consequence of definition, which might have been something else, upon different suppositions. We can hardly undertake to explain what we do not understand, but we recommend every beginner in the subject to seek no knowledge about the character of fundamental propositions until he shall have become well acquainted with their consequences. He must take care to admit nothing which is not, or cannot be made, most evidently true; and he will find that all axioms, as they are called, have the highest sort of certainty, namely, that they cannot be imagined otherwise.

Whatever may be the metaphysical hypothesis to which it is referred, it is certain that there is a real distinction between a mathematical assertion and one of any other kind. If we say that an unsupported bit of lead will fall to the ground, we state a fact of which we are as certain, in the sense of reliance, as we are of the other proposition that two straight lines cannot enclose a space. But in the former proposition, an exception, or even a permanent alteration of the law, is conceivable by the imagination: in the latter the mind would feel sensible of absurdity if it attempted to construct the idea of an enclosure bounded by only two straight lines. No distinctive phrases can be too strong to express the essential difference of these two assertions; but it is a misfortune that all terms which create a sufficient distinction are linked to one or another theory of the human mind. If the mathematical student can receive these terms as indicative of the difference of species, without bending before an hypothesis about the conformation of his own reason, he will do well to adopt them; if, on the other hand, he feel compelled to agree with any one system of mental philosophy, he will neither impede nor advance his mathematical career.

The sciences of which we speak may be considered either as disciplines of the mind, or as instruments in the investigation of nature and the advancement of the arts. In the former point of view their object is to strengthen the power of logical deduction by frequent examples; to give a view of the difference between reasoning on probable premises and on certain ones, by the construction of a body of results which in no case involve any of the uncertainty arising from the previous introduction of that which may be false; to form the habit of applying the attention closely to difficulties which can only be conquered by thought, and over which the victory is certain if the right means be used; to establish confidence in abstract reasoning by the exhibition of processes whose results may be verified in many different ways; to help in enabling the student to acquire correct notions and habits of generalisation; to give caution in receiving that which at first sight appears good reasoning; to instil a correct estimate of the powers of the mind, by pointing out the enormous extent of the consequences which may be developed out of a few of its most inherent notions, and its utter incapacity to imagine, much less to attain, the boundary of knowledge; to methodise the invention of the means of expressing thought, and to make apparent the advantages of system and analogy in the formation of language and symbols; to sharpen the power of investigation, and the faculty of suggesting new combinations of the resources of thought; to enable the historical student to look at men of different races, opinions, and habits, in those parts of their minds where it might be supposed *a priori* that all would most nearly agree; and to give the luxury of pursuing a study in which self-interest cannot lay down premises nor deduce conclusions.

As instruments in the investigation of nature and the advancement of the arts, it is the object of the mathematical sciences to give correct habits of judgment and ready means of expression in matters involving degree and magnitude of all kinds; to teach the method of combining phenomena, and ascending from the complicated forms of manifestation to the simple law which regulates them; to trace the necessary consequences of any law, assumed on suspicion, in order to compare those consequences with phenomena; to construct hypothetical representations of laws, or approximations to laws, which shall sufficiently represent pheno-

mena; to convert processes of known accuracy, but complicated operation, into others which make up in simplicity for a certain amount of inaccuracy, and to devise means for judging of that amount of inaccuracy, and confining it within given limits; to ascertain the most probable result of observations or experiments which are discordant with each other either from errors of measurement or unknown causes of disturbance; to point out the species of experiments which should be made to obtain a particular sort of information, or to decide between two laws which existing phenomena both indicate as of nearly equal credibility; to make all those investigations, which are necessary for the calculation of results to be used in practice, as in nautical astronomy, application of force and machinery, and conduct of money transactions; in a word, though that word by itself would have not presented a sufficiently precise idea, to find out truth in every matter in which nature is to be investigated, or her powers and those of the mind to be applied to the physical progress of the human race, or their advancement in the knowledge of the material creation.

The main branches of mathematical science were formerly stated to be arithmetic and geometry, springing out of the simple notions of number and space. This is too limited a description. Unquestionably the science of numbers, strictly and demonstratively treated, and that of geometry, or the deduction of the elementary properties of figure from definitions which are entirely exclusive of numerical considerations, must be considered as the elementary foundations, but not as the ultimate divisions, of mathematics. To them we must add the science of operation, or algebra in its widest sense,—the method of deducing from symbols which imply operations on magnitude, and which are to be used in a given manner, the consequences of the fundamental definitions. The leading idea of this science is operation or process, just as number is that of arithmetic, and space and figure of geometry: it is of a more abstract and refined character than the latter two, only because it does not immediately address itself to notions which are formed in the common routine of life. It is the most exact of the exact sciences, according to the idea of their exactness which is frequently entertained, being more nearly based upon definition than either arithmetic or geometry. It is true that the definitions must be such as to present results which admit of application to number, space, force, time, &c., or the science, would be useless in mathematics, commonly so called; but it is not the less true that a system of methods of operation, based upon general definitions, and conducted by strict logic, may be made to apply either to arithmetic or geometry, according to the manner in which the generalities of the definition are afterwards made specific.

The common division however of the mathematical sciences will not admit of the threefold separation just described, the science of operation being more or less mixed up with arithmetic in common algebra, and in its application to geometry. We may describe this division as follows:—

1. *Pure Arithmetic*, subdivided into *particular* and *universal*:* the former, the common science of numbers (integral and fractional) and calculation; the latter, the science of numbers with general symbols, or the introduction to algebraical methods, restricted to purely numerical processes. The science which treats of the peculiar relations of numbers, and subdivides them into classes possessing distinct properties, is called the *theory of numbers*, and is an extension which frequently requires a higher algebra.

2. *Pure Geometry*, which investigates the properties of figures in the manner of Euclid, that is, with restrictions which confine the student to the straight line and circle as the means of operation and the boundaries of figure. [GEOMETRY, p. 153.] This science includes solid geometry, as far as figures bounded by planes, the properties of the sphere, cone, and cylinder, and of their plane sections; but it does not allow any conic section, except the straight line and circle, to be employed in the solution of problems.

3. *Algebra*, including the general calculus of operations (though this is not an elementary branch), and all methods which can be established without the aid of processes exclusively belonging to the differential calculus. The distinction between it and universal arithmetic is an extended use of operations, preceded by an extended definition of their meaning.

* We have supplied the word particular, as opposed to universal; algebra was sometimes called universal arithmetic, but the phrase never became general, owing to its being obvious to those who studied algebra, that arithmetic, however general its symbols may be, is only a part of algebra.

4. *Application of Algebra to Geometry.*—This includes *trigonometry*, and all those parts of geometry in which problems are numerically solved, and the method of Euclid is abandoned. Thus it includes the conic sections as commonly taught; and in its higher parts is an application of the differential calculus, as well as of algebra.

5. *Differential and Integral Calculus.*—Under this term we include the general theory of limits, that is, all digested methods of operation, in which the limits of ratios are used as algebraical quantities under specific symbols. This distinction is necessary, since the notion of a limit, and even propositions which belong to the differential calculus in everything but form, are contained in the elements of Euclid, and the application of arithmetic to geometry. The *calculus of differences* and the *calculus of variations* are usually placed under this head: the former, in its elementary parts, might be referred to common algebra; the latter is an extension of the differential calculus.

The division of the mathematical sciences into *pure* and *mixed* is convenient in some respects, though liable to lead to mistake. By the former term is understood arithmetic, geometry, and all the preceding list; by the latter, their application to the sciences which have matter for their subject, to mechanics, optics, &c. But considering that in all these subjects a few simple principles are the groundwork of the whole deduction, they might be explained as intended to answer two distinct questions: first, what are the consequences of such and such assumptions upon the constitution of matter? secondly, are these consequences found to be true of matter as it exists, and are the assumptions therefore to be also regarded as true? In the reply to the first question, the science is wholly mathematical; to the second, wholly experimental in its processes, and inductive in its reasonings; and this is the *mixture* from which the joint answer to both questions derives its name, and not from any difference between its mathematics and those of the pure sciences. Again, a science does not take the name of mixed mathematics simply because it is possible to apply mathematical and in the furtherance of its legitimate conclusions: such a use of terms would be trifling with distinctions, since it would bring political economy, chemistry, geology, and almost every part of natural knowledge, under the same head as mechanics and hydrostatics. The words in question should be reserved to denote those branches of inquiry in which few and simple axioms are mathematically shown to be sufficient for the deduction, if not of all phenomena, at least of all which are most prominent. Taking the leading ideas of the mixed sciences instead of their technical names, we may describe them as relating to motion, pressure, resistance, light, heat, sound, electricity, and magnetism. As disciplines, it is their main object to teach the true method of inquiry into the laws, and, so far as can be known, the causes, of material phenomena; as instruments, it is not necessary to say one word about them. Two only have not been mentioned: the first, astronomy, which belongs to more than one of the preceding; the second, the theory of probabilities, of which, though placed among the mixed sciences, it may be doubted whether its proper place is not in the first list.

The most important question connected with the mathematical sciences is the manner in which they should be taught as disciplines of the mind. This concerns all who consider any branch of knowledge in that light; and, as education spreads, this view of the subject will become of more and more consequence. Vitally essential as these sciences are to the advancement of the arts of life, we feel, in regard to this branch of their utility, in the situation of those who know that they must and will be attended to, because their cultivation is necessary to the supply of wants which all can feel, and the promotion of interests which all can understand. It is not so with the first-mentioned object of their study, but rather the reverse; for the wants of life being as easily supplied by the results of an illogical as of a logical system (provided only that vicious reasoning be not allowed to produce absolute falsehood), the facilities which laxity of reasoning affords in the mere attainment of results will always recommend it to those whose main object it is to apply the fruits of calculation to the uses of life. Such has been, and, we are afraid, will continue to be, the tendency of the great advance which the last century made in application.

All we should positively contend for is the necessity of making the entrance to the study as strict and rigorous as

reason can make it, to all who are to receive liberal education. In the higher branches of mathematics many opinions prevail, and it would be impossible to make a formal standard of rigour. Add to this, that with a certain degree of experience in the estimation of reasoning, it may be comparatively immaterial which of several different methods is adopted; either may be rigorous if properly understood, and if the habit of reducing looseness of phraseology, or dangerous abbreviation of logic, to strict definition and formal deduction, shall first have been well formed. To assist in gaining this end, we should propose—

First, that no student should be allowed to enter upon the use of language in mathematical reasoning until he has acquired more acquaintance with the nature of assertion, denial, and deduction, than can be obtained from previous education as now given: this to be done by the study of the elements of logic.

Secondly, that no consideration of facility or practical convenience should prevent the first study of arithmetic and geometry from being strictly demonstrative, and formally rigorous: rigour being defined to consist in explicit statement of every assumption, and logical treatment of every inference.

On the first of the preceding recommendations we shall only observe, that in order to distinguish between accurate and inaccurate inference, an acquaintance with the exact extent of meaning of the several modes of communication is absolutely necessary. This cannot be learnt from the ordinary use of language, which abounds in implications to be suggested by the circumstances of the speaker, the context of the words, or the tone in which they are delivered. Before the phrases of demonstration can be made to convey a meaning limited in both directions, the strict use of language must be made a study; if this be neglected, the words of any book may pass between the teacher and the learner, but no precaution has been taken to secure their conveying the proper meaning, neither too much nor too little.

On the second recommendation, we must first explain that we hold many points of controversy very cheap, as far as they concern the discipline given by the most elementary branches of mathematics. It matters nothing, in our view of the case, whether an axiom be really incapable of proof, or whether the substitution of another would or would not place the science on a more simple basis. The habit to be formed is that of tracing necessary consequences from given premises by elementary logical steps: the premises to be true or false, the consequences to be true if the premises be true, and dubious (not necessarily false) if the premises be false. The only error which, at the stage in question, it is intended to avoid, is the deduction, as a necessary consequence, of that which is not so. The mind of the learner however is allowed to dwell too much at the outset on the absolute truth or falsehood of the conclusions, to the neglect of their connection with the premises: hence it arises that when a process occurs in which it is essential to examine that connection for its own sake, it is the universal complaint that beginners find difficulty and obscurity. From what other cause arises the dislike of the indirect demonstration? [ABSURDUM, REDUCTIO AD.]

Unfortunately for the mental progress of the student, he is often allowed to use premises of an easy form, in cases where a complete preparation for the subject would require more extended first principles and greater prolixity of deduction. To this, as before observed, no objection can be taken in itself, provided that no consequences be admitted except the legitimate ones. But something more is admitted: the pupil is presented, in consideration of his attention to one set of premises, with the consequences of another, and is allowed to make believe that he has come fairly by the latter. Thus, by a theory which applies only to the ratio of number to number, he is permitted to draw general conclusions upon all ratios. When, in opposition, we advise that the first studies should be demonstrative and rigorous, we do not imply, for instance, that the more difficult system should in all cases be preferred to the less complete but more simple: we confine ourselves to insisting that whatever the premises may be, the conclusions should really follow; and that if the latter be necessarily of a limited character, the limitation should be stated.

The work of Euclid is preferable, in our opinion, to any system which has been proposed to supply its place; simply because the dependence of conclusions upon premises is more distinct than in any other geometrical writing. Tho

defects with which it abounds are trifles which can be remedied as they are met with; and though there are seldom three propositions together, one or other of which will not call for some remark from the teacher, yet such is Euclid, that these very faults, properly noted, are of more value than the greater elegance and more artificial process of less formally rigorous writers. Of the part relating to PROPORTION we shall treat under that word.

The necessity of a demonstrative system of arithmetic is practically denied, in this country at least, by the use of a set of dogmatical rules. Such training would be less prejudicial if the notions of the student on reasoning were more settled, so that he could receive these rules with some fitting idea of their purpose, and of the extent to which they are to be considered as knowledge. As it is, he has no other view of arithmetic presented to him, and his conceptions of number are allowed to be first fettered, and afterwards led astray, by ideas derived sometimes from the reception of the conventional for the necessary, sometimes from modifications of truth which are convenient in practice though unsound in theory. Such an addition to his stock of mathematical power predisposes him to acquiesce in the shifts by which rigour is avoided in other parts of the science; and an arithmetic from which both sequence and accuracy of thought have been excluded is the asylum of geometry against truth, when the latter becomes too difficult for an unenergetic, that is untrained, power of investigation.

We shall conclude this article with some references to works on the history of mathematics, a subject so connected with that of the other sciences, that it would be impossible to say anything on it in few words. The great work of Montucla, continued (from his papers partly) by Lalande, '*Histoire des Mathématiques*,' 4 vols., Paris, 1799-1802, is the most accessible source of information for the reader who desires some detail. The bibliography of Murhard, '*Litteratur der Mathematischen Wissenschaften*,' Leipzig, 1797, will be found a useful accompaniment in the verification of dates. The work of Küstner, '*Geschichte der Mathematik*,' Göttingen, 1796, is more precise in its account of individual labours than that of Montucla, but does not embrace so large a field. The works of Bossut, namely, the preface to the mathematical part of the '*Encyclopédie Méthodique*' and the '*Histoire des Mathématiques*,' 2 vols. 8vo., Paris, 1810, are written in an interesting manner; and the latter (which was translated by Bonnycastle) brings some parts of the history later than its predecessors. Cossali's '*Origine dell' Algebra*,' 2 vols. 4to., Parma, 1799, is an account of the early Italian algebra: its successor in the same subject, '*Histoire des Sciences Mathématiques en Italie*,' Paris, 1838, by M. Libri (of which two volumes only have appeared, four more being understood as intended), bids fair to be very valuable from the number and extent of the citations. Much on the subjects of algebra, logarithms, and trigonometrical tables may be found in Dr. Hutton's Tracts (3 vols. 8vo., 1812), and in the preface of his Logarithms. The work of Montucla, '*Récherches sur la Quadrature du Cercle*,' reprinted with additions in 1831, is complete on the subject of which it treats. There is a work on a kindred subject which we have never seen, Reimer, '*Historia Problematis de Cubi Duplicatione*,' Göttingen, 1798. Delambre's '*Rapport Historique sur les Progrès des Mathématiques depuis 1789*,' Paris, 1810, is the least specific of his historical works, but, points of nationality apart, is accurate. Professor Peacock's article on arithmetic in the '*Encyclopædia Metropolitana*,' and his report on Analysis, in the second volume of the '*Transactions of the British Association*,' are full of historical information of the most precise character. Some notices of early English mathematicians, enough to guide the reader to sources of information, are contained in the '*Companion to the Almanac*' for 1837, and in the '*Magazine of popular Science*,' Nos. 18, 20, and 22. The eleventh volume of the '*Memoirs of the Academy of Brussels*' contains the '*Aperçu Historique*,' &c. of M. Chasles, a history of geometry and a complete account of its modern progress.

Among works of older date, which are often cited, we may notice Ward's '*Lives of the Gresham Professors*,' London, 1760; Heilbronner's '*Historia Matheseos Universæ*,' Leipzig, 1742, does not deserve that title, but contains an immense quantity of information on the antient part; G. J. Vossius, '*De quatuor Artibus popularibus*,' Amsterdam, 1650, contains a large number of dates and short biographical accounts; to Blancanus, '*De Mathematicarum*

Naturâ Dissertatio,' Bologna, 1615, is appended a chronological list of mathematicians up to the time of Galileo; the '*Scolæ Mathematicæ*' of Peter Ramus, Frankfort, 1627, contains many historical notices. The number of writings which might be referred to as incidentally affording information is of course numerous.

MATHEWS, CHARLES, an eminent comedian, was born on the 28th of June, 1776, and educated at Merchant Tailors' School. His father, Mr. James Mathews, was a bookseller in the Strand, and intended Charles, who was his seventh son, to follow the business. A strong and early inclination for the stage however induced the son, after two or three attempts in private, to make his début as an amateur in the parts of Richmond in '*Richard III.*,' and Bowkit in '*The Son-in-Law*,' at the Richmond theatre, Saturday, Sept. 7, 1793; and on the 19th of June, 1794, he made his first appearance as a regular comedian at the Theatre-royal, Dublin, for the benefit of Mrs. Wells, and in the characters of Jacob in '*The Chapter of Accidents*,' and Lingo in '*The Agreeable Surprise*.' In 1797 Mr. Mathews married his first wife, Miss Eliza Kirkham Strong, the daughter of a physician at Exeter. She died at York in 1802; and in 1803 Mr. Mathews was united to his second and surviving wife, Miss Anne Jackson, at that time a member with himself of the York company. On the 15th of May in the same year Mr. Mathews made his first bow to a London audience at the Haymarket theatre, and on the 17th of September, 1804, his first appearance at Drury-Lane, in the character of Don Manuel, in '*She would and she would not*.' On Wednesday, April 12, 1808, at the Theatre-royal, Hull, he made his first trial of those popular performances, his '*Entertainments*' and '*At Homes*,' by the recital of his '*Mail-Coach Adventures, or Rambles in Yorkshire*.' On the 22nd of July, 1814, Mr. Mathews was severely injured by being thrown out of a tilbury in which he was driving his friend Mr. Terry. The effects of this unfortunate accident he felt to the last day of his life. On the 2nd of April, 1818, he commenced his extraordinary engagement with Mr. Arnold of the English Opera House, and gave his first '*At Home*' in London, an entertainment which he repeated thirty-nine nights to overflowing houses. In 1822 he paid his first visit to New York, returned to England in the following year, and in 1824 produced his entertainment entitled '*A Trip to America*.' In January, 1828, he accepted a short engagement at Drury-Lane, and in the autumn of the same year became joint proprietor with Mr. Yates of the Adelphi theatre, by the purchase of his deceased friend Mr. Terry's share. In 1834 he again visited America, but was compelled by ill health to return prematurely, having played only thirty nights. On Tuesday, 28th of June, 1835 (his birth-day), he expired at Plymouth, after considerable suffering, aged fifty-nine, and was buried in the vestibule of St. Andrew's church in that town. As a comedian Mr. Mathews ranked deservedly high; but his greatest popularity was certainly achieved by his wonderful talent for personation and imitation, in the exercise of which his kind heart as well as good taste kept him guiltless of offence even to the most sensitive of those whose peculiarities of voice, manner, or person he so happily assumed. In private life Mr. Mathews was universally respected, and with him the stage lost a perfect gentleman as well as a distinguished professor. His memoirs, partly autobiographical, and edited by his widow, have been recently published in 8vo.

MATHIOLA, a genus of cruciferous plants with tapering pods, converging stigmas thickened at the back, a calyx with two saccate sepals, and compressed seeds arranged in a single row and surrounded by a thin membranous border. It consists of annual and perennial herbaceous plants inhabiting the warm countries bordering the Mediterranean, and extending eastwards into Persia and some of the southern Asiatic provinces of Russia. Between thirty and forty species are known to botanists, among which are those which form the stocks and gilliflowers of gardens, sweet scented biennials much valued for the beauty and variety of their many-coloured flowers. The principal source of these has been *Mathiola incana*, to which are to be assigned the hoary-leaved, or ten-week stocks; Brompton, and queen's; and *M. glabrata*, which comprehends the smooth-leaved, or green wallflower-leaved stocks: it is however probable that the numerous varieties now common in gardens under the name of German and Russian stocks have been procured, at least in part, by muling the former species with some of the sad-coloured species of the genus. The

latter are called Luperias by De Candolle, and are remarkable for their dingy flowers, which are exceedingly fragrant at night, but at no other time. *M. livida*, *tristis*, and *L. odoratissima* are the best known of them, and are frequently cultivated in greenhouses.

MATILDA, or MAUD, Empress. [HENRY I., II.]

MATILDA, Countess of Tuscany. [GREGORY VII.]

MATLOCK. [DERBYSHIRE.]

MATRASS, a glass chemical vessel, employed for the purpose of digesting, boiling, and distillation, and sometimes while one is used as the body, another serves as the receiver in the last-mentioned operation. Florence flasks are very commonly used for these purposes, and they answer admirably, on account of the excellent nature of the glass, which is such as to resist the effects of sudden alterations of temperature. Sometimes matrasses are very conveniently formed with flat bottoms, instead of their being round as in oil-flasks.

MATRIX, or GANGUE. Metallic ores are seldom found unmixed in the places in which they occur; they not only accompany each other, but are frequently associated with useless stony bodies, and these are called the matrix, or gangue.

It also happens that ores in some cases become gangues with relation to more precious minerals; those which may be distinguished as metallic gangues are iron pyrites, spathose iron-ore, oxide of iron, hydrate of iron, and blende; the earthy gangues are usually quartz, felspar, limestone, carbonate of barytes, sulphate of lime, sulphate of barytes, and fluor-spar.

MATRONS, JURY OF. When a widow alleges herself to be with child by her late husband, and it is suspected that she is not pregnant, or not so by the husband, a writ de ventre inspiciendo may be obtained out of chancery, on behalf of the next heir, whose rights might be prejudiced by a supposititious, or spurious, child. Under this writ a jury of 'discreet and lawful women' is impanelled, to try, by inspection of her person (et ubera et ventrem tractando), whether the widow is with child or not, and if with child, to inquire of the time of conception, and of that of the expected delivery. If the widow be found to be pregnant, the sheriff, on returning the writ, certifies the court of common pleas to this effect; whereupon the widow, unless she be remarried (in which case she is not to be taken from her husband), is to be kept in a castle, or other safe place, until her delivery, in order, as far as possible, to prevent any child being improperly introduced as the issue of the husband, to the disherison of the heir. (Bracton, lib. 2, cap. 32; Croke, Eliz., 566; 6 Vesey, 260; 21 Viner's Abr., 547.)

In the parliament roll of 9 Edw. II. (1 Rot. Parl., 353, 354), is a curious proceeding, instituted on the 13th July, 1315, by the sisters and coheirs of Gilbert de Clare, earl of Gloucester, who had died on the 30th June, 1314, to recover their inheritance out of the king's hands, notwithstanding the alleged pregnancy of the countess, his widow. At the parliament held in January following (more than eighteen months after the death of the earl), the king's sergeants insisted that it was still the duty of the crown to retain possession of the estate for the benefit of the expected offspring, whose birth had *from natural causes* (permittente natura) been so long deferred; and it was not until Easter term, 1316, that the impediment was treated as removed.

A jury of matrons is also summoned to inquire into the fact of pregnancy in cases where a woman convicted of treason or felony, upon sentence of death being pronounced, pleads, in stay of execution, that she is with child. If the matrons impanelled to try this allegation find it to be true, the convict, whether she be married or unmarried, is respited until after her delivery. In some of the cases reported, the matrons have been directed to inquire whether the convict is *quick* with child; in other cases, and those by far more numerous, the inquiry seems to have been general, namely, *pregnant* or not pregnant. (Hawkins, P. C., book ii., cap. 51, sec. 9.) As the child is now known to have the same degree of foetal life before as after the change of position which occasions the sensation called quickening, the latter form of the inquiry appears to be not only the more humane but also the more correct; more especially as the law has now rejected the distinction between quick and not quick, in cases of attempts to procure abortion. (7 Will. IV. & 1 Vict., c. 85, s. 6.) After delivery the convict is not to be executed without an award of execution by the court. But when called upon to say why execution should not be

awarded against her, the convict cannot plead that she is again with child; such further pregnancy being considered not to be a sufficient ground for suspending, for a second time, the execution of the sentence. The gaoler is, under such circumstances, punishable for his negligence. But if the ground of the first postponement was the preservation of the infant, there seems to be no reason why the life of the second child should be sacrificed.

The form of proceeding where a woman alleges herself to be with child by her late husband, which is described in the passage of Bracton already referred to, is evidently taken from the Roman form of proceeding in a similar case, as described in *Dig.* 25, tit. 4, 'De Inspiciendo Ventre, custodiendo Partu.'

MATSYS, QUINTIN, an eminent painter, born at Antwerp in 1460, is said to have followed the trade of a blacksmith or farrier till he was at least twenty years of age. His quitting his trade to take up painting has been ascribed to different causes. The story that has gained most credit (perhaps because it is the most romantic) is that he fell in love with a young woman whose father was resolved she should marry none but an artist. At all events he appears to have had great talents: his manner is singular, and different from that of any other master; his design is correct and true to nature, and his colouring forcible. His pictures are carefully finished, though rather dry and hard. It is thought by competent judges, that if he had been in Italy, and studied the antique and the great masters of the Roman school, he would have been one of the most eminent painters of the Low Countries. Though he generally took his subjects from ordinary life, he sometimes ventured with success into the higher departments of the art. One instance of this is a 'Descent from the Cross,' painted for the cathedral of Antwerp, and now in the museum of that city. His most remarkable and best known picture is that of the 'Two Misers,' of which there are numerous copies. The picture in the Royal Gallery at Windsor is supposed to be the original, but Dr. Waagen does not think it equal to its reputation. On the other hand he speaks in the highest terms of a 'Mary Magdalen,' half-length, three-quarters the size of life, in the gallery at Corsham House, the seat of Lord Methuen. His drawings are extremely rare. He died at Antwerp in 1529.

MATTER is the name given to every thing which is not mind. Such seems to be the only way of defining the word; and though the definition may appear to assume that mind is not matter, the contrary of which has been contended by the class of writers called materialists, [MATERIALISM], yet it does not really do so. For whatever theory may be adopted as to the nature of mind, whether it is considered as a separate principle from matter, or merely as a different manifestation of the same principle, the word *mind* is indifferently retained; and our definition may consequently be at once reconciled with the materialist theory by paraphrasing it thus:—matter is the name given to the substance composing the universe, under all its different modifications, excepting only that one which is known by the name of mind.

Matter then is the name for that out of which all objects external to the mind are thought to be composed, the question being reserved, whether the mind is or is not composed of the same substance. What this substance is, to which the name of matter is given, we do not know, and have no means of knowing. Various speculations have been made as to its nature, and theories formed concerning the manner of its composition; but these have no better basis than conjecture. Other speculations have been made as to whether there is such a thing as matter or not; and some philosophers have seen in the solid world around us nothing but a creation of the mind. [BERKELEY; IDEALISM.]

There is no need to enter here into any of these speculations. It is sufficient to know and say that man, subject to certain affections of his senses, is led to assign those affections to an external cause. This external cause is that which he calls matter. What this matter is in itself he knows not. He knows only its capability of producing in him certain affections, the ordinary affections of the five senses (sensations, as they are called), and those which give the ideas of extension and resistance. Thus, having already supposed something without, he pronounces these to be qualities of that something; ignorant all the while what that something is, and knowing it only as the *substratum* of the qualities.

MATTHEW, ST., the Apostle and Evangelist, was a native of Galilee, and a publican or collector of customs and tribute under the Romans. While employed in his office at the city of Capernaum, he was called by Christ to follow him (*Matt.* ix. 9), and was afterwards chosen to be one of the apostles (*Matt.* x. 3). An account which corresponds in all respects to that of the conversion of Matthew as related by himself is given by *Mark* (ii. 14), and *Luke* (v. 27), respecting a publican named Levi, the son of Alphaeus. Grotius and others have supposed that Matthew and Levi were different persons, whose conversion took place at the same time; but if so, why should Matthew relate his own conversion and omit all mention of that of Levi? As the three narratives plainly refer to the same time and place, and as Levi is not mentioned among the apostles, nor in any other passage of the New Testament, we may safely conclude that Matthew and Levi are names of the same person. Perhaps Levi was his proper name and Matthew a surname given him after his conversion, as that of Peter was to Simon. The Hebrew word Matthew (*מַתְתִּי*) signifies *a gift of Jehorah*, from *מַתָּה*, *a gift*,

from *תַּתַּת*, *to give*.

In the *Acts of the Apostles* (i. 13), Matthew is mentioned with the other apostles as remaining in Jerusalem after the ascension of Christ. His subsequent history is quite uncertain. According to Socrates, an ecclesiastical historian of the fifth century, he went to Ethiopia (*Soc., Hist. Ecc.*, lib. i., c. 19); but according to another tradition, to Parthia. It has been a commonly received opinion that he was put to death at Naddabar, a city in Ethiopia (*Cave's Lives of the Apostles*, p. 178), but Heracleon, a Valentinian of the second century, mentions him among those of the apostles who escaped martyrdom. The passage is cited by Clement of Alexandria (*Stromata*, lib. iv., p. 502 B).

MATTHEW, ST., THE GOSPEL OF, is a canonical book of the New Testament, ascribed by the unanimous consent of the early Christian writers to the apostle Matthew.

It is not easy to determine the language in which this gospel was composed. That it was written in Hebrew (by which we are to understand the Syro-Chaldaic dialect spoken in Palestine in the time of Christ), and that it was composed for the Jewish Christians, is asserted by Papias (*Eusebius, Hist. Ecc.*, iii. 39), Irenæus (*Ibid.*, v. 8), Origen (*Ibid.*, vi. 25), Eusebius (*Ibid.*, iii. 24), and Jerome (*Comment. in Matt.*, *præf.*, and *De Vir. Illust.*, c. 3); and their account is followed by others of the early Christian writers. On the other hand it is argued in favour of a Greek original that these testimonies are inconclusive, for that Papias was a weak and credulous man, and that the other writers merely followed his account; that we find no traces of the actual existence of the Hebrew Gospel of Matthew, for all the quotations in the works of the early fathers are made from the Greek copy which we now have; that explanations are introduced which would be useless to Jewish readers (see *Matt.*, i. 23; xxvii. 33-46); that parallel passages of the Old Testament are generally quoted from the Septuagint; and that the Greek Gospel which we now have bears every mark of being not a translation but an original document. In order to reconcile these facts with the statements of the early writers, Dr. Whitby and others have supposed that there were *two* originals of the Gospel, one written in Hebrew for the Jewish converts, and the other in Greek for general use. They account for the absence of quotations or references to the Hebrew Gospel in the writings of the Fathers by supposing that it was corrupted by the Judaizing heretics to such a degree as to lose all authority, and that in this corrupted state it was the same document as that mentioned by Origen and other Fathers under the title of the *Gospel according to the Hebrews*. [*GOSPEL.*]

The date of St. Matthew's Gospel has been the subject of as much dispute as its original language. If it were written at first for the use of the Christians in Judæa, the date would probably be early; and it has been remarked that the exhortations which it contains to patience under persecution would be most acceptable to the Jewish Christians in their persecution by the Sanhedrim soon after the ascension of Christ. None of the early writers, except Irenæus, give any explicit testimony on the subject, but their statements appear to imply that this was the first written of the four Gospels, and also, what indeed Eusebius expressly asserts, that it was composed before Matthew left Judæa. On these grounds, and from the supposed impro-

bability of the Christians remaining long without some written account of the life of Jesus, many critics have assigned it the date of about A.D. 38.

But Irenæus says that it was put forth while Peter and Paul were preaching at Rome and laying the foundations of a church there. (*Adv. Hær.*, iii. 1, in Euseb., *Hist. Ecc.*, v. 8.) On the strength of this testimony Michaelis, Lardner, and others have fixed the date at A.D. 61 or 63, and Lardner has drawn an elaborate argument in favour of this date from the internal evidence of the book itself, in which he endeavours to show that Matthew understood many points in the Christian system which the Apostles did not understand till some considerable time after Christ's ascension. But as in these passages Matthew is recording the words and actions of Jesus, and not his own opinions, we cannot see any force in the argument.

Some of the advocates for a double original refer the Hebrew copy to the earlier date, and the Greek to the later.

The genuineness, authenticity, and canonical authority of this Gospel are established beyond dispute by the unanimous testimony of Christian writers from the earliest age, and by its place in the ancient versions. But many critics have doubted the genuineness of the first and second chapters, chiefly on account of the difference between the genealogy of Christ in the first chapter, and that given by St. Luke (iii.), and other discrepancies between these chapters and Luke's account of the early life of Christ, and other internal difficulties, and also on the ground that they were omitted in the copies used by the Nazarenes and Ebionites, which however were undoubtedly corrupt. The chief arguments on the other side are, that these chapters are contained in all the ancient MSS. and versions, that they are referred to and quoted by several of the Fathers, that the particle *ἐν* at the beginning of the third chapter shows that something had gone before, and that the style of these two chapters agrees with that of the rest of the Gospel, especially in the manner of quoting the prophecies of the Old Testament.

The general scope of St. Matthew's Gospel appears to be to show that Jesus Christ answered to the character of the predicted Messiah. It has been divided into four parts, as follows:—

Part I.—The genealogy, birth, and infancy of Christ. (Chaps. i. and ii.)

Part II.—The preaching of John the Baptist, Christ's baptism by him, and the temptation in the wilderness. (iii., iv. 1—11.)

Part III.—The public ministry of Christ. (iv. 12—xx. 16.)

Part IV.—His journey to Jerusalem, transactions there, his death and resurrection. (xx. 17—xxviii.)

The coincidences and discrepancies between this Gospel and those of Mark and Luke have been spoken of under **LUKE, MARK, and GOSPEL**.

St. Matthew was an Apostle and an eye-witness of the acts of Jesus, at least of those which were done after his call. His narrative has therefore the highest degree of credibility. His style of narration is simple and effective, and he relates the discourses of Christ with clearness, and often with great energy.

(Lardner's *Credibility* and *Lives of the Apostles and Evangelists*; Cave's *Lives of the Apostles*; Kuinoel, *Comment. in Lib. Hist. N. T. Proleg. in Matt.*; and the *Introductions* of Michaelis, Eichhorn, Do Wette, Hug, and Horne.)

MATTHEW OF WESTMINSTER, one of those valuable old writers, the Latin chroniclers of England, who have handed down to us in a simple statement of facts the deeds of the sovereigns and the persons who guided public affairs at a remote period. Matthew spent his life near the ancient palace of the kings of England, where the parliaments were usually held and the most important affairs transacted; for he was a monk of the abbey of Westminster, the church of the abbey being the usual place of interment of the kings and their families, and still remains to show of what a splendid establishment it formed a part. Matthew's date is the reign of Edward II. His history closes with the death of Edward I.; little or nothing is known of his personal history.

He entitles his work '*Flores Historiarum*.' He begins with the creation of the world, and the first and least valuable half is taken up with affairs of other countries and our own before the Conquest. Two hundred and thirty-six pages in the Frankfort edition contain the history from the Conquest to the death of Edward I. This portion is very highly esteemed.

The reigns of female sovereigns have usually been favourable to our national history. In the reign of Elizabeth many of our best historians were printed, and of some of them more than one edition appeared. In the reign of Anne, Rymer's great collection of treatises and other important historical documents appeared. Matthew of Westminster was published in London in 1567, and again at Frankfort in 1601 in the same volume with Florence of Worcester, another writer of the same class, and a continuation of Matthew to the year 1377, the year of the death of Edward III.

MATTHIAS, Emperor. [HABSBURG, HOUSE OF; GERMANY, p. 190.]

MATTHISSON, **FREDERICK**, born at Hohendodeleben, near Magdeburg, in 1761, was a posthumous child, and brought up by his grandfather, a village pastor, until the age of fourteen, when he was sent to the school at Klosterbergen, and afterwards to the university of Halle, to study theology. His natural taste however led him to apply himself more to philology and general literature. Instead therefore of entering the church, he supported himself for some time as a private tutor at Altona, Heidelberg, and Mannheim, after which he resided for two years with his friend Bonstetten near the lake of Geneva. In 1794 he obtained the appointment of reader and travelling companion to the reigning princess of Anhalt-Dessau, and during the next seven or eight years visited Italy, the Tyrol, and part of Switzerland, relative to which countries his 'Briefe' and his 'Erinnerungen' furnish many interesting details, besides numerous sketches and anecdotes of distinguished literary persons and others with whom he became acquainted in the course of his tours. Although somewhat deficient in regard to simplicity of style, those works exhibit him to considerable advantage as a prose-writer; but it was as a lyric poet that he was the favourite of the German public, and will long continue to be admired for the happy delineation of external nature, and the touching melancholy and charm of sentiment which characterise his poems, besides their charms of style and versification. His 'Elegy in the Ruins of an old Castle' is hardly less popular than that of Gray is with us, being one of those productions which are of themselves sufficient to give the writer a lasting reputation. Matthiesson also performed a good office for the poetical literature of his country by his 'Lyrische Anthologie,' a collection in twenty volumes, published at Zürich, 1805-7, and containing select pieces and specimens from 202 lyric poets, commencing with Weckherlin, Zingref, Opitz, and other earlier poets, and terminating with Tiedge. These volumes may be considered as a gallery where the specimens of the different masters are arranged chronologically, and exhibit the characteristic qualities of each. Matthiesson died at Wörlitz, near Dessau, March 12, 1831.

MATTINS (from the Italian *mattina*, or the French *matin*, morning), strictly the first part in the daily service of the Romish church. Matins or mattins however were divided into two parts, which were originally distinct offices and hours; namely, the *nocturn* and *matin lauds*. The *nocturns* or vigils were derived from the earliest period of Christianity. We learn from Pliny the younger, as well as from Justin Martyr, Tertullian, and various writers of the first three centuries, that the Christians in those times of persecution held their assemblies in the night, in order to avoid detection. On these occasions they celebrated the memory of Christ's death in the holy mysteries. When persecution had intermitted and finally ceased, although the Christians were able to celebrate all their rites, and did administer the sacrament in the day-time, yet a custom which had commenced from necessity was retained from devotion and choice; and nocturnal assemblies for the worship of God in psalmody and reading still continued. The monastic orders, which, in the fourth century, arose under Pachomius, Anthony, Basil, and others, in Egypt, Pontus, and Syria, tended to preserve this custom of nocturnal vigils; and in the following centuries we find, from the testimony of Cassianus, Augustine, and others, that the same custom remained in most parts of the East and West. In the sixth century Benedict, the great founder of monastic societies in the West, prescribed the same in his Rule; and nocturnal assemblies were common about that time, especially in monasteries. The *lauds*, or more properly *matin lauds*, followed next after the nocturns, and were supposed to begin with day-break. We find allusions in the writings of Cyprian, and all the subsequent fathers, to the

morning as an hour of prayer; but whether there was in the third century any assembly of the church for the purpose of public morning worship is uncertain. However, about the end of the third or beginning of the fourth century there was public worship at this hour, as we learn from the 'Apostolical Constitutions,' where we have the order of the service. (Bingham's *Antiquities of the Christian Church*, b. xiii.; Palmer's *Origines Liturgicæ*, 8vo., Oxford, 1832, vol. i., p. 201-3; *Apostol. Constit.*, l. viii., c. 38.)

MATTO GROSSO. [BRAZIL.]

MATU'TA, the name of a genus of brachyurous crustaceans. [OXYSTOMES.]

MATY, **MATTHEW**, M.D., the son of Paul Henry Maty, a Protestant clergyman, was born in Holland in 1718, at Montfort near Utrecht, and was originally intended for the church; but in consequence of some mortifications which his father received from the synod on account of particular theological sentiments, his thoughts, when he grew up, were turned to physic. He took a degree at Leyden; and in 1740 came to settle in England, his father being determined to quit Holland for ever. His earliest patron in England appears to have been Lord Chesterfield. In 1750 he began to publish, in French, an account of the productions of the English press, which he printed at the Hague, under the name of 'Journal Britannique;' a publication which Gibbon praised, as exhibiting a candid and pleasing view of the state of literature in England for the space of six years, from January 1750, to December 1755. It answered its intention, and introduced Dr. Maty to the most eminent literary persons of the country. In 1756, as soon as the establishment of the British Museum was completed, he was appointed one of the first under-librarians of that institution. In 1758 he became a fellow, and in 1765, upon the resignation of Dr. Birch, was chosen Secretary of the Royal Society. In 1772, upon the death of Dr. Gouin Knight, Dr. Maty, by his majesty's appointment, became principal librarian of the British Museum. He died of a lingering disorder, August 2, 1776. His body being opened, the appearances which presented themselves were considered so singular that they were described before the Royal Society by Dr. Hunter, whose account of them was inserted in vol. lxxvii. of the 'Philosophical Transactions.' Dr. Maty was an early and active advocate for inoculation; and when a doubt was entertained that a person might have the smallpox, after inoculation, a second time, he tried it upon himself, unknown to his family. Besides various smaller pieces, he published,—1, 'Mémoire sur la Vie et sur les Ecrits de M. Ab. de Moivre,' 12mo., Haye; 2, 'Authentic Memoirs of the Life of Richard Mead, M.D.,' 8vo., London, 1755. At the time of his death he had nearly finished the 'Memoirs of the Earl of Chesterfield,' which were completed by his son-in-law Mr. Justamond, and prefixed to that nobleman's 'Miscellaneous Works,' 2 vols. 4to., 1777. Dr. Maty was Lord Chesterfield's executor. (Nichols's *Anecd. of Bowyer*; Gibbon's *Memoirs*, vol. i., p. 87; *Biographie Universelle*, tom., xxvii., p. 485-487.)

MAUBEUGE. [NORD.]

MAULE'ON. [PYRENEES, BASSES.]

MAUNDY THURSDAY, the Thursday preceding Easter, on which the king or queen distributes alms to a certain number of poor persons at Whitehall; so named from the *maunds*, or baskets, in which the gifts were formerly contained. It was also called Shere Thursday, as we read in the 'Festival' of 1511; because antiently 'people would that day shere theyr hedes and clypp theyr beides, and so make them honest agenst Easter-day.'

The following was the ceremonial of the maundy as practised in 1731. 'Thursday, April 15th, being Maundy Thursday, there was distributed at the Banqueting House, Whitehall, to forty-eight poor men and forty-eight poor women (the king's age, forty-eight), boiled beef and shoulders of mutton, and small bowls of ale, which is called dinner; after that, large wooden platters of fish and loaves, viz. undressed, one large old ling, and one large dried cod; twelve red herrings and twelve white herrings; and four half-quartern loaves. Each person had one platter of this provision; after which was distributed to them shoes, stockings, linen and woollen cloth, and leathern bags, with one-penny, two-penny, three-penny, and four-penny pieces of silver, and shillings; to each about four pounds in value. His grace the lord archbishop of York, lord high almoner performed the annual ceremony of washing the feet of a certain number of poor in the royal chapel, Whitehall, which

was formerly done by the kings themselves, in imitation of Our Saviour's pattern of humility.'

James II. was the last of our kings who performed this ceremony of washing the feet in person. In 'Le Guide de Londres pour les Étrangers, recueilli et composé par F. Colsoni,' 8vo., Lond., 1693, p. 33, we read, 'Le Jeudy Saint, le Roy, selon un fort ancienne coutume, lavo les pieds à tout autant de vieillards qu'il a d'années; et la Reine de meme à autant de vieilles femmes qu'elle a d'années.' The third edition of this work, 8vo., p. 43, adds, 'Mais le Roy (G. III. (Guillaume III.)), a laissé l'intendance de cette cérémonie à son grand Aumonier ou un Evêque du Royaume.'

The 'Times' newspaper of April 16th, 1838, records the change in this ceremony as it stands at present. 'The queen's royal alms were distributed on Saturday by Mr. Hanby, at the almonry office, to the maundy men and women placed on the supernumerary lists, owing to the difference of the ages between the late king and her present Majesty. Both men and women received 2l. 10s., and nineteen silver pennies (being the age of the queen). To the men, woollen and linen clothing, shoes, and stockings were given; and to the women, in lieu of clothing, 1l. 15s. each. The maundy men and women also received 1l. 10s., a commutation instead of the provisions heretofore distributed.'

The custom of the maundy is of considerable antiquity. Augustine, according to Du Cange, is first quoted for it. In England at least it was not entirely confined to royalty. In the earl of Northumberland's 'Household Book,' begun in 1512, fol. 354, we have an enumeration of 'Al maner of things yerly yeven by my lorde of his maundy, ande my laidis, and his lordshippi's childeren.'

Dr. E. D. Clarke, in his 'Travels in Russia,' 4to., Cambr. 1810, vol. i., p. 55, gives an account of the ceremonial of washing the feet of the apostles, as it is called, on this day at Moscow. 'This,' he says, 'we also witnessed. The priests appeared in their most gorgeous apparel. Twelve monks, designed to represent the twelve apostles, were placed in a semicircle before the archbishop. The ceremony is performed in the cathedral, which is crowded with spectators. The archbishop performing all, and much more than is related of our Saviour in the 13th chapter of St. John, takes off his robes, girds up his loins with a towel, and proceeds to wash the feet of them all until he comes to the representative of St. Peter, who rises, and the same interlocation takes place as between our Saviour and that apostle.'

(Nares's *Glossary*, v. 'Maund'; Brand's *Popular Antiq.*, 4to. edit., vol. i., p. 124-128; *Gent. Mag.*, vol. i., p. 172; Fosbrooke's *Encyclopædia of Antiquities*, p. 702.)

MAUPERTUIS, PIERRE-LOUIS MAREAU DE, was born at St. Malo, 17th July, 1698. Upon quitting the army, in which he held the rank of captain of dragoons, he applied himself assiduously to the study of the mathematics and astronomy, partly under the instruction of M. Nicole. In 1723 he was admitted a member of the Royal Academy of Paris, and in 1727 a member of the Royal Society of London. At this time the error in the measurement of the arc of the meridian conducted by Dominic and James Cassini had not been detected. It is well known that the result of this survey was directly at variance with the conclusion to which Newton had arrived relative to the figure of the earth: and although several of the geometricians of the day were of opinion that the comparison of degrees in latitudes so nearly contiguous (for the measured arc consisted of two conterminous portions, the difference of the mean latitudes of which was little more than 4°) could not be considered decisive, inasmuch as the errors incidental to the survey could not be supposed to be confined within such narrow limits as the small difference of length which the survey was employed to detect; still it afforded to others, who were interested in refuting the Newtonian theory, plausible grounds for disputing the oblate figure of the earth, to which that theory had led. To set the question at rest, Bouguer and La Condamine were sent to Peru; and during their absence Maupertuis, in company with Clairaut, Camus, Lemonnier, and Outhier, were deputed by the Academy to measure an arc of the meridian in Lapland. They were afterwards joined by the Swedish astronomer Celsius, who brought with him from London instruments made by Graham, of a very superior construction to any then in use. The party reached the gulf of Bothnia in July, 1736, intending to fix their trigonometrical stations upon the islands of the gulf; but upon examination, they found the valley of the river Tornea

more eligible for the purpose, and, in December following, commenced measuring a base of 7407 toises upon the frozen surface of that river. An account of this survey was published by Maupertuis in 1738: 'La Figure de la Terre,' 8vo., Paris, 1738. The result was that the difference of latitude of the extreme stations, namely, the town of Tornea and the mountain Kittis, was 57' 29".6, and that the length of the corresponding arc was 55,023 toises, from which it followed that a degree of the meridian in 66° N. lat. exceeded a degree in the latitude of Paris by 512 toises, and consequently tended to prove that the earth's figure was that of an oblate spheroid. The survey was repeated in the years 1801-2-3, by Svanberg, whose result differed from that of Maupertuis by 226 toises.

Maupertuis was one of the first among his countrymen who defended the Newtonian theory against the attacks of Descartes, and when his opinion was confirmed by the result of his survey, he became an open and strenuous opposer of the Cartesian philosophy. When Frederic II. was about to re-organise the academy of Berlin, he offered the presidency to Maupertuis, who, tired of his stay in Paris, where, says M. Delambre, the reputation of many had a tendency to eclipse his own, eagerly assented to so honourable a proposition. But his residence at the court of Prussia, which dates from 1745, seems to have been chiefly occupied in cultivating the good graces of Frederic, and he showed little interest as to scientific research except such as had reference to his survey in Sweden. His vanity on this point was conspicuous. In the portrait which he had painted of himself he is represented in the act of compressing the poles of the earth. He died at Basle, 27th July, 1759, at the house of two of the sons of John Bernoulli, with whom he had always been on terms of friendship. His latter years were embittered by a dispute with Koenig, professor of mathematics at the Hague and foreign associate of the academy of Berlin, respecting a mechanical principle of considerable importance, which Maupertuis appears to have been the first to promulgate, and from which he deduced the laws of the reflexion and refraction of light, and those to which the collision of bodies are subjected, but of which he was unable to give any general demonstration. This principle, which he designated 'the principle of least action,' he enunciated in terms identical with those employed at the present time (see his *Essai de Cosmologie*, Leyden, 1751, p. 70), although he probably attached to them a somewhat different signification. Koenig endeavoured to show, first, that the same principle had been previously advanced by Leibnitz; secondly, that it was not true. The academy of Berlin, to whose arbitration the dispute was referred, decided in favour of Maupertuis, and ordered the name of Koenig to be erased from their list of associates; but even this decision, added to the support of the celebrated Euler, seemed inadequate to compensate Maupertuis for the raillery of Voltaire, who, although totally incompetent to judge on the scientific merits of the case, had taken the part of Koenig, and published his satirical piece entitled 'Diatriba du Docteur Akakia, Médecin du Pape,' wherein he was too successful in turning into ridicule both Maupertuis and his 'principle.' Frederic, who disliked Maupertuis, laughed at the satire, but ordered it to be burnt by the common executioner, which led to Voltaire's asking and obtaining permission to leave Berlin. (*Vie de Voltaire*, par Condorcet.) The following list of the published works of Maupertuis is given in Quérard's 'Dictionnaire Bibliographique':—

'Anecdotes, physical and moral,' 12mo., no date. 'Nautical Astronomy, or Elements of Astronomy, alike applicable to a fixed and moveable Observatory,' 8vo., Paris, 1743 or 1751; Lyon, 1756. 'Memoirs read before the royal academies of France and Prussia,' 16mo., Dresden, 1753. 'Mémor on the Moon's Parallax,' 1755. 'Discourse on the different Forms of the Stars, with an Exposition of the Systems of Descartes and Newton,' 8vo., Paris, 1732 and 1742. 'A Latin inaugural and metaphysical Dissertation on the System of Nature,' 12mo., 1751. The same in French, Berlin, 1754. 'Dissertation on the White Negro,' 8vo., 1744. 'Elements of Geography,' 8vo., Paris, 1740. 'Eloge of Montesquieu,' 8vo., 1755. 'Essay on Cosmology,' 8vo., Berlin, 1750. 'Essay on Moral Philosophy,' Berlin, 1749; and London, 1750. 'Disinterested Examination of the different Undertakings for determining the Figure of the Earth,' Oldenburg, 1738; and Amsterdam, 1741. 'Examination of the three Dissertations published by M. Des-

aguiers on the Figure of the Earth,' Oldenb., 1738 (this book, by some attributed to Maupertuis, is supposed to have been written by the Count de Bièvre). 'The Figure of the Earth, as determined by the Observations of MM. Maupertuis, Clairaut, Camus, Le Monnier, Outhier, Celsius, &c., near the Polar Circle,' Paris, 8vo., 1738. 'Letter to Madame de Vertillac,' Paris, —. 'Letter to Euler,' —. 'Letter of an English Clockmaker to an Astronomer of Pekin,' 12mo., 1740 (a humorous satire against MM. de Cassini on the subject of the measurement of the meridian). 'Letter upon a Comet,' Paris, 1742. 'Letter on the Progress of the Sciences,' Berlin, 1752. 'The Measurement of a Degree of the Meridian between Paris and Amiens, determined by Picart, with the Observations of MM. Maupertuis, Clairaut, Camus, and Le Monnier,' 8vo., 1740. 'Miscellaneous Works,' 12mo., Amsterd., 1744. 'Philosophical Reflections on the Origin of Language and the Signification of Words,' 12mo. 'A Method of superseding the action of the Wind,' 1753. 'Venus physique,' 1745 and 1777. The works of Maupertuis were collected and published at Dresden, in 1752, 4to.; and at Lyon, in 1754 and 1768, in 4 vols. 8vo. Among his memoirs in the Transactions of the French Institute, his 'Balistic Arithmetic,' 1731, and an elegant Commentary upon the 12th section of the first book of the 'Principia,' 1732, deserve particular mention.

(*Life of Maupertuis*, by Delambre, in the *Biographie Universelle*; Montucla, *Histoire des Mathématiques*, &c.)

MAUR, ST. There appear to have been two persons of this name: one a disciple of St. Benedict, who is mentioned in St. Gregory's 'Dialogues,' and who is said to have died in 581; the other, abbot of Glanfeuil, who lived till 640, and was a monk of the order of St. Coloman, and not of St. Benedict. Of the former of these a Life is extant in the great work of the Bollandists. His day was the 15th of January.

(Moreri, *Diction. Historique*, tom. vii., fol., Par., 1759, p. 357; Alban Butler's *Lives of the Saints*, 8vo., Dubl. 1779, vol. 1., p. 169.)

MAUR, ST., CONGREGATION OF, a celebrated society of Benedictines in France, who professed to follow the primitive rule of that order. It was first established in 1618. Pope Gregory XV., at the instance of Louis XIII., gave it his approval by his brief dated 17th May, 1621; and Urban VIII. granted it new privileges by a bull dated 21st January, 1627. The report of the sanctity of this congregation induced several bishops, abbots, and monks to submit their monasteries to the direction of its superior, so that the congregation at last became divided into six provinces, of which each contained about twenty religious houses. The most considerable were, St. Denys, St. Germain-des-Prés, St. Remi at Rheims, Marmonstier, St. Pierre de Corbie, Fleury or St. Benoit sur Loire, Fescamp, and the Trinité de Vendôme. The monks, beside the rule of St. Benedict, had other particular statutes and constitutions, and were governed by a general superior, assistants, and visitors, who held a general chapter every three years at Marmonstier. Those who have any acquaintance with the history and progress of learning in Europe will readily acknowledge the advantages which letters have derived from this famous congregation, whose researches took in the whole circle of sciences, philosophy excepted. Among its more eminent members in the seventeenth century may be enumerated Hugh Menard, Luc d'Acheri, Jean Mabillon, Thierri Ruinart, and Bernard de Montfaucon. Moreri gives a list of the general-superiors of this congregation from 1630 to 1756.

(Moreri, *Diction. Historique*, tom. vii., pp. 357, 358; *Histoire Littéraire de la Congregation de Saint Maur*, 4to., Bruxelles, 1770, by Dom Tassin.)

MAURA, SANTA. [SANTA MAURA.]

MAURIAC. [CANTAL.]

MAURICE OF NASSAU. [NASSAU, HOUSE OF.]

MAURITANIA or MAURETANIA, which derived its name from its inhabitants Mauri or Maurusii (*Μαυροί*), was bounded on the west by the Atlantic, on the north by the Mediterranean, on the south by the Gætuli, and on the east by Numidia, thus corresponding to the northern part of Morocco and the western part of Algiers. The country of the Mauri was originally separated from that of the Musgæsyli by the Molocath (Strabo, p. 827, Casaubon) or Mulucha (Plin., v. 1), the modern *Mulwia* or *Mohalou*; but the Roman province of Mauritania included the country inhabited by both these people

Before the war with Jugurtha, the Romans had little or no knowledge of Mauritania; of which Bocchus was at that time the ruler. (Sallust, *Bell. Jugurth.*, c. 19.) Mauritania was afterwards given by Augustus to Juba II., his paternal kingdom of Numidia having been erected into a Roman province. [JUBA.] Juba died about A.D. 17, and was succeeded by his son Ptolemaus, who was put to death by Caligula. Mauritania was shortly afterwards divided into two provinces by Claudius (A.D. 43); which were called respectively Mauritania Tingitana and Mauritania Cæsariensis. (Dion Cassius, ix., p. 771, Stephan.) Tingitana, the western province, which derived its name from Tingis (*Tangier*), was divided from the other province Cæsariensis by the Molocath; and Cæsariensis was separated from Numidia by the Aimpasgas (*Wadi al-Kebir*). Mauritania Cæsariensis was subsequently subdivided into two provinces: the western part retained the name of Cæsariensis, but the eastern was called Sitifiensis, from Sitifi (*Setif*), a town on the borders of Numidia.

Mauritania contained many towns of considerable importance under the Roman empire. Of these, the principal in Mauritania Tingitana were, Ru-adir (*Melillah*), a seaport and a Roman colony, west of the Molocath; Tingis (*Tangier*), at the entrance of the Straits of Gibraltar, which received especial marks of favour from Augustus Cæsar (Dion, xlviii., p. 439), and became a Roman colony under Claudius (Pliny, v. 1); Zilis or Zelis (*Arzilla*), made a Roman colony by Augustus under the name of Julia Constantia Zilis, and placed under the same jurisdiction as the province of Bætica in Spain (Plin., v. 1): it was situated a little to the south of C. Spartel, which is called Cotes by Strabo (p. 825, Casaubon), and Ampelusia by Mela (i. 5); Lixus, Laxus, or Langa (*Al Araish*), a Roman colony, 32 Roman miles south of Zilis, situated on a river of the same name, which must not be confounded with the great river Laxus mentioned in Hanno's 'Periplus,' which is probably the same as the modern St. Cyprian [HANNO'S PERIPLUS]; Banasa, a Roman colony, 50 Roman miles south of Laxus, situated on the Subur (*Sebou*); and, 50 miles south of the Subur, Sala (*Salee* or *Sla*), of which there are extensive ruins.

The chief towns in Mauritania Cæsariensis were: Salda, Sarda, or Salde (*Bonjourah*), a seaport and a Roman colony, which divided the kingdom of Juba from the province of Numidia (Strabo, p. 831); Julia Cæsarea (*Zershal*, see Shaw, p. 40, 41, ed. of 1738), situated on the coast west of Salda, a Roman colony, which was originally called Iol (Strabo, p. 831; Pliny, v. 1); Siga (*Takumbrit*), which Pliny (v. 1) erroneously places opposite Malaga in Spain; and in the interior, south-west of Cirta, the important town of Sitifi (*Setif*), a Roman colony.

The physical features, &c. of Mauritania are described under articles the ALGIERS and MAROCCO. The best account of the eastern part of Mauritania is in Shaw's *Travels*.

MAURITIUS, the Island of, called also ISLE DE FRANCE, is situated in the Indian Ocean, between 19° 45' and 20° 33' S. lat., and between 56° and 57° E. long. From north to south, from Cap Malheureux to the Bay of Lemon-trees (citronniers), its length is about 36 miles: and its extreme width from Point du Diable to the northern extremity of the Plaine aux Sables (Plain of Sand) is nearly 27 miles, though in general it is little more than 15 miles. The circuit is about 124 miles. The area is about 700 square miles, or nearly the extent of the county of Worcester.

The island is surrounded by a coral reef, generally running parallel to the shores, at the distance of one or two furlongs, and mostly dry at low water. In this reef occur eleven breaks, by the greater number of which vessels of considerable burden may approach the island. The water between the reef and the shores, being less agitated than the open sea, affords facilities of communication between the places along the coast, which is the more important as the shore in several places rises with a steep ascent and to a considerable elevation close to the water-edge. This is especially the case along the western coast. Along the eastern coast the surface is pretty level from Port Souillac to Grand Port, and from the latter to Port Louis, except in the immediate neighbourhood of both places. The interior of the island consists of a great number of lofty hills, which however are mostly isolated, except between Cape Brabant and Port Souillac, where they constitute a small chain, and another chain runs from the mountain of Peter Botte to Cannonière Point. Some of the hills attain a considerable elevation, especially the Brabant mountains, near Cape

Brabant, and the Bamboo ridge, near Grand Port, which probably rise to 3000 feet above the sea-level. The origin of the island is without doubt volcanic, as shown by the irregularities of the surface, the presence of lava, pumice, and other volcanic productions. In the mountains at the back of Port Souillac and Grand Port is a small lake, which is considered to be an extinct crater. The ground is generally covered with loose rocks, from the size of a man's fist to pieces weighing a ton or more, and they are full of holes. The soil is shallow, and by no means distinguished by fertility, which is mainly to be attributed to its dryness and the frequent want of rain. It consists principally of a lumpy reddish mould, evidently impregnated with oxide of iron, and crumbling to dust in the hand.

The rainy season lasts from November to March or April. The rain comes down in torrents for several hours continually, and is accompanied with heavy gusts of wind: thunder and lightning are frequent. Hurricanes as terrific as those of the West Indies sometimes visit the island during this season. They do not occur with any regularity; but five years rarely elapse between their visitations. During this season the wind frequently changes, and sometimes makes the tour of the horizon. In the dry season the wind generally blows from the south-east. It is strong during the day, but calm in the night. During the months of June, July, and August, showers are frequent, but they last only a short time. The island is traversed by numerous watercourses, which run off from the centre towards all points of the compass; but they are only filled with water during the rainy season, when they form numerous cataracts: during the dry season the water is speedily evaporated by the heat of the sun. The mean annual heat is about 76° Fahrenheit. The fall of rain from the 1st of October, 1831, to the 30th of September, 1832, was 38 inches. We have not been able to obtain any further account of the quantity of rain. The highest observed temperature in the year above mentioned was 87°, and the lowest 60° of Fahr.

This island was formerly covered with woods, and even now a considerable part of the native forest is allowed to remain for ornament round the plantations: the hilly districts in the interior are covered with trees. There is however no timber fit for ship-building. The ebony wood is of inferior quality, but the iron-wood and red-wood are valuable. The sago and cocoa-nut palms are common, as also tamarind-trees, mangroves, and bamboos. Yams, cassava or manioc, which was brought from South America, and Indian corn, are cultivated as articles of food; as well as plantains, bananas, and melons, with several European vegetables, as spinach, asparagus, artichokes, cabbages, and peas. Wheat and rice are raised in small quantities, and both articles are imported, the former from the Cape and the second from Madagascar. There are also mangoes, shaddock, and pine-apples. Oranges, grapes, peaches, and apples are of inferior quality.

The French introduced the spice-trees of the Indian islands, but none of them succeeded, except the clove; even the pepper-vine remained barren. They also cultivated sugar, indigo, coffee, and cotton. But since the British have been in possession of the island, all these branches of agriculture have been nearly abandoned, with the exception of sugar. The cultivation of sugar has rapidly increased; in 1830 more than 720,000 hundredweights were exported.

Horses are few, and seldom bred in the island. Mules and asses are more numerous, and principally used for the saddle. Black cattle are scarce, on account of the want of good pasture, the pasture-grounds being few and bad. Cattle are imported in great numbers from Madagascar; goats and sheep are numerous; hogs abound, and form a material part of the food of the people. The forests contain hogs and deer, neither of which are probably indigenous. Fish is abundant along the coast: the turtle has almost wholly disappeared, but all the small sandy islets situated to the north-west of Mauritius afford them in abundance, and they are large and fine. Rats, locusts, and ants are destructive to the plantations and storehouses.

The population amounts to about 100,000, of which number about 76,000 are negro slaves brought from Madagascar and the eastern coast of Africa. The number of coloured free people exceeds 15,000, and among them are Malays, fishermen from the coast of Malabar, Lascars, and Chinese. The Chinese have lately been brought over, and employed in the cultivation of the sugar-cane, instead of

the negro slaves. The number of whites amounts to about 9000 individuals: the greater part of them are descendants of French families, and speak the French language.

Port Louis, the capital and only town of the island, is situated near the north-western extremity, on a small bay called Port North-West, or Port Louis. This bay is a narrow inlet of the sea, somewhat more than a mile long, and about five hundred yards broad. A reef runs out from its mouth, passing close to a small island, called Tonnelier Island, a coral rock, near which vessels usually anchor, as the wind continually blows out of the harbour. The harbour is sufficiently capacious for a dozen men-of-war and fifty sail of merchant ships, and during the fine season perfectly safe. At its extreme south-western corner the town is built. The streets are straight but not paved; the principal street runs parallel to the shores of the bay. The houses are all built of wood, with only one floor. The town contains 26,000 inhabitants, of which number 15,700 are slaves, 4000 whites, and the remainder coloured free people. One of the suburbs contains about 3000 Malabar fishermen, and another about 7500 free negroes. There is a library containing more than 60,000 volumes, mostly French books, a good botanical garden, and some docks for the repair of vessels.

On the windward coast of the island is Port Grand, also called Port South-East, which is large, but its entrance is very difficult, being narrowed by several shoals. It can only be entered and left with a fair wind, as it is impossible to tack. It is not much frequented.

The commercial relations of Mauritius extend to Batavia, Bombay, Surat, Muscat, the Persian and Arabian Gulfs, the western coast of Africa, the Cape, and Madagascar, but a considerable portion of its produce comes to England. Besides sugar, small quantities of indigo, coffee, cloves, and some woods are exported. The island receives from England and India silk and cotton goods, and from England besides, cloth, wine, oil, hats, iron, and steel utensils, with some smaller articles. Madagascar supplies the Mauritius with cattle and rice, and receives in return manufactured goods. Arabia and Persia are supplied with sugar from the Mauritius, and send in return dry fruits and some smaller articles.

Mauritius, with the neighbouring island of Bourbon, was discovered by the Portuguese under the command of Mascarenhas in 1505, and the whole group was called the Mascarenhas Islands; but though the Portuguese took possession of Mauritius in 1545, they apparently formed no settlement on it. The Dutch surveyed it in 1598, and called it Mauritius, in honour of Maurice, stadtholder of the republic of the Netherlands. They did not however settle here till they had formed an establishment at the Cape in 1640, about which time they fixed themselves on the shores of Port South-East. From unknown reasons they abandoned the island in 1708. Between this year and 1715 it was only inhabited by a few negroes who had been brought there by the Dutch as slaves, and had run away from their masters and concealed themselves in the mountain forests. In 1715 the French took possession of the island, formed a settlement at Port North-West, and called the island Isle de France. They remained in the undisturbed possession of it to the year 1810, when it was taken from them by the British, who since the peace of 1814 have retained it in their possession.

(*A Voyage to the Island of Mauritius*, by a French Officer; *Tombo's Voyage aux Indes Orientales*; *Prior's Narrative of a Voyage in the Indian Seas*; *Grant's History of Mauritius*.)

MAURO-LICO, or MARULLO, FRANCIS, abbot of Messina, was born at that place, September 16, 1494, and died there, July 21, 1575. Several accounts, which do not conceal the age which he attained, state that he was prematurely sacrificed to excess of study. His life was written by his nephew of the same name, and was published at Messina in 1613; we have not seen this work, but it is much used, and freely quoted, in the Abbé Domenico Scina's 'Elogio,' Palermo, 1808, which contains a full but flattered account of the life and writings in question. Maurolico taught mathematics publicly at Messina, and lived in habits of close friendship with Cardinal Bembo. These, and his being obliged, much against his will, to suppress a part of his dissertation on comets, on account of the offence which some passages gave to certain Venetian noblemen, are the only circumstances of his personal life which are worth recording.

The printed works of Maurolico are numerous, and those which he wrote still more so; a list of all (but without titles or dates for the printed works) is given by the Abbé Seina. Among the former must be mentioned an edition of Autolycus with commentaries, Messina, 1558, folio; of ARCHIMEDES, 1670 (misprinted 1570 in the article cited) and 1681 (or 1685?): the Phenomena of Euclid, 1588, and an edition of Theodosius and Menelaus in the same year, which contains a table of secants, being the first introduction of these lines; 'Opuscula,' printed at Venice, 1575, containing treatises on the sphere, the calendar, astronomical instruments, gnomonics, music, and arithmetic; treatise on Cosmography, 1543. Other works have been stated as printed, but we have only inserted those which have good authority.

Maurolico will be remembered by his geometrical writings, particularly his manner of treating the conic sections, by his optical theorems, and by his arithmetical works; but the interest which attaches to his writings connects them rather with the general history of the science than with his own biography, as there are no very prominent discoveries to record. In his arithmetic he proceeds upon geometrical principles, as his eulogist states (and with confirmatory descriptions and citations), but at the same time with an attempt to generalize operations into rules, and to present them in a form closely approaching to the modern algebra, to the spirit of which they approach, without the language. It is to be remembered that before the time of Vieta the method of expressing general formulæ, which now constitutes the foundation of algebraical language, did not exist; and it seems to us, from such parts of Maurolico's writings as we have seen cited (the works themselves are very scarce), that the transition from the arithmetic of Euclid to that of Maurolico is an approach to algebra of a character which deserves more attention than it has met with from historians. These writers, so far as algebra is concerned, do not even mention the name of Maurolico, a circumstance which must be explained probably by the latter not being in the line of investigation of Cardan, Tartaglia, and those who lie in the direct track between the Hindu algebra and that of Vieta. Nevertheless the propositions of Maurolico on the summation of series, and the methods by which they were deduced, form a very curious step in the progress of arithmetical inquiry.

M. Chasles, in his lately published work on the history of geometry [GEOMETRY, page 156] carries his opinion of Maurolico as an algebraist, to a startling degree of novelty. 'Analysis is infinitely indebted to this geometer, who nevertheless is very little cited on the subject. It is he who first introduced the use of letters instead of numbers, and who gave the first rules of the algorithm of algebra.' Not having examined Maurolico ourselves, we can only say that neither Wolff, nor Cossali, nor the Abbé Seina, could find this out; the last expressly speaks of Maurolico as having 'the spirit of algebra, without the language.' Perhaps however the assertion of M. Chasles may provoke some attention to the subject, and excite an inquiry into the extent of the claim which Maurolico really has to be considered as one of the founders of algebra; an inquiry which, terminate how it may, has been yet hardly begun.

MAURUS TARENTIANUS, a Latin grammarian, who is said to have been born at Carthage. The time in which he lived is uncertain. Vossius supposes him to have been the same Terentianus who is addressed by Martial as the prefect of Syene in Egypt (*Epigram*, i. 87); and he at all events lived during or before the time of St. Augustine, since he is mentioned by the latter in terms of the highest respect. (*De Civitate Dei*, vi. 2; *De Utilitate Credendi*, c. 17)

The only work of Maurus which has come down to us is entitled 'De Litteris, Syllabis, Pedibus, et Metris Carmen.' It is included in the 'Grammatici Veteres,' edited by Putschius, Hanover, 1605; and has been also edited by D. J. V. Lennep, Leyden, 1825, and by Lachmann, Leipzig, 1836.

MAUSOLEUM is now used as a general term applied to a sepulchral chapel or edifice erected for the reception of a monument; but it originally designated the magnificent structure raised by Artemisia as the tomb of her husband Mausolus, king of Caria, at Halicarnassus, B.C. 352. Of this monument, once reckoned among the wonders of the world, no remains now exist; but from Pliny's description (xxxvi., 5) it appears to have been nearly square in its plan, measuring 113 feet on its sides, and 93 on each of its ends

or fronts, and to have been decorated with a peristyle of thirty-six columns (supposed by Hardouin to have been 60 feet high, or upwards), above which the structure was carried up in a pyramidal form, and surmounted at its apex by a marble quadriga executed by Pythis, who, according to Vitruvius, was joint architect with Satyrus in the building. It was further decorated with sculptures and reliefs by Scopas, Bryaxis, Timotheus, and Leochares. The entire height was 140 feet.

The mausoleum erected at Babylon by Alexander the Great, in honour of Hephæstion, appears to have been still more magnificent, and somewhat extravagant in its decorations, as far as can be gathered from the account given of it by Diodorus (xvii. 115). It was adorned below by the gilded rostra, or beaks, of two hundred and forty ships, and every successive tier or story was enriched with a profusion of sculpture, representing various animals, fighting centaurs, and other figures, all of which were gilt; and on the summit were statues of sirens, made hollow, in order that the singers who chanted the funeral dirge might be concealed within them.

Those of Augustus and Hadrian at Rome were structures of great magnitude and grandeur, and resembled each other in being circular in plan. The first stood in the Campus Martius, where remains of it yet exist in the two concentric circles forming the first and second stories of the building, and the vaulted chambers between, which supported the first or lowest terrace. Of these terraces there were three; consequently four stages in the building, gradually decreasing in diameter, the uppermost of which was crowned by a colossal statue of the emperor. The terraces themselves were planted with trees. From traces of something of the kind that yet remain, it is conjectured that there was originally an advanced portico attached to the building in the same manner as that of the Pantheon, though considerably smaller in proportion to the rest of the plan, as it could not have been carried up higher than the first stage of the building. According to Hirt's representation of it, in his 'Baukunst bei den Alten,' it was a Corinthian hexastyle, advanced one intercolumn before the side-walls connecting it with the circular edifice behind it.

Hadrian's mausoleum, now converted into the Castello di St. Angelo, in which shape it is familiar to almost every one, is a work of most massive construction, and originally presented an unbroken circular mass of building, erected upon a larger square basement, lofty in itself, yet of moderate height in proportion to the superstructure, the latter being about twice as high as the former. This nearly solid rotunda, which was originally coated with white marble, had on its summit numerous fine statues, which were broken to pieces and the fragments hurled down by the soldiers of Belisarius upon the Goths, who attempted to take the building by storm. Neither are any remains now left of the uppermost stage of the edifice, which assumed the form of a circular peripteral temple, whose diameter was about one-third of the larger circle. According to tradition, its peristyle consisted of the twenty-four beautiful marble Corinthian columns which afterwards decorated the basilica of San Paolo fuori delle Mura (partially destroyed some few years ago by fire, but now nearly restored); and its tholus or dome was surmounted by a colossal pine-apple in bronze, now placed in the gardens of the Vatican.

Such places as Henry VII.'s Chapel and the Pantheon of the Escorial may also be considered as mausoleums; but the term is generally restricted to a detached edifice erected merely as a private burying-place or to contain tombs. There are several structures of the kind in the parks of our nobility; among the most remarkable is that at Castle Howard, the seat of the earl of Carlisle, and one of Hawksmoor's best works, a noble circular edifice in the Roman-Doric style, elevated upon a basement, and crowned by a dome: plans, sections, &c., of this structure have been beautifully engraved by Moses. The marquis of Rockingham's mausoleum by Carr is another ornamental structure of the kind, composed of three stories, Doric, Ionic, and Corinthian. We may also mention those at Cobham in Kent, and Brocklesby in Lincolnshire, by the late James Wyatt. The mausoleum of Louisa, queen of Prussia, at Charlottenburg near Berlin, has a Grecian-Doric portico, but is not so remarkable as a building as for containing the sarcophagus on which is the recumbent figure of that princess, the chef d'œuvre of Rauch's chisel.

MAWES, ST. [CORNWALL.]

MAWMOISINE, or MALVOISINE, WILLIAM DE, was bred in France, and has been thought by some to have been a native Frenchman. He afterwards came to Scotland, where he was made one of the *clerici regis*, and archdeacon of St. Andrew's, in which latter capacity he was present at the baptism of Prince Alexander, afterwards King Alexander II. He was made chancellor of Scotland 6 Id. September, 1199, about which time also he was elected bishop of Glasgow, and consecrated the following year by special precept from the pope. (Fordun, viii. 61.) In the year 1202 he was translated to the see of St. Andrew's, when he seems to have resigned the office of chancellor. In September, 1208, he dedicated a new cemetery at Dryburgh Abbey. (2 Chalm., *Caled.*, 339.) He afterwards made a visit to the Continent; and having returned, we find him and the bishop of Glasgow, in 1211, possessed of legatine powers from Rome, and assembling at Perth a great council of the clergy and people, to press upon the nation the pope's will and command that an expedition be undertaken to the Holy Land. (Fordun.) In 1214 he attended the coronation of King Alexander II. (Id., ix. 1), and is said to have set the crown upon the king's head. The next year he went with the bishops of Glasgow and Moray and the mitred abbot of Kelso to the Fourth Lateran Council, where the doctrines of Wycliffe were condemned, and seems to have remained abroad till 1218. From the Continent he brought with him into this country various orders of monks and mendicants, till then unknown here, and had convents of Black Friars erected at Aberdeen, Ayr, Berwick, Edinburgh, Elgin, Inverness, Montrose, Perth, and Stirling, and monasteries for the monks of Valliscaulium at Pluscardine, Beaucheu, and Ardehatten. He wrote lives of the popish saints Ninian and Kentigern. It was to him and in his time that Pope Innocent III. sent the decretal letters which we find in the 'Corpus Juris Canonici' (*Decret.*, Greg., b. iii., tit. 49, c. 6), to the king of Scots, and (b. iii., tit. 24, c. 9; b. iv., tit. 20, c. 6; and b. v., tit. 39, c. 28), to the bishop, archdeacon, and abbot of St. Andrew's, respectively.

But zeal for the church was by no means this prelate's only passion; for we find that on one occasion, noticed by Fordun (viii. 62), he deprived Dunfermline Abbey of the presentation to two churches, because the monks had failed to provide him wine for supper. Fordun adds that the monks had indeed supplied wine; but the bishop's own attendants had drunk it all up. It may be that the name of Malvoisine was originally but a mere soubriquet, from his malmsey bibbing propensity, as if it were 'William of the Malmsey-butt.'

He continued bishop of St. Andrew's till his death (Keith's *Bishops*), which happened on the 9th July, 1238 (3 Chalm., *Caled.*, 616); and he is remembered in a composition respecting tithes, anno 1297 (2 Connell, *On Tithes*, 413).

MAXE'NTIUS, MARCUS AURELIUS VALERIUS, son of Maximianus, the colleague of Diocletian in the empire, was living in obscurity when, after his father's abdication, and the elevation of Constantine to the rank of Cæsar, he became envious of the latter, and dissatisfied with the neglect of Galerius towards him. Accordingly he stirred up a revolt among the prætorian soldiers at Rome, and was proclaimed emperor, A.D. 306. Galerius, who was then in the East, sent orders to Severus Cæsar, who had the command of Italy, to march from Milan to Rome with all his forces, and put down the insurrection. In the mean time Maximianus, who lived in retirement in Campania, came to Rome, and was proclaimed emperor as colleague with his son, A.D. 307. Severus, on arriving with his troops near Rome, was deserted by most of his officers and soldiers, who had formerly served under Maximianus, and were still attached to their old general. Upon this he retired to Ravenna, which he soon after surrendered to Maximianus, on being promised his life and liberty; but Maximianus put him to death. Maximianus proceeded to Gaul to form an alliance with Constantine, leaving Maxentius at Rome. Galerius soon after arrived in Italy with an army; but not finding himself strong enough to attack Maxentius in Rome, and fearing the same fate as that of Severus, he made a precipitate retreat. Maximianus, returning to Rome, reigned for some months together with his son, but afterwards quarrelled with him, and took refuge with Galerius, who acknowledged him as emperor. There were then no less than six emperors,

Galerius, Maximianus, Constantine, Maxentius, Licinius, and Maximinus Daza. In the following year, 309, Maxentius was proclaimed consul at Rome, together with his son, M. Aurelius Romulus, who in the next year was accidentally drowned in the Tiber. Maxentius possessed Italy and Africa; but Africa revolted, and the soldiers proclaimed as emperor an adventurer of the name of Alexander, who reigned at Carthage for three years. In the year 311 Maxentius sent an expedition to Africa, defeated and killed Alexander, and burnt Carthage. Proud of this success, for which he had the honour of a triumph, Maxentius made great preparations to attack Constantine, with whom he had till then preserved the appearance of friendship. Constantine moved from Gaul into Italy, advanced to Rome, and defeated Maxentius, who was drowned in attempting to swim his horse across the Tiber, A.D. 312. [CONSTANTINUS, FLAVIUS VALERIUS.]

MA'XIMA AND MI'NIMA. These Latin words, which simply mean 'greatest' and 'least,' are used to imply, not the absolute greatest and least values of a varying quantity, but the values which it has at the moment when it ceases to increase and begins to decrease, or vice versa. Thus if it be said that the height of the barometer was a maximum at ten o'clock, it means that up to that hour the barometer rose, and then began to fall; in which case it would still be said to have been a maximum, even though it should afterwards rise, and stand at a greater height than at ten o'clock. Thus it is possible that there should be several maxima and minima in one day, and even that one of the minima should be greater than one of the maxima: that is, at one moment when the fall ceases and a rise begins, the barometer may then be higher than it was at another time when a rise had ceased and a fall begun.

The theory of maxima and minima is, mathematically speaking, very simple. It is obvious, from the definition of a differential coefficient, that if y be a function of x , and if x be increasing, then when y also increases, $\frac{dy}{dx}$ is positive;

and when y diminishes, $\frac{dy}{dx}$ is negative. If the words in-

crease and diminution have their full algebraical sense, this proposition is true whatever the sign of y may be. It follows that when increase ceases and diminution begins, $\frac{dy}{dx}$ changes from positive to negative, and when diminution ceases and increase begins, it changes from negative to positive. But as a quantity cannot change its sign without becoming either nothing or infinite; it follows, first, that y can only be a maximum when x has such a value that $\frac{dy}{dx}$ is nothing or infinite; secondly, that there is not then a maximum unless the latter changes from positive to negative, when x increases through that value; nor a minimum

unless the same differential coefficient changes from negative to positive, in the same case.

Thus when $y = a + x - x^2$, the differential coefficient of which is $1 - 2x$, we see that the latter changes sign when x changes from less than $\frac{1}{2}$ to greater than $\frac{1}{2}$; and the change of sign is from positive to negative. There is therefore a maximum when $x = \frac{1}{2}$, and this maximum is $a + \frac{1}{2} - \frac{1}{4}$, or $a + \frac{1}{4}$.

When $\frac{dy}{dx} = 0$ (which is by far the most common case), and there is a maximum, it changes sign from $+$ to $-$, or diminishes, algebraically speaking: therefore $\frac{d^2y}{dx^2}$ is negative. Similarly, when $\frac{dy}{dx} = 0$, and there is a minimum, $\frac{d^2y}{dx^2}$ is positive. But when $\frac{dy}{dx}$ is infinite, and there is a maximum or minimum, this additional rule does not apply.

Works on the differential calculus give the development of this theory and examples. We shall only here add one of the rules for determining the maximum or minimum when there are two distinct variables.

When z is a function both of x and y , two variables independent of one another, there may be a maximum or minimum when $\frac{dz}{dx}$ and $\frac{dz}{dy}$ are both nothing, both infinite, or one nothing and the other infinite. When they are both nothing, which is the only case in which this theory is of any practical application, it must be determined as follows, whether there is any maximum or minimum, and which it is. Find the values of x and y which make $\frac{dz}{dx} = 0$, $\frac{dz}{dy} = 0$, and with any pair of these values find the value of the expression

$$\left(\frac{d^2z}{dx dy} \right)^2 - \frac{d^2z}{dx^2} \cdot \frac{d^2z}{dy^2}$$

If this be negative, or nothing, there is a maximum or minimum; if it be positive, there is a mixture of the two which can only be satisfactorily explained by illustrations drawn from the theory of curved surfaces. When the expression is negative or nothing, there is a maximum if $\frac{d^2z}{dx^2}$

and $\frac{d^2z}{dy^2}$ be both negative, and a minimum if they be both positive.

The usual method of establishing all the preceding formulæ, namely, by the application of Taylor's theorem, applies only to the cases in which the differential coefficients become nothing, and not to that in which they become infinite. It is also frequently stated that there is always a maximum or minimum where a differential coefficient vanishes, which is not true.

MAXIMIA'NUS, MARCUS VALERIUS, a native of Pannonia, born of obscure parents, served in the Roman armies with distinction, and was named by Diocletian his colleague in the empire, A.D. 286. The remainder of his life is given under **DIOCLETIAN**, **CONSTANTINE**, and **MAXENTIUS**. He was put to death at Marseille, by order of Constantine, for having conspired against his life, A.D. 310.

Coins of Maximianus.
British Museum. Actual size.

MAXIMIA'NUS, GALE'RIUS VALE'RIUS, was surnamed **Armentarius**, on account of having been a herdsman in his youth. The events of his life are narrated under **DIOCLETIAN**, **CONSTANTIUS I.**, and **CONSTANTINE**. According to the historians, he died (A.D. 311) of a loathsome disease, which was considered by his contemporaries and himself as a punishment from heaven for his persecution of the Christians.

Coin of Galerius Valerius Maximianus
British Museum. Actual Size.

MAXIMILIAN. [**HABSBURG, HOUSE OF.**]
MAXIMI'NUS, CAIUS JULIUS VERUS, was originally a Thracian shepherd. He was of gigantic size and great bodily strength. He entered the Roman army under **Septimius Severus**, and was rapidly advanced for his bravery. **Alexander Severus** gave him the command of a new legion raised in Pannonia, at the head of which he followed **Alexander** in his campaign against the Germans, when the army being encamped on the banks of the Rhine, he conspired against his sovereign, and induced some of his companions to murder him in his tent, as well as his mother **Mammæa**, A.D. 235.

Maximinus, being proclaimed emperor, named his son, also called **Maximinus**, **Cæsar** and his colleague in the empire. He continued the war against the Germans, and devastated a large tract of country beyond the Rhine, after which he repaired to Illyricum to fight the **Dacians** and **Sarmatians**. But his cruelty and rapacity roused enemies against him in various parts of the empire. The province of **Africa** revolted, and proclaimed **Gordianus**, who was soon after acknowledged by the senate and the people of Rome, A.D. 237.

But **Capellianus**, governor of **Mauritania** for **Maximinus**, defeated **Gordianus** and his son, who fell in the struggle, after a nominal reign of little more than a month. [**GORDIANUS, MARCUS ANTONIUS AFRICANUS.**] Rome was in consternation at the news, expecting the vengeance of **Maximinus**. The senate proclaimed emperors **Clodius Pupienus Maximus** and **Decimus Cælius Balbinus**, but the people insisted upon a nephew of the younger **Gordianus**, a boy twelve years of age, being associated with them. **Maximus** marched out of Rome with troops to oppose **Maximinus**, who had crossed the **Isonzo** and laid siege to **Aquileia**. **Maximinus** experienced a brave resistance from the garrison and people of that city, which excited still more his natural cruelty, and the soldiers, being weary of him, mutinied, and killed both him and his son, A.D. 238. **Maximinus** the father, then sixty-five years old, was a ferocious soldier and nothing else, and wonderful tales are related of his voracity, and the quantity of food and drink that he swallowed daily. His son is said to have been a handsome but arrogant youth. (**Capitolinus**, in *Historia Augusta*.)

Coin of Maximinus.
British Museum. Actual Size. Copper.

MAXIMI'NUS, DAIA, or DAZA, an Illyrian peasant, served in the Roman armies, and was raised by **Galerius**, who was his relative, to the rank of military tribune, and lastly to the dignity of **Cæsar**, A.D. 303, at the time of the abdication of **Diocletian** and **Maximianus**, when he had for his

share the government of Syria and Egypt. After the death of Galerius, A.D. 311, Maximinus and Licinius divided his dominions between them, and Maximinus obtained the whole of the Asiatic provinces. Both he and Licinius behaved ungratefully towards the family of Galerius, their common benefactor. Valeria, the daughter of Diocletian and widow of Galerius, having escaped from Licinius into the dominions of Maximinus, the latter offered to marry her, and on her refusal banished her with her mother into the deserts of Syria. He persecuted the Christians and made war against the Armenians. A new war having broken out between Licinius and Maximinus, the latter advanced as far as Adrianople, but was defeated, fled into Asia, and died of poison at Tarsus, A.D. 313.

MA'XIMUS, CLODIUS PAPIENUS. [BALBINUS.]
MAXIMUS PLANU'DES. [PLANUDES.]
MA'XIMUS MAGNUS. [GRATIAN; THEODOSIUS.]

Coin of Maximus Magnus.
British Museum. Actual Size. Gold.

MA'XIMUS TY'RIOUS, a rhetorician and Platonic philosopher, lived in the latter half of the second century, during the reigns of the Antonines and of Commodus. He resided principally at Athens, but sometimes visited Rome: he does not seem to be the same person as the stoic Claudius Maximus, who was one of the philosophical friends of the emperor M. Aurelius, though some critics have been of this opinion. (*Life of Aurelius*, by J. Capitolinus, c. 3.)

There are extant forty-one dissertations (*διαλέξεις* or *λόγοι*) of Maximus Tyrius on various points connected with the Platonic philosophy, which are written in an easy and pleasing style, and more commendable for the expression than the matter. The following examples will give some idea of the subject of these dissertations:—‘On Plato's opinion respecting the Deity;’ ‘Whether we ought to return Injuries done to us;’ ‘Whether an Active or a Contemplative Life is to be preferred;’ ‘Whether Soldiers or Husbandmen are more useful in a State;’ ‘On the Dæmonium of Socrates;’ ‘Whether Prayers should be addressed to the Deity.’ &c.

The best editions of Maximus Tyrius are by Stephanus, Paris, 1557; by Heinsius, Leyden, 1607, 1614, reprinted at Oxford, 1677; by Davis, Cambridge, 1703, reprinted at London with notes by Markland, 1740. The dissertations have been translated into French by Morel, Paris, 1607, by Forney, 1764, and by Dounais, 1802; into Italian by Petro de Bardi, Venice, 1642; and into German by C. T. Damm, Berlin, 1764. There is, we believe, no English translation of this author.

There were several other ancient writers of the name of Maximus, of whom the most celebrated was Maximus of Ephesus, who initiated Julian into the Eleusinian mysteries, and had subsequently great influence in the councils of that emperor.

MA'XIMUS, THE GREEK, a celebrated personage in Russian church history, was a native of Arta in Albania, where he was born towards the end of the fifteenth century. After studying at Paris, Florence, and other cities then distinguished as seats of learning, he entered the cloister of Mount Athos, where he took the monastic vows; but the grand-duke Vassili Ivanovitch, having desired the patriarch of Constantinople to send two persons to arrange and describe a vast number of Greek manuscripts and books that had recently been discovered in some part of the palace, the choice fell upon Maximus for one of them. He

accordingly set out for Moscow, and was astonished to meet with such a prodigious store of Greek literature. He was directed by Vassili to examine the books, and to select such as were most deserving of translation; but as he was then wholly ignorant of the Slavonic tongue, he had first to prepare a Latin version, which was afterwards rendered by others into Slavonian. It was thus that the translations of a Psalter with a commentary, and Chrysostom's ‘Homilies on St. John,’ were produced. Desirous of returning to his convent, it was only at the instances of the Tzar, who wished him to revise the earlier translated books of the Greek church, that he remained and undertook that task, for which he was then qualified by having obtained in the interim a competent knowledge of Slavonian. The diligence with which he executed it tended however only to raise up numerous enemies against him, among the rest Daniel, the metropolitan; for the corrections he deemed it requisite to make were so numerous as to give great offence to the more zealous. What more immediately tended to his disgrace was the firmness with which he opposed Vassili's divorce from his first wife Salome (on account of barrenness), and his marriage with the princess Helena Glinski. He was condemned by a synod, excommunicated as a heretic, and imprisoned in the Otrotch monastery at Tver, in 1525; in this confinement he was treated with great rigour till the death of the metropolitan Daniel; after which the bishop of Tver interceded for him and obtained some mitigation of the severity used towards him. At length the next Tzar, Ivan Vassilivitch, consented to his being removed to the monastery of St. Sergius, where he continued until his death in 1556. A great number of works are extant by him (chiefly in manuscript) on a variety of subjects, dogmatical, polemical, philosophical, &c.; from which considerable information has been derived with regard to the opinions and prejudices of the clergy and people in that age; nor was he at all timid in reproving the abuses and vices of the times. This alone would account for the persecution which he drew down upon himself; but after his death even those who had been among the more violent against him, admitted his innocence, nor was it long before his memory came to be regarded as that of a holy man and a martyr.

MAXWELL, ROBERT, LORD, son of John, third Lord Maxwell, who was killed at Flodden, in September, 1514. He had been knighted, and appointed Stewart of Annandale, on the resignation of his father, on the 10th of June preceding; and in 1517 he was appointed warden of the West Marches. In 1524 he was provost of Edinburgh, and in that capacity chosen one of the lords of articles for the commissioners of boroughs: a solitary instance, it is supposed, of a peer being so elected. He was afterwards chosen one of the privy-council; and on the 17th of November, 1533, appears in the sederunts of the Court of Session as an extraordinary lord of session. In 1536 he was appointed one of the lords of the regency to whom the government of the kingdom was entrusted during the absence of King James V. on his matrimonial expedition to France; and the next year he was himself despatched to negotiate the marriage of Mary of Lorraine. He is said to have advised the expedition which terminated at Solway Moss, but was so incensed at the command of the army being given to Oliver Sinclair, that in common with most of the Scots nobility he mutinied and yielded himself up a prisoner to the English, who had a force much inferior to their opponents. On the death of King James V. he was ransomed and allowed to return to Scotland, in the hope that he would further the projects of King Henry VIII., in reference to the marriage of the young queen of Scots. In the first parliament of Mary, which met in March, 1543, he presented to the lords of articles one of the most important acts of the time, which had undoubtedly considerable effect in accelerating the progress of the Reformation. This was a writing, or as we should now term it, a *Bill*, for an act of parliament to allow the reading of the Scriptures in the vulgar tongue. The lords of articles found the proposal reasonable; and it was accordingly brought into parliament, and passed into a law notwithstanding the protest and opposition of the lord chancellor and the whole hierarchy of the kingdom. Towards the end of the same year, Beaton became chancellor, and Lord Maxwell was apprehended, but he contrived to make his escape almost immediately after. He died on the 9th of July, 1546.

MAY, the fifth month of our present year, was the second in the old Alban calendar, the third in that of Romulus,

and the fifth in the calendar of Numa Pompilius. In the Alban calendar it consisted of twenty-two days; of thirty-one in the calendar of Romulus; and of thirty in that of Numa. Julius Cæsar restored to it the odd day of which Numa had deprived it, and of which it still keeps possession. Its etymology is doubtful. Ovid, in the fifth book of his 'Fasti,' proposes three derivations: one from *majestas*; another from *maiores*, a term which signified the *patres*, or governing body of the city of Romulus; and the third from *Maia*. The Roman month was under the protection of Apollo; and on account of the celebration of the Lemuria, marriages undertaken during its course were considered ill-omened. (Ovid, *Fasti*, v. 483-490.)

Our Saxon ancestors, after the Romans, called it *Maus-month*; and, in their native language, *Tri-milcni*, three-milk month, when cows were milked three times a day.

MAY-DAY and **MAYING**. It was antiently the custom, observes Brand, for all ranks of people to go out a-maying early on the first of May. Bourne (*Antiq. Vulg.*, ch. xxv.) tells us that, in his time, in the villages in the north of England, the juvenile part of both sexes were wont to rise a little after midnight on the morning of that day, and walk to some neighbouring wood, accompanied with music and the blowing of horns, where they broke down branches from the trees, and adorned them with nosegays and crowns of flowers. This done, they returned homeward with their booty about the time of sunrise, and made their doors and windows triumph in the flowery spoil.

There was a time when this custom was observed by noble and royal personages as well as the vulgar. Chaucer, in his 'Court of Love,' says that early on May-day, 'Fourth goth al the court, both most and lest, to feteche the flowris fresch, and braunch, and blome.'

It is on record that King Henry VIII. and Queen Katherine partook of this diversion; and historians also mention that he, with his courtiers, in the beginning of his reign, rose on May-day very early to fetch May or green boughs; and they went, with their bows and arrows, shooting to the wood. Shakspeare ('Henry VIII.,' act v., scene 3) says, it was impossible to make the people sleep on May morning; and ('Mids. Night's Dream,' act iv., scene 1) that they rose early to observe the rite of May. The court of King James I. preserved the observance of the day, and it was long continued by the populace, as Spelman's 'Glossary' remarks, under the word 'Mainma.'

Two or three minor observances still remain to be slightly noticed. The may-pole, decked with garlands, round which the rustics used to dance in this month, yet stands in many of our villages through the whole circle of the year; and chimney-sweepers with their Jack-in-the-green continue to dance in the streets of London. A may-pole formerly stood in the Strand, upon the site of the church by Somerset House, but was taken down in 1717.

Misson, in his 'Travels' (see Ozell's *Translation*, p. 307), notices a custom which has now gone by for forty years. The country girls who served London with milk, accompanied by a fiddler and a garland of plate (hired from a silversmith) adorned with flowers, danced before the doors of their customers.

Most of the rites here enumerated had, no doubt, their origin in the heathen observances practised at this season of the year in honour of Flora, the deity who presided over fruits and flowers. (Hospinian, *De Festis Judæorum et Ethnæcorum*, fol. 100.)

Polydore Virgil notices the prevalence of May customs in Italy. An account of some of those observed in France will be found in the 'Mémoires de l'Académie Celtique,' tom. iii., p. 446; and Dr. E. D. Clarke, in his 'Travels,' vol. i., 4to., Cambr., 1810, p. 110, notices the promenades and other observances on the first of May at Moscow, among the sights there most interesting to a stranger. See also Brand's *Popular Antiquities*, 4to. edit., vol. i., p. 179-204.

MAY-WEED (*Anthemis arvensis*, or Wild Chamomile), a troublesome weed in corn, which is difficult to eradicate, as it is propagated both by seed and by the low running branches which strike into the soil and take root. It flowers in May, as its name denotes, and sheds its seed long before the corn is reaped. The only certain mode of exterminating it is by great care in clearing the land when it is sowed or prepared for turnips, ploughing it in as soon as the flowers appear, and never allowing it to go to seed. In the alternate system it is soon got rid of by the hoeing of the green crops; clover also kills it

when the land is in good heart, and in the convertible husbandry it is destroyed while the land is in grass, and mown. It is a sure sign of a slovenly husbandry when the land is covered with May-weed. It often infests farms which have been neglected by outgoing tenants, and it is indispensable to get rid of it before any attempt at improvement is made. A good clean fallow is the surest means of destroying this as well as all other annuals: by repeated harrowings the seeds are first brought to the surface, where they vegetate, and are afterwards destroyed. The time to do this is in dry weather, interspersed with occasional showers, as in the months of April, May, and June.

MAY, THOMAS, an early English dramatist and historian, was born in 1595. He was the son of Sir Thomas May, who was descended from an antient family in the county of Sussex. Having finished his education at Sidney College, Cambridge, he came to London, and made the acquaintance of several persons of distinction.

In 1637 May was opposed to Sir William Davenant as candidate for the office of laureate, which the death of Ben Jonson had left vacant. Sir William was successful, and his success so exasperated May, that although hitherto a courtier, he became hostile to the king's party, and wrote a history in favour of the parliament. In 1650 he was found dead in his bed. It is supposed that he was strangled by the tightness of his nightcap-strings. He was buried in Westminster Abbey, near John Camden the historian; but his body was taken up after the Restoration, and removed to a large pit in the church-yard of St. Margaret's, Westminster, and his monument in the abbey pulled down.

Besides a history of parliament, he wrote a history of Henry II., and made a translation of Lucan's 'Pharsalia,' with a continuation both in Latin and English. His plays are supposed by some to be five in number, and these five are named 'Agrippina,' 'Antigone,' 'Cleopatra,' 'The Heir,' and 'The Old Couple.' The last two are comedies, and are printed in Dodsley's Collection. Phillips and Winstanley ascribe to him two other plays, called 'The Old Wife's Tale,' and 'Orlando Furioso,' but the dates assigned to the first publication of these pieces, if correct, render the supposition impossible.

MAYBOLE, a parish and market-town in the district of Carrick and county of Ayr. The town is pleasantly situated upon a small eminence surrounded by hills, and its direct distance is about 5 miles from the sea-coast and 70 south-west by west from Edinburgh. It was erected into a burgh of barony by a charter of James V., dated 24 Nov., 1516, but it was not till the commencement of the following century that the burgesses appear to have availed themselves of the privilege thus conferred upon them of electing their own magistrates. The management of the affairs of the burgh is vested in a council, consisting of seventeen members, who hold their office during life. The revenue, derived from landed property and an annual tax called 'stint,' averages 65*l.* per annum, which is about equal to the expenditure. The streets are cleansed and kept in repair at the expense of the turnpike-road trust-fund of the county. None but burgesses can legally carry on any manufacture or trade within the burgh; the charge for admission into their body is 1*l.* 1*s.* or 10*s.* 6*d.*, according as the applicant is a stranger or the son of a freeman. There are however no manufacturing establishments, although the chief part of the inhabitants are employed in hand-loom weaving for the Glasgow houses. The principal building is the church: it is large, and surmounted by a steeple in very bad taste. The population of the parish in 1831 was 6287, of which it is estimated that rather more than one-half were resident within the boundary of the burgh. There are in all thirteen schools, and one of these, called the 'subscription school,' is chiefly supported by the Irish inhabitants. There are also a savings' bank and several philanthropic institutions.

In the tavern of the 'Red Lion' is shown the room where Knox, and Kennedy, the abbot of Crossraguel, accompanied by eighty of the nobility and gentry of the country, assembled, the former to impugn the mass, the latter to defend it; and the inhabitants have since instituted a "Knox Club," which holds triennial festivals, at which men of all parties meet to testify their gratitude for their deliverance from the domination of Rome, and their secure enjoyment of Protestant principles, achieved for them by Knox and his coadjutors.

(*New Statistical Account of Scotland; Parliamentary Report on Scotch Burghs, &c.*)

MAYENCE. [MAINZ]**MAYENNE. (River and Town.) [MAYENNE.]**

MAYENNE, a department in the western part of France, bounded on the north by the departments of Manche and Orne, on the east by that of Sarthe, on the south by that of Maine et Loire, and on the west by that of Ille et Vilaine. Its form approximates to that of a parallelogram, having an average length of 50 or 52 miles from north by east to south by west, and an average breadth of 38 miles from east to west. Its area is estimated at 1994 square miles, being below the average area of the French departments, and almost equal to that of the English county of Norfolk. The population in 1831 was 352,586; in 1836 it was 361,765, showing an increase in five years of 9179, or between 2.5 and 3.0 per cent., and giving more than 181 inhabitants to a square mile. In density of population it is above the average of France, but rather below the English county with which in area we have compared it. Laval, the capital, is on the Mayenne, 149 miles in a direct line west-south-west of Paris, or 169 miles by the road through Dreux, Alençon, and Mayenne, in 48° 4' N. lat., and 0° 48' W. long.

The northern part of the department is the most elevated. The principal range of the Armorican chain of mountains, and the branch from it which separates the basin of the Loire from that of the Vilaine, skirt the western border, the hills gradually subsiding as they proceed southward. Another branch of the Armorican chain skirts the eastern border, subsiding into the plain sooner than the western branch, to which it is parallel. These two branches enclose the valley watered by the Mayenne and its tributaries. The department is almost entirely occupied by the rocks of earlier formation, being included in the great primitive district of Bretagne. There was in 1834 one coal-mine in the department, giving employment to above a hundred men, and yielding about 5000 tons annually. There were also five mines of anthracite (besides two others not worked), giving employment to more than 350 men; and yielding annually 18,000 tons. Some iron-ore is procured; the number of iron-works in 1834 was five, having eight furnaces for smelting pig-iron and fifteen forges for making bar-iron. Charcoal was the fuel almost exclusively employed. Freestone, slates, and marble are quarried.

The principal river is the Mayenne, which rises just beyond the boundary of the department, near the north-eastern corner, and flows westward (sometimes in this department, sometimes in that of Orne), 22 miles, to the neighbourhood of Lassay; from thence it flows southward 55 miles through the valley described above, to the boundary of the department, 26 miles beyond which it falls into the Loire below Angers. Its whole course is about 103 miles, of which it is navigable for 50 miles, viz. from Laval; 24 miles of the navigation are in this department. The official returns make the total navigation 59 or 60 miles, of which about half is in this department. The feeders of the Mayenne are none of them navigable in this department; the principal are the Varenne, the Colmont, the Ernée, and the Oudon, which join the Mayenne on the right bank, and the Jouanne, which joins on the left. The Erve, which waters the east side of the department, falls into the Sarthe, which just touches the south-east corner. There are many large pools (the chief are in the upper part of the Oudon and the Vicoin, a small feeder of the Mayenne), and many brooks.

The number of Routes Royales, or government roads, in 1837, was five, having an aggregate length of 157 miles, viz. 107 in repair, 44 out of repair, and 6 unfinished. The principal road is that from Paris to Rennes and Brest, which enters the department on the north-east, runs south-west by Pré-en-Pail to Mayenne, and from thence south by west by the valley of the Mayenne to Laval, where it turns off to the west and quits the department. Roads from Laval run southward by the valley of the Mayenne through Château-Gonthier to Angers (Maine et Loire), south-east by Meslay to La Flèche (Sarthe), and eastward to Le Mans (Sarthe). Roads from Mayenne lead northward to Domfront (Orne) and Caen (Calvados), and westward to Fougères and St. Malo (Ille et Vilaine). There are also several departmental roads, having an aggregate length of 178 miles, viz. 109 miles in repair, 17 out of repair, and 52 unfinished. The bye-roads and pathways have an aggregate length of 2500 miles.

About two-thirds of the soil of the department are under the plough. Wheat is not much cultivated; rye, barley,

oats, and especially buckwheat, are more commonly raised. The northern part of the department is sterile, the centre of moderate fertility, but the southern part produces abundant harvests. Much hemp and flax are grown, and there are extensive orchards, especially of apple and pear trees, from the fruit of which a great quantity of cider and perry is made. There are few vineyards, and the wine which they produce is of ordinary quality; the department lies almost entirely beyond the line within which the vine can be cultivated to advantage. Among the vegetables cultivated is a gigantic variety of the cabbage, which grows above the height of a man. The pools produce a plant, 'the water chesnut,' the fruit of which, enveloped in a husk, floats on the surface of the water, and has, when roasted, the flavour of a chesnut. Meadows and grass lands, including the heaths and other open pastures, are extensive, occupying from one-fifth to one-sixth of the soil; the number of cattle reared is considerable, especially cows, from whose milk excellent butter is made; there are large flocks of sheep, the wool of which is in good repute; the horses are of small size; swine and poultry are numerous, and a vast number of bees are kept all over the department. The woodlands of the department are not extensive.

The peasantry are simple-minded but ignorant. Education is in a very low state, and superstition is predominant. The inhabitants however are religious, sincere, and honest. They are neither such industrious nor such skilful farmers as those in the neighbouring department of Sarthe, but are more regular and better tenants; buckwheat is still a favourite crop with them; trefoil is very little regarded. In the troubled times of the Revolution this department swarmed with Chouans, or royalist partisans; but on the subsidence of those troubles the peasantry returned to their ordinary pursuits, and at present in no part of France are the roads safer, property more respected, and political excitement less violent.

The department is divided into three arrondissements, as follows:—

	Area in sq. miles.	Population in 1831.	Population in 1836.	Com- munes.
Laval, central	703	117,534	122,755	92
Mayenne, north	820	162,164	164,618	110
Château-Gonthier, south	471	72,888	74,392	73
	1994	352,586	361,765	275

There are 27 cantons, or districts, each under a justice of the peace.

In the arrondissement of Laval are, Laval (population in 1831, 15,826 town, 16,401 whole commune; in 1836, 17,810 commune), on the Mayenne [LAVAL]; Montsurs, on the Jouanne; Evron (pop. 1846 town, 3750 whole commune), on the Dinard, a feeder of the Jouanne; Sainte-Suzanne, on the Erve; St. Onen and Loiron, in the country west of the Mayenne; and Meslay, on the road from Laval to La Flèche. Evron is a busy place, with a good weekly market and ten yearly fairs, situated in an excellent wheat district. The town has a tolerably handsome market-house, a Benedictine abbey, now occupied by the Sœurs de la Charité, and a conventual church, with a fine choir. Sainte-Suzanne is a small town of about 1000 inhabitants, on a high hill. It was once a place of strength. It has the ruins of an old castle, and some old ramparts yet more in decay, vitrified in one part like the vitrified forts of Scotland. The French writer who describes this remarkable phenomenon (Vayasse de Villiers) contends for its being the effect of lightning; but as the place was occupied by the Northmen, to whom, under the name of Danes, the vitrified forts of Scotland are ascribed, the walls of Sainte-Suzanne may probably be ascribed to them. Meslay is a small place of about 1200 inhabitants, consisting chiefly of one street, well paved and lined with neat well-built houses. The neighbourhood produces abundance of corn.

In the arrondissement of Mayenne are Mayenne, Ambrières, Lassay (population 1676 town, 2807 whole commune), Couptrain, and Pré-en-Pail (pop. 3844 whole commune), on or near the Mayenne; La Poërie (pop. 2291 whole commune); Vilaine or Villaines-la-Juillet (pop. about 1200); and Bays, in the country east of that river; Gocé, on the Colmont; Ernée (pop. 3445 town, 5467 whole commune) on the Ernée; and Fougères, Lathury, Mantaudi, and St. Denis, in the north-west corner of the department. Mayenne is situated on the slope of two hills which face each

other, and are separated by the river Mayenne. The town, properly so called, is on the right bank, where the hill is highest; the part on the left bank is a suburb which contains about one-third of the whole population of the place; the two are connected by a bridge. The principal line of street is that which descends one hill, crosses the bridge, and ascends the other; this constitutes the road from Paris to Rennes by Fougères; the more frequented road by Laval just passes through the eastern extremity of the suburb. This principal street is neither wide nor straight, and the slope on the side of the town is so steep that in summer it requires a team of twelve, and in winter sometimes of thirty horses and oxen to draw up heavily laden carriages. Near the summit of the hill the street widens so as to form a place or opening divided by a modern town-hall into two parts, one of which is adorned by a fountain. At the summit of the hill on a slate rock is the ancient castle of the dukes of Mayenne, at present occupied as the town prison. The linen-hall or market is separated from this castle by a terrace planted with trees and used as a promenade. The town and suburb have each a parish church. The houses are mostly ancient, but the streets are very clean. The population of Mayenne in 1831 was 8758 for the town and suburb, or 9797 for the whole commune; in 1836 it was 9782 for the commune. The principal manufactures are of linens, calicoes, and handkerchiefs. There are three weekly markets: one for linen, cattle, and general commodities; another for corn, and a third for provisions: there are eight yearly fairs. The linen manufacture, which is the staple, is carried on not only in the town but in the surrounding districts, and employs 8000 persons; the raw material is chiefly foreign flax. There are, two or three miles west of the town, at Fontaine Daniel, a calico manufactory employing 500 persons; and about the same distance south, the wrought-iron forges of Aron. The town has a subordinate court of justice, an hospital, and a high school. Lassay has handsome market-houses and an ancient château. Much business in cattle and in flax is done at its weekly market and its two yearly fairs. Pré, or Prez-en-Pail, has a considerable weekly cattle-market. Ernée is laid out with tolerable regularity, and is pretty well built. It is the residence of several wealthy families who occupy handsome houses; it has a large market-place, in which is an ancient market-house. The town has no manufacture, and the district round it is purely agricultural.

In the arrondissement of Château Gonthier are, Château-Gonthier (pop. of the commune in 1831, 6143, and in 1836, 6226) on the Mayenne [CHATEAU-GONTHIER]; Baillé on the Erve; Grez-en-Bouère and St. Denis, in the country east of the Mayenne; and Craon (pop. 2550 town, 3610 whole commune) and Cossé-le-Vivien, on or near the Oudon. Craon has narrow and crooked streets, and plainly built houses. The market-house is large. The chief trade of the place is in flax. There is good society at Craon; Volney was a native of this place. Cossé-le-Vivien with 1000 to 1200 inhabitants, is situated in a fertile district, and is the seat of a considerable trade in linens.

The chief manufacture of the department is that of linen, including sail-cloth and table-linen. Flax spinning and weaving form the occupation of a large portion of the working class in the arrondissement of Mayenne, the sterile soil of which affords little encouragement to agriculture; but the rate of wages is low, and the intervals of depression to which manufactures are liable occasionally throw the work-people into great distress. Laval and Mayenne are the chief seats of this manufacture; but the population of the arrondissement of Laval is more agricultural than that of Mayenne. The decline of the linen manufacture, induced by the extended use of cotton fabrics, has led to the introduction of the manufacture of calicoes and cotton handkerchiefs into both those towns. Some woollen stuffs and paper are also made. These manufactures, with wood for fuel and for building ships, iron, marble, slates, and various articles of agricultural produce, constitute the chief articles of export.

The department is comprehended, with that of Sarthe, in the diocese of Le Mans; the bishop of which is a suffragan of the archbishop of Tours. It is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Angers, and is comprehended in the fourth military division, of which the head-quarters are at Tours. It sends five members to the Chamber of Deputies.

This department was comprehended, in the most ancient historic period, in the territory of the Diablantes, the

Arvi, and the Andes or Andecavi, three Celtic nations, which under the Roman domination were comprehended in the province of Lugdunensis Tertia. The ancient name of the river Mayenne in a Romanized form was Meduana. Næodunum (afterwards Diablantes) and Vagoriturum, the respective chief towns of the Diablantes and the Arvi, were within the limits of the department. Of the first, now the village of Jublins, there are important remains. There are the walls of a Roman station forming nearly a square of 600 or 700 feet each way, with towers on the sides and at the corners. The walls are scarcely more than seven or eight feet high, and about nine feet thick; composed of layers of square stone, alternating with three tiers of brick, and the whole united by a very hard cement. It is one of the most firmly built and best preserved Roman forts in France. Within the enclosure are the traces of buildings probably occupied by the garrison of the fort. A subterranean apartment was discovered near the fort about seventy years ago, but covered up again to stop the troublesome visits of the curious. It had a mosaic floor and painted walls. An ancient well has also been discovered, and medals and rings have been dug up. There is at Jublins a granitic rock presenting a resemblance to a chair, supposed to be a Druidic monument. It is popularly called 'the Devil's chair.' There are some remains of a town supposed to be Vagoriturum, now called Arve, or Erve, on the river Erve. From this name it has been inferred with great probability that the town, like the other chief towns in Gaul, took at a later period the name of the people to whom it belonged. The first syllable of the name Vagoriturum appears to be preserved in that of the Vaige, a small stream flowing parallel to the Erve, about a mile or two from it. In the middle ages the department was comprehended chiefly in the province of Maine, but a small part of it in that of Anjou. [ANJOU; MAINE.] This part of France suffered much in the Vendéan war.

MAYER, TOBIAS, was born at Marbach, a town of Wurtemberg, on the 17th of February, 1723. His father was a civil engineer, and held the appointment of inspector of the water-works (inspecteur des eaux) at Esslingen. From him young Mayer received some elementary instruction in the mathematics, but it could not have been much, since we read that he was left an orphan and unprovided for at a very early age. To gain a livelihood he began teaching the mathematics, and at the age of twenty he studied the principles of gunnery, probably with a view of entering the army. In the year 1746 he took an active part in the establishment of the Cosmographical Society of Nürnberg, to whose Transactions he afterwards contributed several interesting memoirs. Among these is one, published in 1750, 'On the Libration of the Moon,' in which, besides treating the subject in a very able manner, he then for the first time employed 'equations of condition,' which are now of such extensive and important application. [CONDITION.] In 1751 he became director of the observatory at Göttingen, and at the same time or subsequently was appointed professor of economy in that university, which appointment was probably a sinecure, since it does not appear that he ever taught any subject but the mathematics and their application. At Göttingen, during the remainder of a very short life, he laboured with the most praiseworthy zeal to promote the sciences of geography, navigation, and astronomy. His 'Zodiacal Catalogue' was 'deserving of all confidence' (Delambre), and comprised 998 stars, including those whose correct positions are of most importance to the astronomer. In 1755 he published his 'Lunar Tables' in the 'Acts of the Academy of Göttingen,' and a copy of them was forwarded to the London Board of Longitude. By order of the board the accuracy of the tables was rigorously tested by Dr. Bradley, who was able in no instance to detect an error greater than 1' 30" (the error of the other tables then existing sometimes amounted to 10'), and even part of this he was of opinion might be fairly attributed to his own observations. (See Dr. Bradley's *Letter to the Secretary of the Admiralty*, dated 10th February, 1756.) These tables were printed by the Board of Longitude in the year 1767, and likewise the 'Solar Tables' by the same author in the year 1770. After the death of Mayer the British parliament, at the recommendation of the Board, paid his widow the sum of 3000*l*. The original resolution of the Board, dated 9th of February, 1765, recommends that a sum 'not exceeding 5000*l*.' should be awarded; and Delambre states that a further sum of 2000*l*. was subsequently paid; but this

is a mistake. The act of parliament awarding the 3000*l.* is that of 5 Geo. III., c. 20; and the later acts relating to the Board of Longitude make no further mention of Mayer's widow. To Mayer is also due the discovery of the principle of the repeating circle, which was afterwards so fully developed by Borda, and employed by him in the measurement of the arc of the meridian. [BORDA; REPEATING CIRCLE.] Mayer died at Göttingen on the 20th of February, 1762. His éloge was spoken by Kaestner (Gött., 4to., 1762). In 1801 a simple monument was erected to his memory at Göttingen, the place of his interment.

The following list of his published works is given by M. Delambre from the 'Eloge' of Mayer by Kaestner:—'Description of a new Globe of the Moon' (Nürnberg, 1750); 'Terrestrial Refractions'; 'Geographical Maps'; 'Description of a new Micrometer'; 'Observations of the Solar Eclipse of 1748'; 'Conjunctions of the Moon and Stars observed in 1747-8'; 'Proofs that the Moon has no Atmosphere'; 'Motion of the Earth explained by a Change in the Direction of Gravity'; 'Determination of the Latitude of Nürnberg, with other Astronomical Observations'; 'Mémor on the Parallax of the Moon, and upon the Distance of that Satellite from the Earth, as deduced from the Length of the second Pendulum'; 'On the Transformation of Rectilinear Figures into Triangles'; 'Inclination and Declination of the Magnetic Needle, as deduced from Theory'; 'On the Inequalities of Jupiter.' In addition to the above there appeared at Göttingen, in 1775, in folio, edited by George Lichtenberg, his successor at the observatory of Göttingen, the first volume of what was intended to be a complete edition of Mayer's works. This, which is the only volume that has been published, consists of six memoirs entitled, 1, 'A Method of determining more correctly the Variations of the Thermometer: a Formula for determining the mean Temperature of different Latitudes, and the Period of the Year corresponding to the greatest Intensity of Heat and Cold'; 2, 'Observations made with his mural Quadrant of six feet radius'; 3, 'An easy Method of calculating the Eclipses of the Sun'; 4, 'A Mémor on the Affinity of Colours,' wherein he recognises but three primitive colours; 5, his 'New Catalogue of Stars'; 6, 'A List of Eighty Stars,' in which he believed he had detected a motion, in addition to that resulting from the precession of the equinoxes.

('Notice of the Life of Mayer,' by M. Delambre, in the *Biog. Univ.*; Hutton's *Mathematical Dictionary*; and Montucla, *Hist. des Math.*)

MAYNOOTH. [KILDARE.]

MAYO, a maritime county of the province of Connaught, in Ireland, bounded on the east by the counties of Sligo (from which it is separated by the river Moy) and Roscommon, on the south by the county of Galway, and on the west and north by the Atlantic Ocean. According to the ordnance map of Ireland, constructed for the Irish railway commissioners in 1836, it lies between 53° 27' and 54° 19' N. lat., and between 8° 31' and 9° 20' W. long., and extends from Achil Head on the west to the junction of the Sligo and Roscommon boundaries at Ballaghaderreen on the east, 72 statute miles, and from the centre of Loch Corrib on the south to Downpatrick Head on the north, 58 miles. The length of the coast-line from the mouth of the river Moy on the north-east to the head of the Killery Harbour on the south-west, exclusive of the minor indentations of the shore, is about 250 statute miles. The area, as ascertained by the ordnance survey, has not yet been made public. According to the map constructed under the superintendence of the Society for the Diffusion of Useful Knowledge, it contains 1,023,273 English acres, or 1598 square statute miles. According to Mr. Griffith's estimate, it consists of

Cultivated land	871,984 statute acres.
Unprofitable bog and mountain	425,124 "
Water	57,940 "

Total 1,355,048 statute acres, or 2117 square statute miles, being next to Cork and Galway, the third largest county in Ireland. In 1831 the population was 367,956.

Mayo has a very diversified surface, embracing a part of the great inland plain which extends across the centre of the island, together with a large extent of wild and mountainous country interposed between the western verge of that plain and the sea. The mountain region consists of two principal districts, separated from one another by Clew

Bay, a capacious inlet of the Atlantic, which, running inland to a distance of fifteen miles, by from seven to eight miles in width, meets the western extremity of the plain at Westport. The mountain groups lying south of Clew Bay cover the entire barony of Murrisk, and stretch beyond the bounds of the county into the highlands of Joyce Country and Connemara. [GALWAY.] The area which they cover within the limits of Mayo is about fifteen miles by twenty, and is bounded on the north by the level land about Westport and by Clew Bay, on the west by the Atlantic Ocean, on the south by the long narrow inlet of the great Killery Harbour and the Joyce Country mountains, and on the east by the flat country constituting the basin of Lough Mask and Carra. The most easterly of the various mountain groups comprised within these limits is constituted by the Furrnamore and Partry Mountains, which, extending in a north-easterly direction from the head of the Killery, form a continuous range of fifteen miles in length, rising abruptly over the western shores of the above-mentioned lakes. The elevation of Furrnamore, rising about midway between the Killery Harbour and Loch Mask, is 2210 feet. The other chief summits of the range are Bengorriff, near its southern extremity, 2038 feet, and Slieve Bôhaun, terminating it on the north, 1294 feet.

On both sides of the chain are bold ravines, traversed by streams descending on the one hand into Loch Mask, and on the other into the valley of the Owen Errive river, which runs southward into the head of Killery Harbour, and also into the valley of the Ayle. The Ayle, running northward through the first part of its course, dips underground immediately on emerging from the mountain district, and, passing eastward round the terminus of the range for two miles under the limestone-rock of the plain, rises again and flows southward, along the opposite side of the mountain, into the head of Loch Mask. One of the sources of the Owen Errive is the Lake of Glenawagh, which lies in what is locally termed a *prison*, being a bowl-shaped hollow in the northern side of Furrnamore, surrounded by perpendicular precipices 1500 feet high. West of the valley of the Owen Errive lies the group of Muilrea, skirting the northern shore of the Killery, and extending inland in a direction generally parallel to that of the range of Slieve Partry. Muilrea Mountain, which rises immediately over the northern entrance to the harbour, is the highest ground in the county, being 2682 feet in altitude. Next in the range, eastward, is Benberry, 2610 feet; between which and Bengorm, 2224 feet, lie the romantic lakes of Doolough and Delphi, with the shooting-lodge of the Marquis of Sligo. These heights, as they trend eastward, are broken into numerous lateral valleys, of which the most considerable is Glen Lawr, watered by the main branch of the Owen Errive. Above Glen Laur the highest point of the range is 2429 feet. Northward from the immediate group of Muilrea the centre of the district of Murrisk rises into undulating hills of from 900 to 1200 feet in height, the general slope of the country being towards the north-west, in which direction most of the streams rising in the interior make their way through openings in the hilly country to the sea. The northern verge of Murrisk, bordering on Clew Bay, is occupied through a length of ten miles by the range of Croagh Patrick, running parallel to the shore. Croagh Patrick, locally called the Reek, rises immediately from the water's edge in the centre of the range to an altitude of 2610 feet, presenting a very perfect conical outline on every side, and forming by much the most conspicuous feature in the surrounding scenery. The general character of this district is sterile, though among the undulating hills of the central part there are extensive tracts of coarse pasture. The only place having the character of anything more than a hamlet throughout the entire tract is the little village of Louisburg, near the coast on the north-west.

The mountainous district lying north of Clew Bay is of considerably greater area, extending upwards of forty miles from east to west, by thirty miles from north to south. Separated from the range of the Ox mountains in Sligo by the valley of the Moy and the low basin of Loch Conn, thus standing insulated in the north-western part of the county, it nevertheless corresponds, in the direction of its principal groups, both with the range above mentioned on the east, and with that of the Slieve Partry mountains on the south. The Croagh Moyle mountains, forming the most advanced group towards the plain, appear as a continuation of the Sligo highlands, running in a direction from north-east to

south-west, from the valley of the Moy to the head of Clew Bay at Newport. The highest point of this range is 1655 feet. Corresponding in direction with the Croagh Moyle range is the group of Nephin, which extends from Loch Fyough, near the northern shore of Clew Bay, at a distance of about five miles from the exterior range, to the western shore of Loch Conn. The chief summits of this range, commencing from the west, are, Buckoragh, 1922 feet, Bercon Curragh, 2295 feet, and Nephin, 2646 feet; the last, being the highest ground in this district, forms an object of great grandeur, rising abruptly over the western verge of Loch Conn. In the intermediate valley bounded by these ranges, which constitutes the principal pass northwards from Newport, lie Loch Beltra, the waters of which run south-westward to Clew Bay at Newport, and Loch Lavalla, which discharges itself north-eastward into Loch Conn, the latter lying within the mountain-pass of Barn-na-gee. Northward from the range of Nephin lies a vast tract of comparatively level but extremely desolate moorlands, bounded towards the east by the fertile valley of the Moy, and westward by the nearly semicircular amphitheatre of the Tyrrawley and Nephin Bog mountains. A subordinate and nearly parallel ridge of low elevation divides this tract into two portions, the waters of one of which flow eastward by the Deel river to Loch Conn, and those of the other, passing through a gap in the centre of the range, run westward by the Owenmore river to the head of Blacksod Bay. The altitude of that part of the chain north of this gap is from 900 to 1200 feet; south of the valley of the Owenmore the heights are loftier and of a more striking outline, being broken into lateral valleys and defiles, and containing many small lakes surrounded by striking precipices. The chief heights here are Slieve Cor, 2368 feet, Nephin Beg, 2012 feet, and Cusheamcurragh, 2262 feet; the last rises immediately over the shore of Clew Bay, from which point the range takes a westerly direction, occupying the entire promontory of Corraun Achil, and beyond it, rising again into very bold eminences throughout the large island of Achil, which is separated from the mainland by a very narrow sound running up between Clew Bay and Blacksod Harbour. The surface of Achil Island is extremely mountainous, and its shores are perhaps more precipitous than any equal extent of coast in the British islands. At Minaun, on the south side of the island, the cliffs, which are slightly overhanging, have an altitude of 1000 feet and upwards; and at Keen Head, which terminates the island westward, the whole side of the mountain, which appears to have been rent asunder by some convulsion of nature, constitutes one shelving precipice of 2222 feet, springing immediately from the water's edge. The island is of a triangular shape, the northern and eastern sides being fourteen and twelve miles in length respectively, and the base, which faces the offing of Clew Bay towards the south-west, being fifteen miles in length. The northern side of the island constitutes the southern boundary of Blacksod Bay, a great arm of the Atlantic included between the wild district of Erris, which stretches westward from the chain of the Nephin Beg mountains on one side, and the low peninsula of the Mullet on the other. The Mullet, extending fifteen miles in length, is connected with the mainland of Erris by an isthmus five miles long by one mile on an average in breadth, which separates the head of Blacksod Bay from the head of the Bay of Broadhaven, included between the Mullet and the mainland in a similar manner on the north. The thriving little town of Belmullet is situated on the narrowest part of the isthmus, where it is only 400 yards wide. The peninsula is better tilled and less desolate than the mainland; there is a considerable village on it, called Binghamstown, near the head of Blacksod Bay; and Major Bingham, the chief proprietor, has a permanent residence farther south. The southern part of the peninsula is low and sandy, but the surface is varied on the north by some inconsiderable eminences, of which Slieve More, 432 feet in height, rising over the western entrance to Broadhaven, is the chief. From its comparatively level surface and the facilities for procuring sea-weed and sand for manure, this remote district possesses great capabilities of improvement; but the immense tract of bog and mountain interposed between it and the market towns of the interior has hitherto been a great obstacle to traffic. Nevertheless the town of Belmullet, which has sprung up since 1825, now consists of two streets of slated houses and a neat square, and has a yearly increasing export of grain. During the period of railway

speculation in Ireland, a few years ago, Belmullet was much spoken of as the terminus of a great western railway, by which it was proposed to open the vast desolate tract lying between it and the valley of the Moy, but the design has not been encouraged. Nothing can exceed the bleakness and sterility of the entire tract lying between the shores of Blacksod and Broadhaven bays and the valley of the Moy. On the western side of the Tyrrawley and Nephin Beg chain are numerous lakes, of which the greatest is Loch Carrowmore, five miles in length, which discharges its waters by the Owenmore river, famous for its salmon, into Tullaghan Bay, an arm of Blacksod Harbour. Between Tullaghan Bay and the Nephin Beg mountains lies the district of Ballycroy, where some herds of the red deer still survive. This part of Mayo has recently become pretty well known, as the scene of an interesting work entitled 'Wild Sports of the West.'

The remainder of the country, consisting almost wholly of open undulating plains, is divided by a low range of eminences running south of Castlebar into two principal districts, the waters of one of which run northward by the Moy to the sea at Killalla, and those of the other southward to lochs Mask and Corrib, and so to the sea at Galway. The district immediately surrounding Westport, the waters of which run westward to Clew Bay, is comparatively of inconsiderable extent. The valley of the Moy from the sea to Foxford, which is situated fifteen miles above the mouth of the river, is open, and contains much improved and improvable land, especially in the neighbourhood of Killalla [KILLALLA] and Ballina. Ballina, the third town in the county, about six miles above the estuary of the Moy, is situated partly in the county of Mayo and partly in the county of Sligo, the portion on the right bank of the river, which is within the latter county, being called Ardnaree. Ballina is of recent origin, there having been no town here prior to 1729, when Lord Tyrrawley gave the first impulse to industry in this district by the establishment of a cotton factory. The prosperity of the town has however been mainly owing to the enterprise of various traders who have been induced to settle here since the beginning of the present century in consequence of the local facilities for carrying on the grain and provision trades. In the vicinity of the town are numerous seats of resident gentry. Between Ballina and the range of Nephin is Loch Conn, a fine sheet of water eight miles in length by from one to four in breadth, communicating on the south, by a very narrow strait in the neck of land called the Puntoon, with Loch Cullin, a sheet of smaller dimensions, through which it discharges its waters into the river Moy close to Foxford.

The little town of Crossmolina, on the high road from Ballina to Belmullet, stands at the head of Loch Conn, and is surrounded by a tolerably fertile tract of country. The valley at Foxford is contracted by the approaching ranges of the Croagh Moyle and Slieve Gamph mountains, the latter constituting the western extremity of the Sligo group. Southward from this point the features of the valley are lost in the wide extended plain which opens inland. The hill of Slieve Carnon, rising to a height of 855 feet, is the only considerable eminence in this district. Running nearly north and south, it separates the vale of Castlebar on the west from the open tract spreading eastward into Roscommon, the former being watered by streams terminating in Loch Cullin, and the latter by the numerous and widely extended feeders of the Moy. The main stream of the Moy, rising in the county of Sligo, runs westward through an open upland valley bounded on the north by the line of the Ox mountains, and on the south by low undulating hills of from 600 to 700 feet in height, skirting the northern verge of the great plain. This vale is thinly inhabited, and much encumbered with mountain bogs; towards its western extremity however, near the point where the Moy, after receiving its tributaries from the southern plain, turns northwards, there is a good deal of cultivation round the small town of Swineford. Southward from the low range mentioned as bounding the valley of the upper Moy the country is more thickly inhabited and more productive. Under these eminences on the eastern verge of the county is the small town of Ballaghaderreen. The immediately surrounding district is bleak and swampy, but the bogs disappear on travelling westward and southward into the pastoral tract extending from the Roscommon border on the east, to the vicinity of Castlebar on the west, and from the

Slieve Carnon on the north to the borders of Galway on the south. This tract, embracing a very large extent of country, is named generally the Plains of Mayo, though the locality to which the name strictly applies is confined to the rich grazing lands immediately south of Slieve Carnon. The small town of Ballyhaunis is situated on the eastern verge of these plains, Claremorris near the centre, Hollymount on the south, and Ballyglass and Balla on the west. In the neighbourhood of the four last towns are numerous seats of resident nobility and gentry, among which Castlemacgarret, the residence of Lord Oranmore, near Claremorris, is the most conspicuous. The tracts of bog are also more numerous here than in the northern and central portion of the plain, occupying most of the valleys, and in several instances insulating the demesnes of the gentry. The country nevertheless, from the closeness of the demesnes and the quantity of timber, particularly about Hollymount and Ballyglass, has a rich appearance, which is considerably heightened by the vicinity of lochs Mask and Carra on the west, and by the extended mountain background on the west and north. South from Loch Carra and Hollymount an open fertile district extends along the eastern shore of Loch Mask, stretching inland without any incumbrance of unprofitable land as far as the border of Galway. This tract contains numerous private seats, and the small towns of Ballinrobe, situated on the river Robe near the point where it enters Loch Mask; Cong, situated on the narrow neck of land dividing Loch Mask from Loch Corrib; and Shrule, a poor village on the Galway border near Headford. The structure of the isthmus on which Cong is situated is very remarkable, the entire waters of lochs Mask and Carra passing by a subterraneous channel, which can in some places be approached by natural caves in the limestone rock at a depth of forty feet from the surface, to the lower basin of Loch Corrib. The scenery in this neighbourhood is very striking from the extent of water on all sides, and the grand mountain boundaries rising immediately over the western shores of both lakes.

The district surrounding the head of Clew Bay contains the towns of Westport and Newport, the former situated on a small stream running into the south-eastern angle of the bay, and the latter on the river which discharges the waters of Loch Beltra into its north-eastern angle. Westport is a well built and handsome town; two of the principal streets run parallel to the river, the borders of which are laid out as a public walk, with rows of trees. Westport House, the residence of the marquis of Sligo, by much the finest mansion in the county, stands in the immediate vicinity of the town, between it and the sea. From Westport to Newport the head of Clew Bay is studded over with green pasture islands, varying in size from a few acres to half a mile in length, and in number amounting to 170. The shore along the head of the bay is also good arable and pasture land, and is worn into numerous peninsulas and low promontories, many of them wooded, which greatly increases the picturesque effect. On one of these promontories is the residence of Sir Samuel O'Malley, Bart., a considerable proprietor; and at Newport also, close to the shore, is the seat of Sir Richard O'Donel, another owner of large tracts in the neighbourhood. The whole scenery of this district is remarkably striking; the beauty of the head of Clew Bay, with its labyrinth of islands, in particular, would appear to have been generally known from an early period, as they are distinguished as 'the Fortunate Islands,' in an Italian map of the sixteenth century.

The only harbour generally frequented on the northern coast is that of Killalla, formed by the embouchure of the river Moy. The bay is a square of about five miles each way, with a range of sandhills extending across the bottom. In this range there are two openings, one forming the bar of the Moy, and the other that of Killalla harbour. Formerly vessels for Ballina entered by the Killalla bar, and sailed by the lagoon at the back of the sandhills to the pool of Moyne, where they discharged by lighters; but since the execution of some improvements in the Moy a few years since, the navigation has been direct; and vessels of 200 tons now sail up to within a mile of Ballina. From Killalla bay westward the coast for a distance of twenty miles rises in lofty cliffs, affording very little shelter for craft of any kind. There are coves at Balderig, Port Terlin, and Port-a-cloy, where yawls can be kept, but these places, being open to the north and in immediate connection with the main sea, are always exposed to a heavy ground-swell. The last, which is a

narrow inlet bounded by steep cliffs of several hundred feet in height on both sides, has a depth of twenty-four fathoms at its mouth, and four fathoms close in-shore. This iron-bound coast continues to Benwood Head, between which and the north-eastern extremity of the Mullet is the entrance to Broadhaven. This bay consists of an outer and an inner harbour, the entrance to the latter being somewhat less than half a mile in width, in four fathoms water. The land-locked basin within runs up seven miles to Belmullet, and affords good anchorage throughout. The only use to which this fine harbour has been turned is the protection of a few row-boats employed in the fishery. The western shore of the Mullet has no shelter for vessels of burthen further than that afforded in western gales by an open anchorage under the lee of the Inniskea islands in the offing. The shores of the great bay of Blacksod Harbour afford numerous excellent roadsteads and several sheltered spots well adapted for landing cargoes. Of these the principal are Tarmon harbour, Killy harbour, and Sallee harbour, on the shore of the peninsula; Belmullet and Cleggan, at the head of the bay; and Tallaghan bay and the sound of Achil, on the shore of the mainland. The side of Achil facing the offing of Clew Bay is mostly a cliff with no shelter for any larger craft than boats, which may be drawn up on the beach in one or two coves. The southern shore of Corraun Achil is also for the most part ironbound. Neither is there any good shelter on the opposite coast of Murrisk bounding the lower part of Clew Bay on the south; but the upper end abounds with a multitude of safe and excellent anchorages, among the numerous islands between the creeks of Newport and Westport. The mouth of the bay also being covered for one-third of its breadth by Clare Island, the whole basin enjoys a considerable shelter from the prevalent run of the sea. The remainder of the coast of Murrisk between Clew Bay and the Killery possesses no harbours, but there is anchorage in westerly winds in four fathoms water under the lee of Innisturk Island in the offing. Innisbofin, another island constituting part of this county, although lying more off the coast of Galway, possesses a tolerable harbour, which was esteemed of such importance in the time of the Commonwealth as to be made the site of a small block-house, the ruins of which still remain. The Killery harbour has been described under the head GALWAY. Small piers have been constructed from time to time, at costs varying from 100*l.* to 2000*l.*, at Killalla, Belmullet, Sallee, Tarmon, Bulls mouth, Achil Sound, Clare Island, Oldhead, Innisturk, and Bundurra.

The only navigable river in the county is the Moy. An extended system of inland navigation has been proposed [CONNAUGHT], but, as yet, there are no canals within the county.

In no part of Ireland has the want of good roads been more felt, or have their advantages been more fully exhibited than in Mayo. In 1802 there was no road whatever passable for wheel-carriages in winter through western Tyrawley and the entire of Erris, a tract equal in area to many of the inland counties, and the district about Ballina was very ill supplied with means of communication. Roads have now been constructed, partly by government and partly by grand jury assessments, through both these districts, the chief lines being from Castlebar to Belmullet through the centre of Tyrawley, and from Killalla and Ballina eastward by Swinesford towards the terminus of the Royal Canal. Other good roads, from Castlebar to Ballina by the Puntoon, and from Ballina by Crossmolina to Belmullet, have also been recently constructed. The district of Murrisk has also been opened by a new and excellent road from Westport to the head of the Killery harbour, where it joins the line of government road through Connemara. The western parts of Murrisk are still unprovided with sufficient means of communication, and part of the district lying along the base of the Slieve Partry mountains next to Loch Mask is altogether impassable for carriages. The champaign part of the county is in general well opened, the principal line of road being that which leads from Westport and Castlebar through Hollymount towards Tuam.

From the vicinity of the Atlantic and the quantity of wet surface exposed, the climate of the western districts is damp and ungenial. The level part of the country, having the protection of so great a barrier of mountain in the direction of the prevalent winds, and lying open towards the east and south, enjoys a climate as mild as most of the midland counties. From the remains of submarine forests on the

coast and the quantities of bog-timber found on the sides of the most exposed mountains in Murrisk and Erris, it would appear that trees formerly flourished throughout the western district, where it is found very difficult at present to rear plantations even in the most sheltered spots.

Geology.—The geological structure of Mayo resembles, in its general features, that of Galway, exhibiting an arrangement of primary and secondary rocks skirting a limestone basin. As usual, the champaign district and the field of limestone are co-extensive, the primary and secondary formations being confined to Erris and western Tyrawley on the north, and to Murrisk on the south. It has been remarked that in many of the western bays of Ireland the rock which forms the bed or bottom of the bay consists of the floetz limestone, while the projecting promontories situated to the north and south of each are composed of primary or transition rocks. This observation is strikingly illustrated in Clew Bay, where the sea reaches to the verge of the limestone plain between lofty promontories of primary rock on each side, the structure of the bottom of the bay being manifested by a multitude of limestone islands rising round its upper extremity. The eskers which occur throughout the limestone plain near Westport exhibit traces of a current setting towards Clew Bay. Near Loch Conn and Killalla they indicate a current running northward in the line of the Moy. The verges of the plain are, as is usual in similarly situated districts, traversed by numerous subterranean channels, remarkable instances of which occur at Cong, and in the courses of the rivers Ayle and Owenduff, the latter of which has a subterranean course of two miles near Shrule, where it forms the county boundary. The Mullinmore also, a stream descending from Nephin, runs underground for about three miles.

The southern half of Murrisk, embracing the Fumnamore, Partry, and Mulrea groups, belongs to the grauwacke series; towards the plain in the valley of the Ayle, a tract of yellow sandstone lies between the clay-slate of this formation and the floetz limestone. Patches of limestone also occur in some places in this valley. The northern division of Murrisk consists mainly of mica-slate with protrusions of granite and quartz, bordered along the north-western coast towards Clew Bay by a tract of old red sandstone, which rises again on the southern and eastern side of the opposite island of Clare, overlying the granite of which the nucleus of that island consists. Of the quartz protrusions in the mica-slate field of northern Murrisk, the chief is the peak of Croagh Patrick. The exterior ranges of the northern mountain district consist chiefly of old red sandstone interposed between the mica-slate of the primary field of Tyrawley and Erris and the floetz limestone of the champaign. This tract evidently belongs to the same formation which shows itself in the north-west of Murrisk and in Clare Island. It constitutes the southern portion of Corraun Achil, a portion of the range of Nephin Bay, and the entire group of Croagh Moyle, from which, sweeping northward between the base of Great Nephin and Loch Conn, it forms the boundary between the mica-slate field and the limestone of the valley of the Moy throughout the whole extent of Tyrawley. The mica-slate field, as it stretches northward, recedes, and near the coast constitutes but a small portion of the district about Broadhaven. The limestone tract has a corresponding extension in that direction, occupying the greater part of north-eastern Tyrawley, but nowhere reaching to the sea, from which it is separated by an extensive field of yellow sandstone and conglomerate reaching from the north-east of Erris to Killalla. Throughout the great mica-slate field, comprising all Erris, the Mullet, the island of Achil, and southern Tyrawley as far eastward as great Nephin, granite and quartz protrusions are of frequent occurrence, generally constituting the loftiest and most striking elevations of the different mountain-chains. Granite again rises on the opposite side of the valley of the Moy in the Slieve Donagh mountains over Foxford, supporting flanks of mica-slate as in the opposite range of Nephin. Throughout the primary district iron-ore is abundant, and bloomeries have been worked near Tallaghan bay and in the valley of the Moy. But are now given up from want of fuel. Indications of coal are said to have been observed in Slieve Carnon, and deposits of lignite occur near Westport, but at present there are no mining operations carried on in this county beyond the quarrying of slates. Marble

susceptible of a good polish has been raised in several parts of the barony of Murrisk.

Soil, &c.—The soils of the champaign tract are in general similar to those of other limestone districts: the best lie about Balla, Claremorris, and Hollymount on the south, and round Ballina on the north. Towards the Sligo and Roscommon borders the soil is light and moory; it is light also throughout the greater part of the tract bordering on Galway, but of a deep and rich quality near Cong and along the eastern shore of Loch Mask.

The tillage lands in the immediate neighbourhood of Westport have been for the most part reclaimed from a comparatively moory state; but more northward towards Newport the soil is naturally sweet, and produces large crops of the best oats. Throughout both mountain districts, north and south of Clew Bay, cultivation only occurs in detached patches. In Murrisk however and Tyrawley are good tracts of upland pasture which answer well for the breeding of young cattle, though not equal to the fattening of stock. The common fence throughout the north and west of the county is the dry stone-wall, or in the moory parts sod-ditches. In the central district and towards the borders of Galway sod-ditches and quickset-hedges are general, but wherever stones can be easily had, dry walls are preferred by the country farmers. The following table exhibits the sales of grain in the principal market-towns in the under-mentioned years. The oats grown in Mayo are of a superior quality, but the wheat is in general inferior to that of Galway:—

	Wheat. (tons.)		Oats. (tons.)		Barley. (tons.)	
	1826.	1835.	1826.	1835.	1826.	1835.
Newport	..	12	1,283	1,000	76	275
Castlebar	638	1,426	50	76
Claremorris	1,800	2,000
Ballaghaderreen	407
Ballyhamis	445
Ballinrobe	..	1709	153
Westport	600	1400	13,000	15,720	400	100
Ballina	..	23	3,688	7,609	193	142
Killalla	5,100	3,218	250	315

The coast fishery, which might be rendered very productive, gave occasional occupation, in 1836, to 3768 fishermen. The craft employed consisted of 4 half-decked vessels, 12 open sail-boats, and 677 row-boats. The principal fishing-bank on the north lies between Downpatrick Head and Broadhaven, at about 3 miles from the shore, in 30 to 45 fathoms water, where turbot, sole, cod, ling, haddock, and hake are taken. Between the Stags of Broadhaven (insular rocks in the offing of that bay) and the island of South Inniskea is another bank, in 18 to 30 fathoms water, on which the same fish abound. From 40 to 50 miles due west of Achil Head some fish are taken [GALWAY]; but this fishery, requiring vessels of a better sort than are here in use, has been almost wholly abandoned. Blacksod Bay and Clew Bay also contain extensive fishing-banks for turbot, sole, plaice, &c., and vast quantities of oysters and lobsters may be taken on the shores of both. The herring-fishery is chiefly prosecuted, in the season, near the mouth of the great Killery harbour.

The principal river fisheries in the county are those of the Moy, Ballycroy, and Newport rivers. The salmon-fishery on the first lets for 1500*l.* per annum; the others are preserved by the proprietors. In the Newport river salmon are in perfect order all the year round.

The condition of the labouring classes is somewhat better in the remote and thinly-inhabited tracts than in the plain. From 6*d.* to 8*d.* a day for 100 working days in the year is the average rate of wages in most parts of the county; but in some districts the working days do not average more than 30 in the year. There is much wretchedness among the peasantry of the north-eastern parts of the county; and although the people of the mountainous western districts, in years of ordinary productiveness, are rather better provided with the necessaries of life than the residents on the plain, they have occasionally, especially in Erris and Achil, been reduced to an extremity of distress scarcely ever experienced in any other part of Ireland, by failures in their crops.

There is a large number of resident gentry: of the nobility, the marquis of Sligo and Lord Oranmore are the only residents.

The manufacture of linens is carried on to a considerable extent by the country people: the cloth is generally sold green by the small manufacturers, and bleached in other counties. At Belclare near Westport are factories on a large scale for linen and cotton fabrics. There is also throughout the county the usual home manufacture of friezes and coarse woollens. In 1831 there were in Mayo 16 bleachers, 10 reed-makers, 1730 weavers, 5 brewers, 11 corn-dealers, 8 tobaccoists, 3 maltsters, 58 millers, and 154 coopers.

Mayo is divided into the baronies of *Erris* (half barony) on the north-west, containing only hamlets and villages: *Tyracley* on the north, containing the towns of Ballina, population (independent of the portion in Sligo) 5510; Killalla, pop. 1125; and Crossmolina, pop. 1481: *Gallen* on the north-east, containing the towns of Foxford, pop. 1068, and Swineford, pop. 813: *Castello* on the east, containing the town of Ballaghaderreen, pop. 1147: *Clanmorris* on the south-east, containing the town of Claremorris, pop. 1476: *Kilmaine* on the south, containing the town of Ballinrobe, pop. 2604, and the village of Shrule, pop. 507: *Carra* in the centre, containing the town of Castlebar [CASTLEBAR], pop. 6373, and village of Minola, pop. 450: *Murrisk* on the south-west, containing the town of Westport, pop. 4448: and *Burrishoole* on the west, containing the town of Newport, pop. 1235.

Castlebar is the only corporate town in the county: its charter bears date the 11th of James I. The corporation is now extinct.

Westport is a place of considerable commercial activity. The exports of corn, meal, provisions, and other agricultural produce, in 1836, amounted to 11,800 tons, of the value of 87,805*l.*: the imports in the same year, consisting principally of coals, iron, sugar, flax-seed, tallow, and salt, amounted to the value of 28,517*l.*

Ballina has also a large and increasing trade in agricul-

tural produce. The exports in 1836 amounted to nearly 9000 tons of corn and meal and 500 tons of provisions, of a value, including a small export of kelp, hides, and feathers, of 70,568*l.* The imports in the same year were to the value of 13,532*l.*

The exports from Newport in the same year amounted to the value of 2269*l.*, and consisted wholly of corn. There do not appear to have been any imports. In the same year the exports from Belmullet amounted to the value of 2940*l.*

Prior to the Union Mayo was represented by four members, two for the county and two for the borough of Castlebar. The representation is now limited to the two county members. In 1837 the constituency consisted of 1350 voters. The assizes are held at Castlebar; and quarter-sessions at Castlebar, Westport, Ballina, Claremorris, and Ballinrobe. On January 1, 1836, the police force of the county consisted of 7 chief constables of the first class, 2 second-class ditto, 46 constables, 203 subconstables, and 15 horse, the cost of maintaining which establishment amounted, for the year 1835, to 10,142*l.* 13*s.* 1*d.*, of which 4853*l.* 16*s.* 4*d.* was chargeable against the county. The total number of prisoners charged with criminal offences who were committed to the county gaol in the year 1836 was 1115, of whom 1002 were males and 153 were females. Of these 230 males and 11 females could read and write at the time of their committal, 306 males and 42 females could read only, 437 males and 65 females could neither read nor write, and of the remainder the instruction could not be ascertained. The district lunatic asylum is at Ballinasloe, in the county of Galway. The county infirmary is at Castlebar, and there are dispensaries in all the towns and large villages. In 1836 there were four newspapers published in this county, to which 50,925 stamps were issued during that year. There are seven barracks in the county, affording accommodation for 1200 men, but they are only partially occupied at present.

History, &c.—This county formed part of the grant made by King Henry II. to William Fitz-Adelm de Burgho about the year 1180. It would appear that the new possessor had very soon made a permanent settlement, as in the 24th year of the reign of King Henry III., the then king of Connaught made a journey to England to complain of the invasion of his territory by the family of the Burkes. The lord-justice of Ireland was on that occasion commanded to 'root out that unjust plantation, which Hubert, earl of Kent, had, in the time of his greatness, planted in those parts;' but the command was never acted on, Richard de Burgho having obtained a new grant of all Connaught after the death of O'Connor, the then king. There is very little known of the subsequent proceedings of the settlers until the period of the great rebellion succeeding the assassination of William de Burgho, earl of Ulster, in A.D. 1333. [BELFAST.] About this time Mayo was a county, as appears by a roll of the 49th Edward III., preserved in the chancery of Ireland. It fell away however from all subjection to the English law immediately after the murder of the earl; for some of the younger branches of the Burke family, seeing that the entire province of Connaught would be inherited by his infant daughter (who afterwards married Lionel, duke of Clarence, and so gave the crown its title to the inheritance in the person of Henry VII.), seized upon the counties of Galway and Mayo, and, to avoid the consequences of their usurpation, not only cast off all allegiance to the English law, but renounced their English names and habits, identifying themselves and their followers in all respects with the native Irish. The name chosen by Edmund de Burgho, who seized on Mayo, was MacWilliam Oughter, or MacWilliam 'the farther,' to distinguish his

family from that of MacWilliam *Eighter*, or 'the hither,' who had in like manner usurped Galway.

All the followers of the family in the county followed his example. The D'Exesters, or D'Exons, took the name of MacJordan; the Nangles, or family of De Angulo, took that of MacCostello; and of the inferior families of the De Burghos, some took the names of MacHubbard, MacDavid, MacPhilben, &c. From this time till the reign of Queen Elizabeth the MacWilliam of the day continued to exercise the authority of an independent potentate. Many families from Galway and Ulster put themselves under the protection of the successive chiefs, and it is probably to this period that the first introduction of many of the most prevalent names at present in the county—Blake, Brown, Kirwan, Macdonnell, &c.—is to be referred. The first step towards a return to English law and manners was made in 1575, when the then MacWilliam, accompanied by the O'Malley and a number of the clan Donnell, came to Galway and made his submission, consenting to pay 250 marks per annum for his country, and to allow his followers to hold by English tenure. This chieftain is described by Sir Henry Sidney, who received his submission, as unable to speak English, though conversing fluently in Latin. The county was shortly after again declared a free ground. The Burkes however soon began to rebel under the new government, and, after many complaints, broke into rebellion, in which they were joined by the clan Donnell, Joyce, and other families in the south of the county. To appease these tumults Sir Richard Bingham marched to Ballinrobe on the 15th July, 1586, and having razed several castles of the Burkes and Macdonnells, and given the rebels, who had been joined by a body of 2000 Scottish islanders, a

signal defeat at Ardarae, on the Moy, succeeded in restoring the county to tranquillity. The old families of Mayo, in general, took part in the rebellion of 1641 and the succeeding wars, and very extensive forfeitures were the consequence. The forfeitures consequent on the war of the Revolution extended to 19,294 acres, of an estimated total value, at that time, of 37,398*l.* 3*s.* The families of Burke, Browne, and Dillon were those chiefly affected. During these troubles however Mayo was not the scene of any military operations of importance; the only memorable event of that kind, since the battle of Ardarae, being the invasion, by the French, under General Humbert, in 1798. The invading force consisted of 1100 rank and file only; but such was the alarm caused by their unexpected descent, that they easily carried the towns of Killalla and Ballina; and, being joined by a large body of the peasantry, defeated General Lake, at the head of 6000 men, before the town of Castlebar. [CASTLEBAR.] The surrender of the invading force at Ballinamuck however soon restored tranquillity. [LEITRIM.]

The antiquities of the county are chiefly ecclesiastical. There are round towers at Killalla, Turlogh, Meelick, and Balla. At Cong are the remains of a splendid abbey, originally founded in the seventh century, and re-edified by O'Connor in the twelfth. An archiepiscopal crozier of surprisingly beautiful workmanship, made by command of Turlogh O'Connor, the father of Roderick, the last native king of Ireland, and preserved at Cong until very recently, is now in the possession of the Royal Irish Academy. At Ballyhaunis are the ruins of a largely endowed abbey founded by the family of Nangle. Very fine remains of a Franciscan friary at Moyne, founded by William de Burgho, are still standing. Rosserk abbey, in the same neighbourhood, built by the Joyces in the fifteenth century, is another very striking ruin. Rathbran, also near the Moy, but of which all traces have now disappeared, was a foundation of the Jordans, the remains of whose castles are very numerous throughout the barony of Gallen. The remains of Ballintubber abbey, seven miles from Bullinrobe, are among the most elegant specimens of early architecture in Ireland. It was founded by Cathal O'Connor about the latter end of the twelfth century. Numerous other remains of religious houses founded by the families of De Burgh, O'Malley, and Nangle, throughout the county, are enumerated.

The military antiquities are not in general of much extent or interest. Carrig-a-Nile, near Newport, is said to have been a stronghold of Grace O'Malley, a daughter of that MacWilliam who submitted in 1575, still commonly known in Ireland by the name of Giana Naile, and celebrated for her exploits against the English, especially by sea. Doona Castle, on the shore of Tullaghan bay, was another seat of the O'Malleys, and is still a place of considerable extent: so also is Inver Castle, on the shore of Broadhaven, which probably belonged to the same family. On a detached rock, near Downpatrick Head, are the remarkable ruins of Doonbriste, or 'Broken Castle,' so called from certain remains of an ancient building on the cliff, corresponding exactly with other ruins situated on the summit of a detached rock, standing in the sea about 300 yards off, which is hence inferred to have parted from the mainland in some convulsion of nature. None of the other feudal remains are worth notice.

The county expenses are defrayed by grand jury presentments. The amount levied in 1835 was 27,051*l.* 14*s.* 7*d.*, of which 6003*l.* 14*s.* 1*d.* was for repayment of government loans, 5565*l.* 7*s.* 9*d.* for police, 9457*l.* 9*s.* 6*d.* for public institutions, and salaries, &c., and 6025*l.* 3*s.* 2*d.* for the construction and repair of roads and bridges.

MAYOR. [BOROUGH OF ENGLAND AND WALES.]

MAYOW. [CHEMISTRY.]

MAYPU. [CHILE.]

MAZANDERAN. [PERSIA.]

MAZARIN, Cardinal. [ANNE OF AUSTRIA; LOUIS XIV.]

MAZEPPA, Hetman (that is, commander-in-chief) of the Cossacks of the Ukraine, has become celebrated by a poem of Lord Byron, which has for its subject his extraordinary adventure. He was the son of a Polish gentleman in Podolia, and served for some time as a page of the court of King John Casimir (who reigned 1648—1688), where he

P. C., No. 916.

acquired some education. On his return to his native province he carried on an intrigue with the wife of one of his neighbours. Being surprised by the offended husband, he was bound by his orders, according to the current story, to one of those wild horses which roam in a half savage state about the Ukraine, and the animal was turned loose. The frightened horse ran with his unwilling burden, till it reached the country of the Cossacks, where Mazeppa, who was in a senseless state, was released from his dangerous position. Being restored to health by the kind treatment of the Cossacks, he entered into their service, and rose by degrees to the rank of their supreme commander. This romantic story of the horse seems scarcely credible, and one might reasonably doubt if a man could escape with his life under such circumstances. The point has at last been settled in a satisfactory manner by the contemporary memoirs of Passek, which were lately published in Polish. According to that author, Mazeppa was bound by the offended husband to the same horse on which he had come to pay his addresses to the wife. The horse, being let loose, carried its master back to his own house, and the shame which Mazeppa felt at having been exposed in such a manner induced him to leave his native land and retire among the Cossacks. Whatever may have been the reasons which induced Mazeppa to take that step, he soon distinguished himself by his bodily strength, great courage, natural abilities, and some acquirements, so that he became general-adjutant and secretary of Hetman Samoilowich, and after his death in 1687 was chosen to fill his place.

The Cossacks of the Ukraine, who were organised by King Stephen Battory (who died in 1586), rebelled against Poland in 1648, and being unable to maintain themselves as an independent nation, they submitted to the czar of Muscovy in 1654, on condition that all their liberties and privileges should be preserved. But the Muscovites soon began to encroach on their liberties, and attempted to convert the Ukraine into a province and govern it like the other parts of their empire. Mazeppa, who was much in favour with Peter the Great, to whom he had rendered many eminent services, was strongly attached to the liberties of his adopted country, and is said to have made strong but useless representations against their violation. The victories of Charles XII. of Sweden induced Mazeppa, notwithstanding his great age, for he was then about seventy, to enter into a negotiation with him for the independence of the Ukraine, which Charles promised to establish if Mazeppa would join him with his forces. The negotiation was discovered by two colonels of the Cossack army, named Iskra and Koczubey, who reported it to Peter the Great. Peter was however so confident in Mazeppa's fidelity, that he gave up both the colonels as calumniators to Mazeppa, who ordered them to be beheaded.

According to his agreement with Mazeppa, Charles turned from the high road to Moscow, which he was pursuing, to the south, in order to join Mazeppa and spend the winter in the rich Ukraine, but the disasters which befell his army on a march during the severe winter of 1708-9 reduced it to a wretched condition; whilst the designs of Mazeppa being discovered, his capital, Baturin, was taken, after a desperate resistance, by the troops of Peter, and Mazeppa, being deserted by his army, joined Charles with an inconsiderable force. After the battle of Pultava he retired with Charles to the Turkish territory, where he died soon after.

MAZZUOLI. [PARMIGIANO.]

MEACO, or KIO. [JAPAN.]

MEAD, RICHARD, M.D., was born near London in 1675, and after studying in some of the most celebrated of the continental schools, took the degree of Doctor of Medicine at Padua in 1695. On his return to England, obtaining considerable reputation in his practice, he was appointed in 1703 physician to St. Thomas's Hospital, and in 1711 anatomical lecturer at Surgeons' Hall. He was also elected a Fellow of the Royal College of Physicians, and was physician to George II. On the death of his chief patron, the celebrated Dr. Radcliffe, Mead became the most renowned physician of the day, and was obliged to relinquish all his public offices. He employed the greater part of the wealth which he obtained from his practice, in the patronage of science and literature, and in collecting pictures, and a very valuable library, of which he bequeathed the greater part to the College of Physicians. He died in 1754.

Mead's principal works are, 'A Mechanical Account of

VOL. XV.—F

Poisons,' London, 1702; 'De imperio solis et lunæ in corpora humana, et morbis inde oriundis,' 1704; 'A short Discourse concerning Pestilential Contagion,' 1720, which was written at the request of the secretary of state, in reference to the contagious nature of the plague then raging at Marseille, for the prevention of which Mead recommended the most rigorous measures of quarantine and disinfection. Some papers on Grecian coins struck in honour of physicians, from which he inferred many interesting facts in the history of medicine, and on which he had a long discussion with Dr. Conyers Middleton. 'On the Scurvy,' 1749; this was published as an appendix to the account of the method of ventilating the holds of ships then lately invented by Sutton. 'On Small-pox and Measles,' 1748; containing a full account of inoculation, of which he had witnessed the first experiments in this country on some condemned prisoners. 'Medicina Sacra, seu de Morbis insignioribus qui in Bibliis memorantur,' 1748; 'Monita et Præcepta Medica,' 1751, containing a general summary of his medical experience. All these works, both individually and collectively, passed through several editions in this country, as well as in Germany, France, and Italy.

(*Authentic Memoirs of the Life of Richard Mead*, by Matthew Maty, M.D., 8vo., London, 1755.)

MEADOW SAFFRON. [COLCHICUM.]

MEADOWS are properly low grounds on the banks of rivers, which, being kept moist by their situation, and also occasionally flooded by the rise of the waters, are best adapted for the growth of grass, and are generally mown for hay. Some meadows of great extent, belonging to a community or district, in which every inhabitant has a right to send his cattle to graze, under certain regulations, are never mown.

When the number of those who have a right of common pasture is not very great, they frequently agree among themselves to abstain from depasturing the meadows in spring, and, dividing them into portions, each makes hay of his share; after which the cattle are admitted in common for the remainder of the season. Thus a common meadow is converted into a *Lammus meadow*, that is, a meadow which becomes a common pasture after the 1st of August, this being the time when it is supposed that all the hay has been made and secured.

When meadows are private property they become much more valuable. The flooding is encouraged or prevented, according to circumstances, and in many cases artificial irrigation is adopted. [IRRIGATION.] If they are exposed to be too often inundated, they are protected by dams and sluices.

The herbage of low wet meadows is generally coarser and less nutritious than that of those which lie higher: hence upland hay, as it is called, is preferred for the better sort of cattle. Good grass land, to which the floods never rise, is often called meadow land when the natural herbage is permanent, and frequently made into hay.

Upland meadows are very valuable wherever there is a demand for good hay. A considerable degree of attention is required to make them most productive. Not being annually recruited by flooding, they would soon degenerate if some pains were not taken to keep up their natural fertility. This may be done in various ways: the most obvious is to recruit them frequently with the richest animal and vegetable manure, which, being spread over the surface at a time when showers are abundant, that is, either early in spring or immediately after midsummer, is washed down to the roots of the grass. A rapid growth is thus produced, which is soon perceived by comparing the appearance of a meadow which has been manured with that of one left in its natural state. It has been asserted by many agricultural authors that the produce of hay is greater when the meadows are mown every year, provided they be occasionally manured, than when mown and depastured alternately. But the productiveness of a meadow depends entirely on the circumstances of soil and situation. A meadow, the soil of which is naturally of a rich nature, and adapted to produce fine grasses, may be mown year after year without any perceptible change in the quality of the hay; while another of inferior quality requires to be occasionally cropped close, to check the growth of the coarser grasses, and to allow the finer to rise. As to the effect of taking off the hay by mowing it, compared with that of the bite of cattle, there is little difference, except that in pasturing the grass is repeatedly cropped close to the ground as soon as it

rises to such a height that the teeth of the cattle can sever it. It consequently spreads by the roots, and the pile becomes closer. The urine of the cattle greatly promotes luxuriant vegetation in rainy weather, but in hot dry weather it does more harm than good. The dung, when dropped on the grass, is of little or no value compared with what it would be if mixed up with straw, earth, or peat, or diffused through water in a tank. It is therefore an excellent practice to employ women and children to collect the fresh dung in the pastures, and to carry it to a heap of earth where it may be covered up, or to a tank where it may be diluted with water.

Of late years the practice of *soiling* has been extensively adopted; that is, all the grass is mown and carried every day, in a green state, to cows or horses tied up in a stable. By this means all the advantage of mowing for hay is obtained, besides an abundant supply of rich manure, which can be applied to the land in a liquid and diluted state, when its effect is powerful and certain. So much more fodder is produced from the land by the system of soiling, that arable fields are converted into artificial and temporary meadows, in which the different species of grasses are sown, in order to be cut green or made into hay; and when, from the nature of the soil, the herbage degenerates, the field is ploughed up again, greatly improved by this change of cultivation. [GRASS LAND.]

When a natural meadow has been neglected, and the grass is of an inferior quality, and mixed with rank weeds and moss, it requires much care to restore it to its original fertility. In most cases the shortest method and the best is to plough it up, clean and manure it during a course of tillage, without taking very exhausting crops from it, and then to lay it down again in a clean and enriched state, by sowing the best sort of grass seeds; or, which is preferable, by inoculating, or planting in it small tufts of grass from some rich meadow, which will soon increase, and produce a new and improved sward. But where the soil is a very stiff clay, with only a small depth of good mould over it, there is some danger in breaking the old sward, for it will take a long time and much manure to reproduce a proper covering of grass. In this case it is a preferable practice to scarify the meadow, by means of instruments which do not go deep, but only tear up the surface. If this is done early in spring, when the ground is moist, and the whole surface is brought to resemble a fallow field, good grass seeds may be immediately sown. If rich manure, mixed with lime or chalk, is then spread over the land, and the whole well harrowed and rolled, the old and young grass will spring up together, and show a wonderful improvement in a very few months. It is prudent to mow this renovated meadow before the seeds of the grasses are formed, contrary to a common notion that in a thin meadow the seed should be allowed to shed, in order to increase the number of plants. The notion is good, but it should be done by sowing seed produced on other ground: for the ripening of the seed tends to exhaust the soil. If the grass be cut before the flower is faded, the roots will soon spread, and produce a new and improved sward.

It must be observed that it is not indifferent what cattle are turned into the meadow after hay-making. Horses invariably produce coarse weeds by their dung and urine; cows may be depastured in autumn, as long as the surface is dry; but sheep are far more advantageous, and may be kept in the meadows at all times, if they are not too wet for the health of the sheep, and if there is no danger of their having the rot. As soon as the surface becomes soft by the autumnal rains, all heavy cattle should be excluded: every tread of a horse or cow at this time destroys a portion of good grass, and makes a hollow, in which the water remains, killing the finer grasses, and producing rushes and aquatic plants.

The meadows which are to be mown should be shut up early in spring, and those which are soft and wet should have nothing larger than a sheep in them from November till after hay-making time the next year.

MEAN. By the mean of two or more quantities is meant an intermediate quantity determined by mathematical rules. There are more ways than one of finding a mean, but the two principal results of this kind are called the *arithmetical* and the *geometrical* means. The names are not properly expressive of the distinction between them, but they are established by use.

An arithmetical mean is the simple AVERAGE, formed by

adding the quantities together, and dividing by the number of quantities. A geometrical mean is the square root of the product of the quantities. Generally, let there be a number of quantities, $x_1, x_2, x_3, \&c.$, and let $\phi(x_1, x_2, x_3, \&c.)$ be a function of them which is symmetrical, that is, which is not altered when any two of them are interchanged; then if y be found from the equation

$$\phi(y, y, y, \&c.) = \phi(x_1, x_2, x_3, \&c.),$$

y may be called a species of mean.

The arithmetical mean, or average (which is always to be understood when the word mean is mentioned, unless the contrary be specified), is taken to be the most probable result of a number of discordant quantities, which would have been the same but for errors of observation or experiment. Thus if three measures of the same length give 122, 123, and 123.4, the mean of which is 122.8, it is presumed that 122.8 is more likely to be the real length which was attempted to be measured than any other. We confine ourselves in the present article to pointing out how it may be ascertained what degree of probability belongs to such results.

In assuming the average as the most probable result, it is presumed that any one measurement is as likely to err one way as the other; that is, as likely to be too small as too great. If nothing but results be known, this presumption is justifiable; but if it be known that there is more tendency to error of one sort than the other, the most probable result cannot be ascertained until it is found out by how much the average of a very large number of observations would be affected by this tendency. Say it is known that in the long run the average will be increased .3 above the truth by a greater tendency to measure too much than too little; then $122.8 - .3$, or 122.5, is the most probable result of the preceding three observations.

It is obvious that when observations nearly agree with each other, the average must be nearly the truth required, and the nearer the agreement of the observations, the more nearly. If the observations do not agree well, the average is still more likely than anything else, but not so likely as before.

We now show how, having a number of observations, to determine the probability that the truth lies within a given degree of nearness to the average. A table must be used, which we here give to a greater extent than we should otherwise do, on account of succeeding articles. Let M be the average of a number of observations, and let $M + m$ and $M - m$ be the limits of which it is required to know what is the chance of the truth being between them. Take the difference between M and each of the results of observation, and add the squares of these differences. Multiply 100 times the number of observations by m , and divide by the square root of twice the sum just found: take the number nearest to the result in the column marked A, and opposite to it, in the column marked B, will be found the number of chances out of 10,000 for the degree of nearness required.

A	B	A	B	A	B	A	B	A	B	A	B

Suppose, for example, that seven observations give 10.03, 10.71, 10.98, 10.26, 10.30, 10.72, 10.81, the average of which is 10.54, differing from the respective observations by .51, .17, .44, .28, .24, .18, and .27, the sum of the squares of which is .7239, twice which is 1.4478, the square root of which is 1.203. Let it be required to find the chance of the truth lying between $10.54 + .06$ and $10.54 - .06$, we have then to multiply 700 by .06, which gives 42, and to divide by 1.203, which gives 34.9. Opposite to 35 in the column A is found 3794, so that 3794 out of 10,000, or 3794 to 6206 is the chance of the result lying between the limits given: that is, nearly 31 to 19 against it. If the limits proposed had been $10.54 + .1$ and $10.54 - .1$, 700 multiplied by .1 and divided by 1.203 would have given 58.2. Opposite to 58 in the table we find 5879, so that it is 5879 to 4121, or about 59 to 41, in favour of the result lying between 10.64 and 10.44.

In the preceding rule it is supposed that all the observations are equally trustworthy, or that there is no circumstance which would beforehand lead us to suppose that any one is more likely to be true than another. If this be not the case, no rule can be applied except one which depends on the observer's judgment. He must make the different observations reckon as different numbers of observations, allowing any one observation to count as more than one, if he believes it to be better than the rest. Thus suppose three observations to give 26, 28, and 29, and that it is thought there is reason to prefer 28 to the others, and 29 to 26, so that 28 ranks in the observer's mind as being as good as a mean of eight observations, 29 of six, and 26 of four. It must then be considered that there have been $8 + 6 + 4$, or 18 observations, of which 8 have given 28, 6 have given 29, and 4 have given 26. These numbers, 8, 6, and 4, are called the *weights* of the several observations, 28, 29, and 26, and the alteration in the preceding rule is as follows:—In forming the average, multiply each observation by its weight; add the result, and divide by the sum of the weights. Thus $8 \times 28 + 6 \times 29 + 4 \times 26 = 592$, which divided by $8 + 6 + 4$, or 18, is 27.89, the most probable result. In finding the probability of the truth lying within given limits on one side or the other of this most probable average, let the average be M as before, and the limits $M + m$ and $M - m$; take the difference between M and each of the results of observation, multiply the square of each difference by the weight of its observation, and add the results. Multiply 100 times the sum of the weights by m , and divide by the square root of twice the sum just found; take the number nearest to the result in the column marked A, and opposite to it in the column marked B will be found the number of chances out of 10,000 for the degree of nearness required. Thus if in the preceding instance we ask what is the chance of the truth lying between $27.89 + .2$ and $27.89 - .2$, we observe that 27.89 differs from the several results by 1.89, .11, and 1.11, the squares of which multiplied by 4, 8, and 6, and the results added together, give 21.7778, twice which is 43.5556, the square root of which is 6.600. And 100 times the sum of the weights, or 1800, multiplied by .2, is 360, which divided by 6.6 gives 54.6. Opposite to 55 in column A we find 5633; in column B; that is, we have 5633 to 4367, or about 55 to 44 in favour of the truth lying between the limits specified.

The inverse problem is as follows: given the observations, required the limits of difference from the average between which it is a given chance, a to b , that the truth shall lie. In both cases the first process is to turn $a:(a+b)$ into a decimal fraction of four places, and to take the numerator of such fraction.

Look for the numerator in column B, find the number nearest to it, and take out the number corresponding in column A. Multiply this by the square root used in the direct rule, and divide by 100 times the number of observations, or, if they are not equally good, by 100 times the sum of the weights. The quotient is the answer required. But when, as most frequently happens, an even chance is the given chance, use 47.7 instead of the number found in column A.

In the first of the given instances it is required to know within what limits it is 99 to 1 that the truth is contained. Here 99:(99+1) is .9900, and looking for 9900 in column B we find 9899 opposite to 182 in column A. Multiply 182 by 1.203, which gives 218.946, which divided by 700 gives .313, so that it is 99 to 1 that the truth lies between $10.54 + .313$ and $10.54 - .313$.

In the second instance, required the limits within which it is an even chance that the truth is contained. Multiply 47.7 by 6.6, and divide by 1800, which gives .175; and it is an even chance that the truth lies between $27.89 + .175$ and $27.89 - .175$.

The amount of departure from the average within which, on one side or the other, it is an even chance that the truth shall lie, is called the *probable error* of the observation or average of observations to which it refers. When the probable error of any one observation is given, that of the average is found by dividing it by the square root of the number of observations. Thus if there be 100 observations, of each of which it is an even chance that it is within .1 of the truth; then the square root of 100 being 10, and $.1 \div 10$ being .01, it is an even chance that the average of the hundred observations is within .01 of the truth.

For further account of the matters contained in this article, see *PROBABILITIES, THEORY OF; OBSERVATION; RISK*. For description of methods without demonstration, see Lardner's 'Cabinet Cyclopædia,' Essay on Probabilities. For demonstration, see the works of Laplace or Poisson on Probabilities, the article 'Probabilities' in the 'Encyclopædia Metropolitana,' or Mr. Galloway's article on the same subject (published separately), in the 'Encyclopædia Britannica.' The table may be found to greater extent in the first and two last articles cited, and also in the Berlin 'Astronomisches Jahrbuch' for 1834.

MEANDRI'NA, a genus of Lamelliferous corals. [*MADREPHYLLEA*.]

MEASLES (*Morbilli, Rubeola*) is the popular name of a contagious disease, characterised by an eruption on the skin, and affecting chiefly children.

The etymology of the word measles is uncertain, but its application to the disease we are treating of was probably borrowed from an appearance so denominated in pork, to which the eruption bears resemblance. Measles is ushered in by more or less fever, a running from the nostrils and eyes, with some inflammation of the latter, sneezing, hoarseness, a dry cough, difficulty of respiration, and occasionally slight soreness of the throat. From three to six days after the commencement of these symptoms a rash begins to appear, which first shows itself in distinct, red, and nearly circular spots, having some resemblance to flea-bites: these spots gradually coalesce and form small slightly elevated patches of an irregular figure, but approaching nearest to that of semicircles or crescents. The patches first show themselves on the forehead and face, and gradually extend downwards to the trunk and extremities. At the commencement of the eruption the catarrhal symptoms and fever are somewhat augmented, and during its height the whole face is often swollen and the eyelids thereby closed; on its decline, which begins on the fourth or fifth day, the fever ceases, and from those parts of the body previously covered by eruption the cuticle separates in small bran-like scales. A diarrhoea now commonly supervenes, and affords relief to the other symptoms. This however is the period when the danger, which is a consequence rather than a concomitant of measles, commences. The cough, which has continued throughout the active period of the disease, now assumes a more serious character; the expectoration, which hitherto has been simply mucus, indicative of the inflammation being confined to the mucous membrane of the bronchial tubes, becomes bloody, or mixed with pus, showing either that inflammation has attacked the proper substance of the lungs, or that tuberculous deposits have taken place in these organs, constituting pulmonary consumption. If the patient happily escape these dangers, others, less fatal indeed, but scarcely less to be dreaded, not unfrequently show themselves, among the most severe of which are obstinate ophthalmia and inflammation of the internal parts of the ear, the former not unfrequently terminating in partial or total loss of vision, and the latter in deafness. It must be confessed however that this is a picture, rather of what may and occasionally does happen, than of what takes place in the majority of instances; such severe terminations of the disorder are confined chiefly to the ill-fed and ill-clad children of the poor, and to the more sickly ones of the opulent. Measles frequently occurs as an epidemic, in this country usually at the beginning of spring. These epidemics vary considerably in character, being sometimes benign, at other times very fatal, and occasionally they are observed to prevail in conjunction with small-pox; like the latter disease, measles rarely attacks the same individual twice. Experiments

have been made to determine how far inoculation with the blood of the parts on which the eruption appeared might succeed in moderating the violence of the disease thus artificially produced; but the cases in which it was tried were not sufficiently satisfactory to warrant its general adoption. Measles, before the outbreak of the rash, may be mistaken for severe catarrh; the eruption itself is liable to be confounded with that of Roseola, Scarlatina, Strophulus, Lichen, Urticaria, incipient small-pox, &c.; but the crescentic shape of the patches and the catarrhal character of the other symptoms can hardly fail to remove any doubt as to the nature of the disease. With respect to the treatment, little is required during the eruptive stage of the disorder, which is seldom attended with danger. It is chiefly necessary to open the bowels, to confine the patient to a light vegetable diet, with cold acidulated aqueous drinks, and to maintain a cool temperature in the room, which should be moderately darkened. Where the skin is dry and hot, sponging it with cold water has been recommended and practised with benefit. The old practice of confining the patient in heated chambers, and covered with an overwhelming quantity of bed-clothes, is now justly abandoned: the free use of the lancet during the eruptive period of the disease is likewise laid aside, and its employment restricted to those cases in which any of the vital or important organs are threatened or attacked by inflammation. Should this take place, blood-letting by lancet, cupping, or leeches, aided by blisters and such medicines as act most efficaciously in reducing inflammation, must be had recourse to. Cases in which the vital powers are low, to which the name Rubeola Putrida has been applied, of course will require an opposite mode of treatment, as the exhibition of bark, the mineral acids, and wine, together with a nutritious diet and a pure atmosphere: these too are the remedies which prove most serviceable in checking the diarrhoea, if injuriously protracted.

MEASURE. One number or magnitude is said to measure another, when the first is contained an exact number of times in the second. [*INCOMMENSURABLE; PROPORTION*.]

MEASURES. [*STANDARDS; WEIGHTS AND MEASURES*.]

MEATH, formerly distinguished as **EAST MEATH**, an Irish county in the province of Leinster; bounded on the north by Monaghan, on the north-east by Louth, on the east by the Irish sea, on the south-east by the county of Dublin, on the south by Kildare, on the south-west by King's County, on the west by West Meath, and on the north-west by Cavan. Its form is very irregular. Its greatest length is from the coast of the Irish Sea near Gormanstown on the east, to the bank of Lough Sheelin, or Shillin, on the west, 47 statute miles; its greatest breadth, at right angles to the length, is from the border of the county of Monaghan on the north, to the junction of the three counties, Kildare, King's County, and Meath, on the south, 39 or 40 miles. The area of the county of Meath is estimated at 488,758 statute acres, or nearly 764 square miles.* The population by the census of 1831 was 176,826, giving 231 inhabitants to a square mile. In size it may be compared with the English county of Westmoreland; in amount of population, with Northampton; and in density of population, with Durham. Trim, the assize town, is about 25 miles north-west of Dublin.

Surface; Coast-line; Geological Character.—The loftiest elevations are in the western part of the county, just to the south of the Cross-Water stream, which separates this county from Cavan. The principal hill is Shebh-nallagh, near the village of Loughcrew, between Old-castle and Crossakeel. There are considerable elevations also in the north-east part of the county, on the north bank of the Boyne about Slane and Newtown Fortescue. Various other parts of the county are hilly, but not so much as the districts just mentioned. (*Maps subjoined to Irish Railway Commissioners' Second Report; Population Returns.*)

The coast has a tolerably straight outline running south by east from the mouth of the Boyne to the boundary of the county of Dublin near Gormanstown. The shore is low, skirted by sand-banks or hills, and broken by one or two small streams which flow into the sea.

The county of Meath is for the most part included in the

* We take this from the 'Parliamentary Returns.' The table given with Mr. Larkin's Map published by the grand jury of the county, A.D. 1817, makes the area 566,657 statute acres; and that subjoined to the Map of Ireland published by the Society for the Diffusion of Useful Knowledge, 575,413 acres.

great central carboniferous limestone district of Ireland; the whole of the southern part of the county, and considerable portions of the north and west, are occupied by this formation. The limestone districts are comparatively low and flat, as they usually are in Ireland, while in England they have, from their ruggedness and elevation, given to their component rocks the distinctive designation of mountain limestone. A part of the Meath limestone-beds belongs to the calp or black shale series, composed of alternations of impure black argillaceous limestone with black shale containing balls of grey ironstone. From beneath the beds of the calp series, those of the lower limestone crop out. It is probable that from beneath these the lowest series of the carboniferous limestone beds are found cropping out near the limits of the limestone district; this lowest series consists chiefly of a yellow sandstone, sometimes interstratified with dark-grey shale and dark-grey limestone; in some localities it contains very thin beds of impure coal.

The hilly parts of the county belong to the transition district, which extends from the coast of the county of Down into the counties of Longford and Roscommon. The rocks of this district are greywacke-slate, fissile clay-slate, flint-slate, and chlorite-slate. A small tract, insulated in the midst of this transition district, is occupied by the rocks of the limestone formation already described, and by a small coal-field, the beds of which rest upon the limestone. This coal-field is partly in the county of Monaghan, partly in that of Cavan, but chiefly in Meath. Many trials have been made, but no coal worth working has been found. (*Irish Railway Commissioners' Second Report, Appendix; and Geological Map.*) Limestone and marl are abundant.

Rivers.—The county belongs almost entirely to the basin of the Boyne; a small portion in the northern part of the county belongs to that of the Deo; the heights about Slane separating the two. The southern and south-eastern borders are watered by the alluents of the Liffey, or by some smaller streams which flow into the sea between the Liffey and the Boyne.

The Boyne touches the border of the county at its south-western extremity, and after dividing it for a few miles from the county of Kildare, passes within the boundary and flows in a winding channel north-east by Trim to Navan, where it receives the Blackwater, its chief tributary. The Menagh (which skirts the south-western border of the county till its junction with the Boyne at the spot where the latter first touches the border), the Blind, the Blackwater (which divides Meath on the south side from the county of Kildare), and the Deel, all small streams, join the Boyne before it receives the greater Blackwater. From the junction of the last, the Boyne flows east-north-east by Slane to the border of the county, and from thence along the border (separating Meath and Louth) into the sea at Mornington, below Drogheda. The length of that part of the Boyne which is in the county of Meath or upon the border is about 56 miles. It is navigable in the natural bed of the stream to above Drogheda (where it is crossed by a bridge), and afterwards partly in the natural bed and occasionally by a lateral cut or canal, to the junction of the Blackwater at Navan, about 23 miles from its mouth. The Blackwater touches the border of the county on the north-west side at the junction of the Crosswater, a small brook which, as well as the Blackwater itself, separates Meath from Cavan. The Blackwater soon quits the border and flows east-south-east, 18 miles, into the Boyne at Navan. It passes near the town of Kells. It receives a considerable stream, to which the maps give no name, from the border of the county near Moyonalty. The continuation of the Boyne navigation to Trim, and the making of the Blackwater navigable to Kells, would be of the greatest advantage to the county.

The Nobbor rises from some bogs and small lakes on the northern side of the county near Kilmainham; it flows in a winding course, first south-east, then north-east until it quits the county to enter that of Louth, where it unites with the Deo. Its length in this county is about 12 miles.

Lakes.—There are several small lakes. Lough Sheelin, which separates the counties of Meath and West Meath from that of Cavan, is of an oval form, 5 miles long from north-east to south-west, and about 2½ miles broad. It contains a small islet, called Church Island, with the ruins of an old church in it. Lough Bawn, 1½ mile long, but very narrow, and some smaller lakes, are on the western border of the county. The lake of Kilmainham, formed by an expansion of the river Nobbor, is about one mile long and

above a quarter of a mile broad. Bogs are numerous, but the aggregate of their extent is small: the largest bog is on the border of the county south-west of Athboy; it is partly in Meath and partly in West Meath. (*Railway Commissioners' Reports; Larkin's Map.*)

Canals, Railroads, and other Communications.—The Royal Canal enters the county near Kilcock (Kildare county), and runs for some miles just within the border, occasionally quitting it for the adjacent county of Kildare. It is carried by an aqueduct over the smaller Blackwater and by another aqueduct over the Boyne, soon after crossing which it enters West Meath. About 14 or 15 miles of this canal are within the county. It opens a communication with Dublin at one end, and the Shannon, near the town of Longford, at the other.

A railroad from Dublin to Drogheda, for which an act has been obtained, is to cross the county from south to north along the coast. The lines laid down by the government commissioners for the railroads from Dublin to Enniskillen and Armagh respectively also cross this county. They coincide in the first part of their course, entering the county on the south side near Dunboyne, about 8 miles from Dublin, and running from thence north-west about 20 miles to Navan. Here the lines separate; that to Armagh running north about 17 miles, till it enters the county of Louth; and that to Enniskillen continuing to pursue a north-western direction about 16 miles, till it enters the county of Cavan. Surveys have been laid before the commissioners for the following railway lines across this county. One from Dublin to Sligo and Galway crossing the county from Kilcock (county Kildare), nearly parallel to the Royal Canal, into the county of West Meath. A branch from this by Trim passes to the Enniskillen line at Kells; and a branch from the Enniskillen line near Kells runs westward into the county of West Meath, joining the Sligo line at Longford. A line collateral to the Armagh line and to the east of it passes near Ratoath and Slane, and another line runs from Navan to Drogheda.

The principal coach-road is that from Dublin to Drogheda, Dundalk, Newry, and Belfast, with a branch to Armagh. From Dublin to Drogheda this road has two branches, one near the coast through Gormanstown, the other more inland. There are well frequented roads from Dublin to Virginia, Cavan, and Enniskillen, through Dunshaughlin, Navan, and Kells; from Dublin to Granard by Trim and Athboy, with a branch by Old Castle to Killyshandra; and from Dublin to Longford, Carrick on Shannon, and Sligo by Clonard, in the south-west part of the county. A considerable number of passengers travel by the Royal Canal from Dublin and Kilcock to Mullingar in West Meath. The principal roads for the conveyance of goods are from Dublin by Navan and Kells to Virginia; and from Drogheda (one of the principal ports of Ireland) by Slane to Kells, and by road to Navan. The land traffic on this latter line would probably be greater but for the communication between the towns of Drogheda and Kells by means of the navigation of the Boyne. There is considerable traffic also from Dublin to Trim and Athboy, and from thence to Oldcastle; also from Kells to Oldcastle on one hand, and to Baillyborough (county Cavan) on the other. (*Railway Commissioners' Second Report.*)

The county appears to be on the whole tolerably well provided with roads.

Soil; Agriculture; Condition of the People.—This county has very few mountain-wastes, and the proportion of bog is small. The land is for the most part flat rich pasture-land. There are a few fine domains, especially those of the marquis of Conyngham and of the Lambert family, near Slane, and that of the marquis of Headfort, near Kells; and there are many gentlemen's houses scattered through other parts of the county. The soil is for the most part a loam of the richest character, and in many places of such depth that the turning up of a fresh portion of the soil by ploughing deeper than usual is considered as an efficient substitute for manuring. In some baronies animal manure alone, or mixed with bog-stuff or peat, is chiefly used; in others 'marl-sand,' a valuable mixture of calcareous matter and alluvial deposit, is used; and also lime. The farms vary in size from 2 acres to 3000 acres, but are on the average larger than in most other parts of Ireland; the grazing farms average about 150 acres; and tillage farms 20 to 50. The mode of farming, though very slovenly and defective, bears some resemblance to that of England. Summer fallows,

though coming into disuse, have been considered necessary, owing to the rank luxuriance of the weeds. The rotation of crops in small farms is, usually, fallow or potatoes with manure; second year, wheat; third year, oats; and, frequently, fourth year, oats. Larger farmers sow clover the fourth year, which remains one year or more, and is followed by oats; a few sometimes grow barley instead of wheat the second year. The practice of growing potatoes as a preparation for wheat, instead of leaving the land fallow, is increasing. Flax is seldom grown in large quantities for sale, but small patches for domestic use are general: a strong kind of dowlas and some sheetings are made from it in the country. Turnips, mangel-wurzel, vetches, rape, grey and white peas, beans, and cabbages, are cultivated, but not generally; turnips are grown only by the wealthier farmers, who unite grazing with tillage, and are chiefly used for feeding sheep; cabbages succeed well, but the expense of transplanting, and the liability to depredation, are great objections to this crop. The whole quantity of land devoted to green crops is small, in consequence of the abundance of the natural pastures, which are of unequalled richness, and have led the farmers to give their chief attention to grazing. The growth of clover and vetches is however gaining ground.

The quantity of cattle fattened in the pastures of the county is considerable; but as the rent of land is too high to admit of its being used to breed stock, the cattle which the graziers intend to fatten are collected from various parts. The English long-horned breeds were introduced many years ago, and some of the best specimens in Ireland are to be found in Meath. The breeds most in request are the Durham 'short-horned' and the Hertford breed for fattening, and the Ayrshire for milch cows. After being bred, the cattle are turned out until they are fit for the butcher. The pastures are opened in May for grazing the stock designed to be fattened in the ensuing summer. The best-conditioned of the heifers, which are half fat, are put to the forwardest grass, and supply the Dublin market in June, July, and August, when beef bears the highest price. The season for slaughtering cattle to supply shipping with salt provisions commences in September, and after its commencement the graziers rely chiefly on the northern buyers, who purchase the cattle at the fairs in or near the county, and sell the beef for home consumption, or salt and barrel it for exportation.

Meath, in regard to the quality of its grazing land, is the first county in Leinster, and grazing is carried on on a large scale. Many persons fatten from 300 to 500 cows in a season, besides bullocks and sheep. Oxen are frequently employed in the plough.

On many farms the landlord supplies land, horses, and a succession of cows in milk; the tenant furnishes labour and utensils, and pays for making the hay used by the cows. The skim-milk is mixed with the butter-milk, and sold to the retailers of Dublin, who vend it to the poor. From December to May the dairy-cows are fed on hay, straw, or a mixture of both, and are housed at night.

There are large flocks of sheep kept by the more extensive farmers; the small farmers rarely keep any. A good deal of mutton is fattened, but few of the sheep are bred in the county. They are chiefly purchased at the fair of Ballinasloe (county Roscommon) in October; some of these are fed during the winter on rape and turnips, and are sold at Dublin in the spring; the rest are turned out into the pastures previously used for the summer stock of cattle, and are fed in addition with hay. In May and June, after shearing, or perhaps in July or August, they are fat enough for the Dublin market.

From the low price of corn and the rise of the value of wool and stock consequent on the more rapid and certain communication with England, grazing has been for some years increasing.

The horses are generally inferior. 'Every farmer who holds a hundred acres and upwards keeps one or two mares, which he breeds from, and works to within about a fortnight of the time of their dropping their foals: these he rears, and in the spring before they are three years old he either sells them in the halter or works them in his own team; from which time to the day of their death they lead a life of hardship, and often of starvation. Bad feeding and hard working in their youth prevent their growing to their full size.' A large, long, blood horse, which sells for a high price, is much reared in this county.

Pigs are of a good breed, and are nearly or quite as common as in most other parts of Ireland. Poultry is abundant and cheap. Bees are kept in several districts.

Draining appears to be better understood in Meath than in many other parts, though there is much need of its being further extended. Under-drains are constructed on a peculiar but efficient plan.

Wood is not abundant, ground being too valuable to be occupied by plantations, except about noblemen's and gentlemen's demesnes for the purpose of ornament. Plantations for this purpose are however numerous, and timber-trees are common in the hedge-rows. Oaks are scarce; the beech, elm, ash, sycamore, poplar, and alder are more plentiful. There are several nursery-grounds, especially a very extensive one near Navan. From the small extent of the bogs and the deficiency of wood, fuel is scarce, and the poor often suffer severely from the want of it. (*Wakefield's Account of Ireland.*)

The population is most dense in the northern and western parts of the county, where there are 200, and in one part (the barony of Morgallion) 240 inhabitants to a square mile. In the south-western parts, and around Slane, and on the coast, the proportion is about 170 inhabitants to a square mile. In the central and southern parts the population is thinner, varying from 110 to 140 persons to a square mile. The disproportion between the demand and supply of labour varies. In some parts there are no destitute poor, the residence of the proprietor furnishing employment, and the limitation or decrease of the number of cabins repressing the increase of population; but this absence of destitution in some spots is counterbalanced by the throngs of unemployed and destitute poor on the edges of commons and bogs, in poor villages, and in the suburbs of towns. In the baronies of Upper and Lower Kells, which are among the most densely peopled, from one-fourth to one-tenth (the proportion varying in different parishes) of the labourers are in constant work, about one-tenth are almost constantly out of employment, and the remainder are employed from two to eight or nine months in the year. Men's wages are about 10d. per day, except in winter, when they fall to 8d., and in harvest, when they rise to 1s. 3d. or 1s. 6d.; boys under sixteen years earn usually about 4d., in winter 3d., and at harvest 5d. to 8d.; women earn 4d. to 6d., and in harvest 6d. to 10d., but have no work at all in winter. Wages are not usually paid in kind, except to herds and shepherds, who have meal, potatoes, or grass for a cow or several sheep, to the amount of about half their wages. In harvest-time it is usual to pay the labourers partially in food. From low wages and insufficient food, combined perhaps with other causes, the peasantry are neither so skilful nor persevering in labour as the English. The cottiers generally keep a pig, though in many cases a pecuniary loss is incurred: the reason for this apparently unprofitable practice was shrewdly stated to the commissioners for inquiring into the condition of the Irish poor, by a peasant, who observed that 'his pig was his savings' bank; for that he was obligated to save every penny that he could to feed him, and he did not so much miss it a little at a time; and that it came in again all in a lump, when he sold him to pay his rent.' The wives of the labourers generally rear fowls, and they make a trifle by the sale of the eggs and chickens.

The only home manufactures are a little coarse linen, sometimes, though rarely, a little coarse frieze coating, and the knitting of coarse worsted stockings, which last branch of industry is still pretty commonly done by girls, widows, and old women, who earn at this work about 1s. 3d. a week. Spinning and weaving, from the cheapness of manufactured goods, have almost entirely ceased.

Potatoes form the chief food of the labourer: oatmeal is used in summer by those in good employment, and on some particular occasions they have an egg, a herring, or a morsel of bacon as a treat. Small farmers eat herrings, eggs, and butter; but no meat, except sometimes a little of their own bacon. The cabins of the peasantry are wretched. Of furniture they have scarcely anything: the master of the house (with his wife, if married) sleeps on a frame of rough wood, split poles, stout sticks, &c., raised off the floor by stone blocks or other supporters, and called a bedstead; the rest of the family sleep on the floor; the only bedding is straw rushes, or, in a very few cases of unusual luxury, a piece of coarse sacking tick filled with chaff. An old threadbare blanket, often full of holes, pieces of old carpet

with the day clothes of the family, form the night covering. The most miserable habitations are in the suburbs of towns and around bogs. Cases of bastardy are very rare, and incur general opprobrium; but this opprobrium falls too heavily and exclusively on the weaker party. Drunkenness is rare among the labourers and their wives; more frequent among the small farmers and tradesmen. (*Report of the Commissioners for inquiring into the Condition of the Irish Poor.*)

There is no return of the quantity of corn sold in the principal markets for the ten years last before 1836.

Divisions, Towns, &c.—Meath is divided into eighteen baronies, which, with their relative position, and population in 1831, are as follows:—

1. Deece, Lower	Central	3,931
2. Deece, Upper	S.	5,294
3. Demifore or Half Foure	W.	13,717

4. Duleek, Lower	E.	10,020
5. Duleek, Upper	E.	8,941
6. Dunboyne	S.E.	2,698
7. Kells, Lower	N.W.	13,666
8. Kells, Upper	N.W.	20,462
9. Lune	W.	12,212
10. Morgallion	N. and Central	11,990
11. Moyfenragh, Lower	S.	11,893
12. Moyfenragh, Upper	S.W.	8,631
13. Navan, Lower	Central	16,234
14. Navan, Upper	Central	4,837
15. Ratoath	S.E.	6,685
16. Skreen or Skryne	Central	8,683
17. Slane, Lower	N.	9,647
18. Slane, Upper	N.E.	7,265
Total		176,826

Population.

Date.	How ascertained.	Houses.	Families.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	Families not included in the preceding classes.	Males.	Females.	Total.
1792	Estimated by Dr. Beaufort	22,468	112,400
1813	Under Act of 1812	25,921	142,479
1821	Under Act 35 Geo. III., c. 120	27,942	30,125	79,778	79,405	159,183
1831	Under Act 1 Will. IV., c. 19	29,796	31,632	22,396	4,575	4,661	88,993	87,883	176,826

The towns are—the assize, market, and post town of Trim, the market and post towns of Athboy, Duleek, Kells, Navan, Oldcastle, and Slane; the post towns of Ashbourne, Clonard, Clonree, Crossakeel, Dunshaughlin, Enfield, and Nobber; and the ex-parliamentary borough of Ratoath.

Trim, Athboy, Kells, and Navan, and the village of Duleek, were all formerly parliamentary boroughs.

Trim is partly in the barony of Upper Navan, but chiefly in that of Lower Moyferagh, 32 English miles from Dublin. It is a very ancient town: on the conquest of this part of Ireland by the English, it was conferred, with the rest of the county, on Hugh de Lacy, who made it a free borough. His son Walter gave it a charter of incorporation: and as the head of the lordship of the De Lacys, it acquired importance, and several of the early Irish parliaments were held here. In the civil war of 1642, the Catholics who held it were expelled, and the Parliamentarians garrisoned it under Sir Charles Coote; but he being killed, the place appears to have been lost, for in 1649 it was held by a royalist garrison, which quitted it on the approach of Cromwell, intimidated by the massacre of the garrison of Drogheda.

The town is pleasantly situated on the river Boyne: many of the houses are neatly built, and the environs are pleasant. There is an old bridge over the river, and an ancient castle of venerable appearance; the keep, a massy pile strengthened by four round towers at the corners, is yet standing, as well as several of the outworks. The church is modern, except the tower, which is of great antiquity. There are some remains of an ancient abbey; and a handsome Corinthian column erected in honour of the Duke of Wellington.

The population of the town in 1831 was 3282; 400 of them Protestants, the rest Catholics: that of the outparts of the parish, which is extensive, was 2644: together, 5926. The place has been declining for years, and presents on the whole a very impoverished appearance. It has no extensive trade or manufacture; the principal traffic is with Dublin and Navan. The market, which is on Saturday, has increased: there are five yearly fairs. The assizes are held here, and the quarter-sessions for the division twice in the year. The county court-house and gaol are here. The town returned members to the Irish parliament, but was disfranchised at the Union. The corporation consists of a portreeve, burgesses, and freemen, who are all now members of the Established Church. The living is a vicarage, united to several other benefices, and the town is at the head of a Roman Catholic district or union. Trim is the head-quarters of the constabulary police, and the residence of the inspecting magistrate.

Athboy is in the barony of Lune, 7 miles north-west of Trim, and 36 from Dublin. It is an ancient borough: the municipality received a charter from Henry IV.; and Eli-

zabeth conferred on the place the elective franchise, which it lost at the Union. The corporation then fell into disuse, and is now extinct. The town has a population of 1959; the outparts of the parish (which is extensive) of 3358: together, 5317.

There are four fairs in the year. The town is the chief station of the constabulary force for the district: petty sessions are held weekly. There are extensive flour-mills, but the town is poor, and does not seem to be improving. The living is a vicarage attached to the union of Athboy; the parish is also the head of a Roman Catholic union. There are a dispensary, almshouses for twelve poor widows, and several schools.

Duleek is partly in the barony of Upper Duleek, but chiefly in that of Lower Duleek, on the Nany or Nanny-water. There were anciently three religious houses, of two of which the ruins yet remain; and the town was the seat of a bishopric, ultimately merged in that of Meath. There were, in 1831, 233 houses and 1217 inhabitants in the town; and 733 houses and 1190 inhabitants in the whole parish. There was formerly an extensive manufacture of ticking, but it is now much diminished. There is a market on Thursday, and there are four yearly fairs. Races are held in the neighbourhood. Petty sessions are held here, and the town is one of the stations of the county constabulary force. Duleek returned members to the Irish parliament, but was disfranchised at the Union, and the corporation became extinct. The parish is part of a union, both in the Established and Catholic churches. The parish church is a modern building: the Catholic chapel is a handsome Gothic edifice, and has a school-room adjoining. There are in the parish several public schools and a dispensary. There are in the town two stone crosses, and in the parish another elaborately carved.

Kells is in the barony of Upper Kells, nearly 40 miles from Dublin through Navan. It is a town of great antiquity, and, previous to the arrival of the English, had a monastery of regular canons. It was fortified by the English with a castle and walls. The monastery, which had been plundered, was endowed with new grants by Hugh de Lacy; and Walter de Lacy, son of Hugh, founded another monastery for Crouched friars. The town became flourishing, but the dissolution of the monastic establishments and the repeated wars which desolated the country caused its decay.

Kells is pleasantly situated on the south bank of the Blackwater. The principal street is very broad; the streets generally are well kept, and the town presents an appearance of neatness. The population of the town, in 1821, was 3618; in 1831 it had increased to 4326: the population of the whole parish was 6839. The market, which is held on Saturday, has so increased as to have rendered an enlargement of the market-place necessary. The quarter-sessions

for the division are held twice in the year at Kells, twice at Navan. There are a bridewell and a fever hospital. It is the station of a chief constable and fifteen others of the county constabulary police.

There is a corporation, consisting of a sovereign, two provosts, and twenty-four burgesses; with a recorder and other officers. The sovereign, the provosts, and a few of the burgesses constitute the common-council or managing body: they have no jurisdiction. Kells returned members to the Irish parliament from the time of Elizabeth to the Union. The parish is at the head of a parochial union, both in the Established Church and among the Catholics. The parish church is an antient building: near it is an antient round tower, unroofed, about 90 feet high. There are two fine old crosses, one in the church-yard and one in the street near the market-place; also an antient stone roofed cell or chapel.

Navan is in the barony of Lower Navan, 29 miles from Dublin, and at the junction of the Blackwater with the Boyne. The principal streets are kept in repair by the county. There are two bridges, one over the Blackwater and the other over the Boyne. There are a court-house, containing rooms for holding the sessions and a suite of assembly-rooms; a bridewell, a county infirmary, and a fever hospital. The parish church is a neat modern building: the Roman Catholic chapel is an extensive building of Grecian architecture. The population of Navan, in 1831, was 4416; that of the whole parish 5292. The town is in the centre of a great corn district, and has an excellent corn-market on Wednesday; there is a market also on Saturday; there are four yearly fairs. There are several corn-mills, a linen yarn-mill, and a woollen manufactory near the town. Some sacking and packing canvas are made. The corporation consists of a portreeve and twelve burgesses, with a town-clerk and other officers. The portreeve acts as a justice of the peace for the borough conjointly with the county magistrates. Navan returned members to the Irish parliament from the time of Elizabeth till the Union. Petty sessions are held here every fortnight, and the quarter-sessions for the division twice in the year. The parish is at the head of a union, both in the Established and Catholic churches. There are several schools; one of them a Catholic seminary for youths designed for the priesthood or either of the learned professions.

Oidecastle is in the barony of Demifore or Half Fowre, 58 miles from Dublin. The town comprehends 237 houses, and a population of 1531; the whole parish has 778 houses, and a population of 4718. There are a church, a plain modern building: a large but plain Catholic chapel; and a Primitive Methodist chapel. There is a large school-house for a Lancasterian school, capable of containing 1000 children. This school has an endowment of 800*l.* a year. Petty sessions are held here every fortnight; and the market, which is on Monday, is one of the largest yarn-markets in the county. There are extensive corn-mills near the town. There are three considerable yearly fairs. There are considerable limestone quarries and large flour-mills in the parish. The living is a rectory not united; the parish is included in a Catholic union.

Slane is in the barony of Upper Slane, 28 miles from Dublin. In the early ages of Christianity it was the seat of a bishopric. The town is pleasantly situated on the north bank of the Boyne, over which there is a bridge. The surrounding country is rich; and the houses are chiefly modern and of neat appearance. Slane Castle, the seat of the marquis Conyngham, is on the bank of the river just above the town. The population of the town, in 1831, was 896; of the whole parish, 2516. The parish is the head of a Catholic union: the living in the Established Church is a rectory, in the gift of the crown. There are several schools. There is a group of tumuli in the neighbourhood; the largest is a mound 70 feet high, and having at the top an irregular area, 300 feet in circumference. This mound, when opened, was found to conceal the entrance to a gallery leading to a remarkable excavation or cavern. Slane is one of the stations of the county constabulary force.

Ashbourne is a small place in the barony of Ratoath, 13 or 14 miles from Dublin on the road to Londonderry. It is a small place containing 60 houses and a population of 473. It has a Catholic chapel, a neat modern building.

Clonard, in the barony of Upper Moyferagh, 33 miles from Dublin, was a place of note in antient times. It had an abbey which became the seat of a bishop, whose diocese

was augmented, previous to A.D. 1152, by the addition of the bishoprics of Trim, Ardracean, Dunshaughlin, and Slane. This diocese was afterwards designated the diocese of Meath, but the cathedral continued to be at Clonard till A.D. 1206. The abbey had previously been repeatedly plundered by the Danes or the natives; and about A.D. 1175 Hugh de Lacy erected an Augustinian monastery, probably on its ruins. Clonard was the scene of conflict in the war of 1641 and the insurrection of 1798. It is a station of the county constabulary police, though a mere village or hamlet of 10 houses and 66 inhabitants. There is a large Catholic chapel in the village, the parish church is half a mile distant.

Clonee is in the parish and barony of Dunboyne, just within the boundary of the county, about 9 miles from Dublin, on the road to Navan. Clonee is a station for the county constabulary force. The population in 1831 was 217.

Crossakeel is about 46 miles from Dublin. It is in the parish of Kilskyre, or Kilskeer, and in the barony of Upper Kells. Petty-sessions are held here once a fortnight and it is a station of the county constabulary force: there are three yearly fairs. The parish church is in the village, and there is a dispensary. The population of the village in 1831 was 290; of the whole parish, 4537.

Dunshaughlin, in the barony of Ratoath, 17 miles from Dublin, was formerly a corporate town. It is now a post town or village of 157 houses and 913 inhabitants for the town, or 261 houses and 1940 inhabitants for the whole parish. It has a parish church of modern erection, and a Catholic chapel. The petty sessions are held every fortnight, and the quarter-sessions for the division, twice in the year: it is a station for the county constabulary force. There is a dispensary in the town, and there are two public schools.

Enfield is in the parish of Rathcore and in the barony of Lower Moyferagh, 26 miles from Dublin, near the Royal Canal. It is a station of the county constabulary. It had in 1831, 45 houses and 302 inhabitants.

Nobber is in the barony of Morgallion, 40 miles from Dublin. It was antiently a fortified town, and was regarded as of importance. It now contains 58 houses and 371 inhabitants; the whole parish has 671 houses and 3952 inhabitants. The church is a plain neat building; the Catholic chapel is also a neat building of modern erection; and there is a school-house. Near Nobber is a large Danish camp, and in the churchyard are the remains of a structure, supposed to have belonged to the Knights of St. John of Jerusalem. There is a well attended cattle and pig fair. Nobber is a constabulary police station. Carolan, the celebrated Irish harper, was born here.

Ratoath is in the barony of Ratoath, 15 miles from Dublin. It was a parliamentary borough previous to the Union, by which it was disfranchised. There were in 1831, 96 houses and 552 inhabitants in the town, or 283 houses and 1779 inhabitants in the whole parish. There are three yearly fairs, but no market; a trifling manufacture of sacking and of linen is carried on. It is one of the stations of the county constabulary force.

Ecclesiastical and Legal Divisions.—The county is for the most part included in the diocese of Meath; but small portions are comprehended in those of Armagh and Kilmore; all these dioceses are in the ecclesiastical province of Armagh. The county is included in the home circuit. The assizes are held at Trim. The Easter and Michaelmas sessions for the two divisions of the county are held at Kells and Dunshaughlin; the Hilary and Midsummer sessions, at Trim and Navan. Before the Union Meath sent 14 members to the Irish parliament, two for the county, and two each for Trim, Kells, Navan, Athboy, Duleek, and Ratoath; at present it sends only the two county members, who are elected at Trim.

The police force of the county on 1st January, 1836, was, 1 magistrate, 7 chief constables, including subinspectors (of whom 5 were of the first and 2 of the second class), 58 constables, and 266 subconstables, with 9 horses. The cost of maintaining the constabulary for 1835 was 11,893*l.* 13*s.* 4*d.*, of which amount 6197*l.* 3*s.* 4*d.* was chargeable against the county.

The county-gaol at Trim has been much improved, as respects the male side of the prison, but much is yet requisite to be done to bring the discipline of the prison to what it should be. It is clean; the prisoners generally are classified, and considerable advance has been made in the system

of instruction in trades. There are two schools in the prison, and a treadmill. The bridewells at Navan and Kells are both tolerably extensive prisons, containing sixteen cells, two day-rooms, and two yards; they have every means of classification required by the Prison Act. (*Appendix to Fourteenth and Fifteenth Reports of Inspectors-General, 1836.*) The number of persons committed for criminal offences in 1836 was—for offences against the person 85 (44 convicted, 41 acquitted or discharged); for offences against property committed with violence 28 (convicted 9, acquitted or discharged 19); for offences against property without violence 107 (convicted 54, acquitted or discharged 53); for malicious offences against property, such as arson, killing or maiming cattle, and the like, 4 (1 convicted, 3 acquitted or discharged); for forgery and offences against the currency 4 (2 convicted, and 2 acquitted or discharged); for other offences 105 (45 convicted, 60 acquitted or discharged): making a total of 333 persons committed, of whom 155 were convicted and 178 acquitted or discharged. There was no person executed. Of the persons committed, 277 were males (1 of them under 16 years) and 56 females (1 under 16): 71 could read and write, 54 could read only, and 110 were entirely ignorant; of 98 the degree of instruction they had received could not be ascertained.

The lunatic asylum for the counties of Meath, Louth, Dublin, and Wicklow, is the Richmond Lunatic Asylum at Dublin. Of 284 patients in that institution on 1st January, 1837, 30 belonged to this county. The county infirmary is at Navan, and there were, in 1833, fever hospitals at Kells and Navan, and nineteen dispensaries at different places in the county, supported in nearly equal proportions by private subscriptions and grand-jury presentments.

History; Antiquities.—Meath appears to have been included by Ptolemy in the territory of the *Blavioi* (Blaini), or *Εβλαβοι* (Eblani), a nation whose sway extended over the neighbouring counties of Dublin and Wicklow, and whose name may be traced in the first syllable of the province of Leinster. At an early period Meath constituted one of the kingdoms into which Ireland was divided, and comprehended, it is likely, not only the present counties of East Meath and West Meath, but also the whole or part of those of Longford, Cavan, and King's County. Teamor, now Tarah Hill, near the Boyne, between Dunshaughlin and Navan, was the residence of the sovereign of Ireland and the seat of the supreme government, and the place where St. Patrick made his first efforts for the conversion of the Irish to Christianity. It is probable that the kingdom of Meath was erected in the second century of the Christian era as the immediate domain of the Irish monarchs; or if not then first erected into a kingdom, was placed under the immediate government of the Irish monarchs, while the rest of the island owed them only feudal obedience. At a subsequent period the government of Meath was separated from the monarchy, which was so far weakened by the separation as to become little more than a nominal supremacy; the kings of Meath ranked as subordinate princes, but they constituted one of the two lines of the great family of the Hy-Nialls, by which the supreme government was alternately possessed. Teamor ceased to be the seat of the national government.

In the invasions of the Northmen, or Danes, the kingdom of Meath suffered severely. Turges, a Danish leader, in the early part of the ninth century, established himself at Lough Rive (Ree?), and after cruelly ravaging the kingdoms of Connaught and Meath, was seized and put to death, probably at Lough Uar, near Mullingar in the present county of West Meath, by Melaghlin, or Malachi, king of Meath, who afterwards acquired the supreme power. The Northmen however soon renewed their attacks, and civil dissensions diverted the Irish from resisting the common foe. For several centuries Meath was exposed to their ravages, or those of other Irish princes with whom the kings of Meath were at war.

Traces of this period of confusion exist in the numerous camps and earthworks that overspread the district; and the frequent destruction of monasteries and towns recorded in the annals of the religious houses is another attestation of the prevalent ruin. The last king of Ireland of the Hy-Niall family was Melaghlin II., who, though reduced to abdicate the supreme authority for a time in favour of Brian Boromy, king of Munster, resumed it upon the death of that prince (who fell in battle against the Northmen at Clontarf near Dublin, A.D. 1014), and reigned till his own

death, A.D. 1022, about 150 years before the invasion of Ireland by Henry II.

Before the invasion of the English, Dermot, or Dermot MacMurchad, king of Leinster, had reduced O'Melaghlin, or Melaghlin, king of Meath, and other princes, into a state of subjection; but having roused indignation by the abduction of the daughter of Melaghlin, who had married O'Ruarc, or O'Rourke, king of Breifne, or Brehny (now the county of Leitrim), he was expelled by Melaghlin and others, aided by his own subjects, and compelled to flee to England, where he engaged the Anglo-Normans in the conquest of his native island. Richard, earl of Strigul or Chepstow, commonly called Strongbow, the leader of these auxiliaries, took possession of Meath (A.D. 1171), which was conferred by Henry II. as a county palatine (or feudal lordship, the holder of which had several regal rights), on Hugh de Lacy, who was appointed governor of the English pale or district. Hugh de Lacy built a strong fortress at Trim, which was burned, A.D. 1173, in an attempt which the Irish made, under their king Roderick, to reconquer the country. The Irish were however repelled, and the ruined castle of Trim was restored. De Lacy parcelled out his territories among his followers, whom he created barons, whence is derived the subdivision of counties into baronies.

Meath however appears to have passed again into the power of the natives; for in 1178 De Lacy, who had been reappointed governor of Ireland, and held that office for a short time, restored the English power there. (*Gordon's Hist. of Ireland.*) In the general rebellion excited by the petulance of Prince (afterwards King) John, whom his father Henry II. sent over as governor, Meath was preserved to the English by the valour of William Petit, who defeated the Irish invaders (A.D. 1186). About the same time Hugh de Lacy was assassinated by one of the workmen employed on a castle he was then erecting at Durrogh, in what is now King's County. His son, Hugh de Lacy the Second, who appears to have succeeded him in his county of Meath, was afterwards appointed governor of Ireland, in which office however he was soon superseded, agreeable to the policy, at least the practice, of that day, which seldom allowed a governor to retain office any length of time. De Lacy, in his character of earl of Meath, was engaged as auxiliary (A.D. 1200) in a contest between two Irish princes for the sovereignty of Connaught; and having been reappointed by King John lord-justice or governor of Ireland, he was defeated by John De Courcy, the Anglo-Norman earl of Ulster, whom he was commissioned to arrest and send over to England. He succeeded however in getting De Courcy into his hands by treachery and sending him over to England. He afterwards received the earldom of Ulster as his reward.

The ambition and power of Hugh de Lacy, now earl of Ulster, and of his brother Walter, who appears to have succeeded him in the earldom of Meath, having excited the jealousy of John, that king visited Ireland in person (A.D. 1210), and spent some months in reducing the fortresses in Meath and Ulster belonging to those nobles, who had fled to France, and did not obtain restoration to their estates and honours without the payment of a heavy fine. Meath seems at this time to have lost its privilege as a palatine county, and to have been made subject to the jurisdiction of the king's officers. The De Lacys acted a conspicuous part in the feuds of the Anglo-Norman lords of the Pale, and Meath suffered from these intestine commotions. Upon the decease of Earl Walter, Meath came to his two daughters, who divided his inheritance between them. West Meath, which fell to the elder, who was married to Sir Theobald Verdon, appears to have been so neglected, and fell into such a state of anarchy, that it did not obey the English laws for above a hundred years. (*Baron Finglas's Breviat.*, temp. Henry VIII.) East Meath, the portion of the younger daughter, married to Sir Geoffry Genneville, was also wrested from its owners, either by native chieftains or Anglo-Norman rivals.

The English dominion, never fully established, appears rather to have decayed during the reigns of the later Plantagenet and the Lancastrian princes, and the civil war of the Roses. The native Irish renewed their incursions; and in A.D. 1329, the English under Lord Thomas Butler sustained a severe defeat from them near Mullingar in West Meath. Richard, duke of York, lord-deputy in the reign of Henry VI., erected castles along the border of Meath and other counties in order to repress them. The Irish chieftains

appear to have levied a tribute upon the English settlers, in consideration of leaving them in quiet, similar to the black mail levied by the Scotch Highland chieftains upon the neighbouring Lowland lairds and tenantry. The county of Meath paid at one time a yearly pension to the O'Connors of 60%.

In the reign of Henry VIII., when the power of the English began to revive, Meath was invaded by an Irish chieftain, Con Bucah O'Neill, or O'Neal (A.D. 1520); but he quickly withdrew on the approach of the earl of Surrey, lord-deputy. In a rising in favour of the Papacy, which took place at the Reformation, the Irish broke into Meath, destroyed Navan, and, after mustering their forces at Tarah Hill, set out to return home, but were overtaken and entirely routed (A.D. 1539). In A.D. 1540 the natives assembled in West Meath, with a view to break into the English pale; but dispersed on learning that preparations had been made to resist them. Just at the close of the reign of Henry VIII., the ancient county of Meath was divided; and West Meath, including the present counties of West Meath and Longford, and part of King's County, was erected into a separate county. Cavan, which was partly formed out of Meath, was erected into a separate county by Sir John Perrot, lord-deputy in the reign of Elizabeth. In the great rebellion of 1641, Meath was again the scene of hostilities. Trim was entered by the English troops, who designed to make it a military post; and an attempt of the Irish to surprise the garrison was defeated by a bold and successful sally (A.D. 1642). Sir Charles Coote, one of the best officers of the English, and commander of the garrison, fell in the action. In 1643 negotiations for peace between the English and the insurgents were carried on at Trim. In 1647 Trim was besieged by the insurgents under their general Preston, who, having learned that Col. Jones, the parliamentary governor of Dublin, was on his march to relieve the place, set out in order to surprise the capital, but was met on the road and entirely defeated. Trim served as a place of retreat to some of the Royalists on their defeat at Rathmenes near Dublin, in 1649: but after the storming of Drogheda, and the massacre of the garrison by Cromwell in the same year, Trim was surrendered by the Royalists without resistance.

In the war of the English revolution the battle of the Boyne was fought (A.D. 1690) close upon the border of this county, between Drogheda and Slane. The two armies subsequently crossed the county from north to south, that of James in retreat, that of William in pursuit. In the rebellion of 1798 some outrages were committed at Dunboyne by a party of insurgents, who were very shortly defeated at Ratoath; but the victors having separated, the vanquished party rallied and cut off part of them at Cloncee Bridge. Some further outrages were committed at Dunshaughlin, and immediately a considerable part of the population of the county rose in rebellion: a body of men, 4000 according to some accounts, took post on Tara Hill, where they were defeated with considerable slaughter by the troops and yeomanry. Part of the fugitives took refuge in the bogs, from which they continued for three weeks to make excursions for plunder and devastation.

There are several remains of antiquity in the county. At Tarah, or Taragh, once the seat of the Irish monarchs, are considerable earthworks. Two splendid torques, or collars of pure gold, were dug up here in 1813. There are considerable ruins of the castles of Scurlogstown, Dunmoe, Athlumley, and Asigh. Slane Castle and one or two others have been fitted up as residences. There are round-towers at Kells and at Donoughmore near Navan. There are numerous ruins of ancient monastic edifices: those of the monastery at Duleek, supposed to be the most ancient monastic edifice built of stone and mortar in Ireland, present some remarkable traces of rude architecture. The front of the ancient cathedral at Clonard yet exists, and there are several stone crosses. The ruins of Bective Abbey are extensive and picturesque.

(Wakefield's *Ireland*; *Parliamentary Papers*; Harris's *Hibernica*; Gordon's and Cox's *History of Ireland*.)

MEATH, WEST, or as it is sometimes written in one word, WESTMEATH, is an inland county of the province of Leinster in Ireland, bounded on the north by the county of Cavan in Ulster, from which it is separated by Lough Sheelin or Shillin; on the north-east, east, and south-east by the county of Meath; on the south by King's County; on the west by the county of Roscommon in Connaught,

from which it is separated by Lough Ree and the river Shannon; and on the north-west by the county of Longford. The greatest length is, from east-north-east to west-south-west, from the county of Meath near Clonmellon, to the bank of the Shannon opposite Athlone, 45 miles; the greatest breadth, at right angles to the length, is from the neighbourhood of Kinnegad to that of Rathowen, both on the mail-road from Dublin to Sligo, 25 miles. The area is estimated in the Population Returns for 1831 at 370,053 English statute acres, or 578 square miles. The population in 1831 was 136,872, giving nearly 237 inhabitants to a square mile. In area it can scarcely be compared with any English county; it is larger than Monmouthshire, and less than Hertfordshire; in amount of population it is rather below Hertfordshire, but in density rather exceeds it.

Surface, Geological Character, and Hydrography.—The county is for the most part a gently undulating surface, not rising in any part to a very great height. Knock Eynce, or Ion, on the border of Lough Deveragh, is about 850 feet high; Benfore, or Ben of Fowre, near the village of Fowre, not far from Lough Lano or Leno, is 760 feet high. These, with the other principal elevations, are in the northern part of the county. The whole belongs to the central carboniferous limestone district of Ireland. There are two small districts, one just round Moate-a-Grenogue, and the other in the same neighbourhood, but rather more to the south-west, which are occupied by the yellow sandstone, a formation consisting of quartzite sandstone conglomerate, of varying grain, which passes into sandstone. These beds are considered to belong to the same period as the carboniferous limestone, of which series of formations they constitute the lowest members.

The western side of the county belongs immediately to the basin of the Shannon, which forms its western boundary, separating it from the county of Roscommon. Lough Ree, the largest of the series of lakes into which that river expands, is also on the western border. This noble sheet of water is 15 miles long from north to south, and of a varying breadth, above 7 miles in one part. Its outline is exceedingly broken and irregular, and its surface studded with a number of small islands finely wooded. Those adjacent to Westmeath are, Innismore, or Inchemore, containing 104 acres, once the site of a monastery; Hare Island, 57 acres, with the ruins of an abbey; Innisturk, or Inchturk, 24 acres; and Innisboffin, or Incheboffin, 27 acres, formerly the site of an abbey; besides a number of smaller islands. An inlet at the southern extremity of Lough Ree, connected with it by a straight so narrow as properly to constitute it another lake, is almost entirely enclosed within the county. This subordinate lake, which is about two miles long from east to west, and in one part above a mile and a half wide, contains a large island called Friar's Island, well wooded at its western extremity. The streams which flow into the Shannon or into Lough Ree are all small. Two of the principal rise about 3 miles west of Moate-a-Grenogue; one of them flows in a circuitous channel north-west into the inlet of Lough Ree; the other flows due west into the Shannon near Long Island, below Athlone. Another stream, which rises three miles north of Moate, and several other streams in the north-west, flow into the Inny, which joins Lough Ree on the border of the county of Longford. There are several small lakes on this side of the county; some of these communicate by small streams with Lough Ree; others have no visible outlet. Bogs also are numerous, though none of them are of any great extent.

The central part of the county is drained by streams that empty their waters into several inland lakes, which are connected by small streams with each other, and ultimately with the river Shannon. The northernmost of these is Lough Sheelin, or Shillin, on the north border of the county, from which lough a small stream communicates with Lough Keinal, also on the border. From Lough Keinal the connecting stream flows southward, first along the border, separating West Meath from Longford, and then through the county into Lough Deveragh. This fine sheet of water extends 5 or 6 miles in length from north-west to south-east, and has a breadth varying from 2½ or 3 miles near the north-west end, to little more than a quarter of a mile near the south-east extremity. The banks are hilly, and some of the loftiest elevations in the county are in the surrounding district. There are plantations or other woodlands on some parts of the shore. The district north of the Lough, extending as far as Lough Keinal and Lough Shillin, is almost entirely bog, especially the tract through which the

connecting stream flows. Lough Deveragh receives some small streams; and others, including the Glorc, which is the outlet of a small lake (Lough Glorc), north-east of Lough Deveragh, fall into the connecting stream.

From the north-western extremity of Lough Deveragh another stream flows south-west into Lough Iron, a shallow lake of about 3 miles long from north-west to south-east, and about half a mile broad. Several streams flow into the connecting stream between Lough Deveragh and Lough Iron or into the latter lake, and carry off the superfluous water of small lakes or bogs. Lough Glyn on the north-west border toward Longford, and Lough Gar, are thus connected with this central system.

A small brook forms the communication between Lough Iron and Lough Owheh, or Hoyle, $3\frac{1}{2}$ miles long from north-west to south-east, and about $1\frac{1}{2}$ miles broad. The banks rise gently from the lake, and are fertile and well wooded. On a small islet in the lake is a rude chapel with a burial-ground, once much resorted to by pilgrims. A supply of water is drawn from Lough Hoyle for the Royal Canal. From Lough Hoyle a small stream flows in a winding channel southward past Mullingar into Lough Ennel, $4\frac{1}{2}$ or 5 miles long from north-east to south-west, and above 2 miles broad at the widest part. This lake, sometimes called Belvidere, is studded with small islands. A number of streams flow into this lough.

These lakes communicate with the Shannon by two different streams. The Inny flows from the north-western extremity of Lough Iron to the border of the county, which it skirts, and then into the county of Longford, to which it may be considered as chiefly belonging. It flows into Lough Ree. The Brosna flows from the south-west extremity of Lough Ennel by Kilbeggan into King's County, to which it chiefly belongs. It receives a number of small streams, drains the southern parts of the county, and falls into the Shannon in the neighbourhood of Banagher.

All that part of the county which we have described is included in the basin of the Shannon, though for convenience the central lake-district has been described separately. The eastern side of the county belongs to the basin of the Boyne. A number of small streams rise on that side of the county and flow eastward into that river: the most important is the Deel, one branch of which rises near Mullingar, and another is the outlet of a small system of lakes near the north-east border of the county. The lakes of this system are Lough Bawn, the White Lake, and some very small ones on the borders; and Lough Lene, Lein, or Lane, and Lough-a-Deel within the border: Lough Lene, the largest of the group, is about $2\frac{1}{2}$ miles long from west-north-west to east-south-east, and nearly a mile broad. Its waters are peculiarly clear, and it contains several islets.

The eastern and south-eastern sides of the county abound with bogs, and some of them are of very considerable extent. The lakes of West Meath abound in pike and trout: the latter are very fine, and form an important article of food.

This county is among the most picturesque in Ireland. It is considered to be excelled only by Kerry, Fermanagh, Wicklow, and Waterford.

Agriculture.—The landed estates in the county are not very large, but there are a number of gentlemen of moderate fortune. In the eastern parts the soil is a heavy loam from 7 to 12 inches deep; the northern parts, which are hilly and adapted for sheep-walks, are chiefly devoted to grazing black cattle. In the western parts the soil is generally light; there is a great deal of bog. The farms do not commonly exceed 100 acres or thereabouts, and in many cases are as small as 15, 10, 7, or even 3 acres. The resident gentry usually farm a considerable portion of their own estates. The average rent of arable land is from 1*l.* 5*s.* to 1*l.* 10*s.*; land of good quality will sometimes let for 2*l.*, that of inferior quality sometimes for not more than 1*l.* The system of 'con acres,' or lands let to the cottiers for the purpose of growing a single crop of potatoes, is prevalent in almost all parts of the county. (*Appendix to the Report of Commissioners for Inquiring into the State of the Irish Poor.*) The chief crops raised by the farmer are oats and potatoes; a very little wheat, some barley, flax, rape, and clover are grown. Fences, except in the neighbourhood of demesnes, are generally neglected; in some parts they consist simply of earthen banks without anything growing upon them. Dairy farming is practised to some extent in this county, but not to such an extent as the nature of the soil would warrant. A considerable quantity of good butter

is made, which is sent by Dublin to England. The long-horned cattle are much valued; some of the best specimens are grazed in this county, and all the stock participate in the blood. Sheep are not a favourite stock, but there are some excellent ones of the long-woolled breed. Pigs, as usual, are generally kept. The breed of horses is superior; many are brought from Connaught and reared for sale in Dublin. Wood is not plentiful; there are some small copses and underwoods, the remains of ancient forests; and some thriving young plantations. The following table shows the sales of grain in the years 1826 and 1835:—

Market.	Barrels of Wheat of 20 Stone.		Barrels of Oats of 14 Stone.		Barrels of Barley of 19 Stone.	
	1826.	1835.	1826.	1835.	1826.	1835.
Mullingar . . .	None	None	{ 7900; average of these and the in- termediate years. }		{ 4500; average of these and the in- termediate years. }	
Clonmellon . . .	{ markets not esta- blished }	200	{ markets not esta- blished }	5,000	{ markets not esta- blished }	None.
Castletown Delvin . . .		300		900		None.
Ballinacargy . . .	None	300	28,000	25,000	2,500	2,500
Coolnahea . . .	None	None	2,000	1,900	350	250
Rathowen . . .	400	50	4,000	2,000	150	None.
Moate . . .	Average from 1826 to 1830		4,800			
..	Average from 1831 to 1836		4,900			

No return was received from the markets of Castle Pollard and Kilbeggan. No wheat appears to have been sold at Moate either in the years 1826 and 1835 or in the interval between them. Collinstown is not noticed. The name Coolnahea in the tables is, we suspect, an error. We know not with what place to identify it.

The manufactures of the county are not important; they consist chiefly of the most necessary articles. The returns of 1831 give 285 adult males as engaged in manufacture, 92 in that of linen (chiefly coarse), 22 in that of cotton, 20 in that of friezes and other woollens, chiefly coarse, and 2 in the silk manufacture. The remainder were not specified. To these must be added 820 weavers, returned among the retail tradesmen and handicraftsmen; but what fabric they produced is not stated.

Communications.—The Shannon is navigable for steam-boats conveying goods and passengers, or acting as steam-tugs to other vessels, throughout that part which borders on this county. The Royal Canal, which connects Dublin and the east coast with the upper part of the Shannon at Tarmonbarry, crosses this county from east to north-west, passing near Killucan and Mullingar. A branch from the Grand Canal between Philipstown and Tullamore in King's County, to Kilbeggan, is partly in this county.

The principal roads are those from Dublin to Longford and Athlone respectively. The Longford road enters this county from that of Meath near Kinnegad, and runs north-west by Mullingar and Rathowen into the county of Longford. A branch from this at Mullingar takes a rather more westerly direction from Ballinacargy to Ballymahon. The Athlone road branches from that to Longford just after it enters the county at Kinnegad; and runs westward by Rochford Bridge, Tyrrell's Pass, Kilbeggan and Moate, to Athlone. The road from Dublin to Granard runs through the northern part of the county by Castle Pollard. The principal traffic is carried on by the canals and by the Athlone road; but the number of passengers is rather the greatest by the Longford and Athlone roads. Many however travel by the Royal Canal to Mullingar, and by the branch of the Grand Canal to Kilbeggan.

Divisions, Towns, &c.—West Meath is divided into 12 baronies, whose relative situation and amount of population are as follows:—

			Population in 1831.
Brawney. . .	W. . .		7,396
Clonlonan. . .	S.W. . .		12,538
Corkarce. . .	Central. . .		6,630
Delvin. . .	E. . .		9,984
Demifore, or Half Fowre. . .	N. . .		15,559
Farbill. . .	E. . .		8,746
Fartullagh. . .	S.E. . .		8,903
Kilkenny West. . .	W. . .		11,159
Moyashel and Magheradernan, or Magheradernon. . .	Central. . .		12,732
Moycashel. . .	S. . .		16,167
Moygoish. . .	N.W. . .		11,702
Rathcourath. . .	N.W. . .		15,064
			136,872

Population.

Date.	How ascertained.	Inhabited Houses.	Families.	Families chiefly employed in Agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	Families not included in the preceding classes.	Males.	Females.	Total.
1792	Estimated by Dr. Beaufort .	13,693	69,000
1813	Under Act of 1812 .	no return	no return
1821	Under Act 55 Geo. III., c. 120	23,478	128,042
1831	Under Act 1 Will. IV., c. 19	23,803	25,331	16,824	3,694	4,813	67,700	69,172	136,872

The county town is Mullingar; the parliamentary borough and market-town of Athlone is partly in this county, partly in that of Rosecommon; and there are the market and post towns of Kilbeggan, Moate, Rathowen, Castletown-Delvin, Ballinacargy, Clonmellon, and Castle Pollard (of these Kilbeggan is a corporate town); the market-town of Collins-town; and the post towns of Kinnegad, Ballymore, Tyrrell's Pass, Killucan, Rochfort Bridge, and Drumree. Athlone is described elsewhere. [ATHLONE.]

Mullingar is in the barony of Moyashel and Magheraderinan, but the parish extends into that of Fartullagh; it is nearly 50 miles from Dublin by Maynooth, Clonard, and Kinnegad. It was one of the towns founded by the English settlers of Meath. In the war of the Revolution the town was fortified by General Ginkel, and became the rendezvous of William's army, preparatory to the siege of Athlone. The town is surrounded on three sides by the Royal Canal, and consists of a principal street, about half a mile long, and some smaller ones. The number of houses in 1831 was 727 for the town, or 1538 for the whole parish. Those in the town are chiefly of stone. The church is a tolerably spacious building, erected in the present century, with a handsome tower and spire. There are a handsome Catholic chapel and one or two Dissenting meeting-houses. The county court-house is convenient; there are a county gaol, erected within the last few years, and an older prison, now used only for females; a county infirmary, an hospital, barracks for a thousand men, and a neat and commodious market-house in the centre of the town. The population of the town of Mullingar in 1831 was 4295, that of the whole parish 8845. The assizes for the county, the quarter-sessions for the division, and petty-sessions for the district, are held, and a portion of the county constabulary have their station here. The Royal Canal gives the town the benefit of water-carriage; and considerable business is done at the market (which is held on Thursday) in corn, butter, and frieze coating. There are four yearly fairs for cattle; one of them is a considerable horse-fair. The town is not incorporated; but a charter of King Charles II. granted to the lord of the manor several privileges, and to the freeholders the privilege of sending two members to parliament; this last was abolished at the Union. The living is a vicarage in the diocese of Meath, and in the patronage of the crown. The parish is at the head of a Catholic union.

Kilbeggan is in the barony of Moycashel, 56 miles from Dublin, on the road to Athlone. It was the scene of a conflict in the rebellion of 1798 between a party of insurgents and the regiment of Northumberland militia. The town contains 350 houses; the whole parish 732: half of those in the town are well built, and have slate roofs. The church was originally part of an antient monastic institution, dissolved at the Reformation. There are a handsome Catholic chapel and a Methodist meeting-house. The market-house is a neat building. The population in 1831 was 1985 for the town, or 4039 for the whole parish. The trade of the town is considerable: distilling, brewing, milling, and snuff-making are carried on; much butter is sold at the market, which is held on Saturday, and there are four yearly fairs. A branch from the Grand Canal recently made bids fair to increase the prosperity of the town. Kilbeggan was incorporated by James I.; the corporation consists of a portreeve, twelve burgesses, and an unlimited number of freemen. The portreeve has jurisdiction in the borough conjointly with the county magistrates. There is a borough court for the recovery of debts; petty sessions for the district are held here. The town formerly sent two members to the Irish parliament, but was disfranchised at the Union. The living is a perpetual curacy; the parish is, in the Catholic arrangements, united with an adjoining one.

Moate-a-Grenogue is in the barony of Clonlunan, 66 miles from Dublin, on the road to Athlone. In the war of the English Revolution a party of the Jacobites were defeated here by William's army under General De Ginkel, and compelled to flee to Athlone. The town consists almost entirely of one street, and comprehended, in 1831, 304 houses, the greater part slated, the rest thatched. The population of the town in 1831 was 1785. The trade of the place appears to be diminishing; the manufacture of cottons and linens has much declined, and several breweries and distilleries have been discontinued. There is a market on Thursday, one of the most important for oats in the county; and there are several yearly fairs. The quarter-sessions for one division of the county are held here, and also petty sessions for the district. There is a convenient court-house and a small bridewell attached to it. A party of the county constabulary have their station here. The town is in the two parishes of Killeigh and Kilmanaghan, chiefly in the former, the parish church of which is in the town. There are a Catholic chapel and several dissenting places of worship; also a dispensary.

Rathowen is in the barony of Moygoish, 64 miles from Dublin, on the Longford road, and 13 or 14 miles from Mullingar. The town contained, in 1831, a parish church, a Catholic chapel of the union in which the parish is concluded, a market-house, and 107 houses, almost all thatched. The population was 605 for the town, or 2170 for the whole parish of Rathaspeet, in which it is situated. There is a market on Tuesday, chiefly for oats, and two fairs in the year. It is one of the stations of the county constabulary.

Castletown Delvin is in the barony of Delvin, 50 miles from Dublin. An old castle, built here by De Lacy, lord of Meath, was for a time the residence of the Nugents, who built also the castle of Clonin or Clonyn in the parish. Of the castle built by De Lacy the ruins remain: the walls form a quadrangle with towers at the corners. There are several other castellated ruins in the neighbourhood. Clonin was burnt during the civil war of Charles I. on the approach of Cromwell. The name of Clonyn is retained by the present residence of the marquis of Westmeath. The town consisted in 1831 of a single street of 77 houses, with a population of 419. There are a parish church, a plain old building, but in good repair, and a Catholic chapel. The market lately established is on Friday, and there are three fairs in the year. Petty-sessions are held, and a body of the county constabulary have their station here. The living is a vicarage in the diocese of Meath. The parish is at the head of a Catholic parochial union. There is a dispensary.

Ballinacargy, or Balnacarrig, is in the barony of Moygoish, 58 miles from Dublin. The town had, in 1831, 46 houses, neatly built and roofed with slate. It is in the parish of Kilbixy, and the Roman Catholic chapel for the parish is in the town. There are a market on Wednesday, the largest in the county for oats and barley, and a market on Saturday for provisions; also two yearly fairs. Petty-sessions are held here, and the town is one of the stations of the county constabulary. There are a dispensary and a free school.

Clonmellon is in the barony of Delvin, close upon the border of the county. It is a neat little town, comprehending, in 1831, 179 houses, and a population of 960. There are a considerable corn-market on Tuesday, lately established, and two yearly fairs. Petty-sessions are held, and a portion of the county constabulary are posted here. The parish church of Killua, in which parish the town is situated, is near the town; it is a neat building, with a spire.

Castle Pollard is in the barony of Demifore, 54 miles

from Dublin, about 2 miles north-east of Lough Deveragh, and about the same distance west of Lough Lane. It consists of five streets meeting in an open space or square, in which stands the market-house. It contained, in 1831, 291 houses, and a population of 1618. The parish church of Rathgarrue, or Rathgarth, or Rathgraff (in which parish the town stands), a modern building, is not far from the town. The tower and part of the old church, with the churchyard, in which is the school-house, are also near the town. There are a Catholic chapel, a dispensary, a fever hospital, a savings' bank, and a parochial school. There are a market on Wednesday and four yearly fairs. Petty-sessions are held, and a party of the county constabulary have their station in the town. Kinturk, the seat of the Pollard family, Pakenham-hall, the seat of the earl of Longford, and other demesnes, are near the town. The old castle of Kinturk, which gave name to the town, is entirely demolished.

Collinstown is a little place on the road from Dublin to Granard. It is at the junction of four roads forming a cross, and has only twenty or thirty houses, chiefly thatched, with a market-house in the centre of the town, and a Roman Catholic chapel near it. It is in a pleasant district of diversified scenery, near the southern extremity of Lough Lane. There are a market on Saturday and two yearly fairs. There are petty-sessions held, and a body of the county constabulary posted in the town. The town is in the parish of St. Feighan of Fowre.

Kinnegad is in the barony of Farbill, about 11 miles from Mullingar, and 37 from Dublin. It is in a great thoroughfare, just at the separation of the roads from Dublin to Longford and Athlone, and consists of one principal street. It has 123 houses, with a population of 670. The church is a neat Gothic building of modern date; there are a Catholic chapel, a school-house, and a market-house. No market is held, though there is a charter for one, and there is only one yearly fair. The living is a perpetual curacy detached from the parish of Killucan.

Ballymore is in the barony of Rathconrath, 15 miles from Mullingar, and 73 from Dublin. There formerly existed here a monastery for Premonstratensian canons and Benedictine nuns, who occupied different portions of the same building. The church of this monastery was for a short time the cathedral church of the diocese of Meath. In the civil war of 1641 Ballymore was a principal military station of the English; and in the war of the Revolution the Irish were posted here, until beaten from the town by General De Ginkel. A garrison of a thousand men in Fort Ballymore, in an island of the neighbouring Lough Shodie or Scudie, surrendered themselves prisoners of war shortly after. The town, which is partly in Killure parish, but chiefly in that of Ballymore, consisted, in 1831, of 121 houses, chiefly small houses or cabins, forming one long street. There are a parish church and a Catholic chapel. There was formerly a market, but it is now discontinued. There are two yearly fairs. Petty-sessions are held, and the county constabulary have a station in the town. Not far from the town is a round tower, the only remains of a castle, said to have belonged to the De Lacys.

Tyrrell's Pass is in the barony of Fartullagh, about 51 miles from Dublin, on the road to Athlone. The town takes its name from having been for many years the seat of the Tyrrell family. There are some remains, near the town, of their castle. The town consists of about 80 houses, chiefly well built, with slated roofs, forming one principal street. There is an area in the centre of the town, formerly used as a market-place, but the market is now discontinued. The parish church of Clonfadd (in which parish the town is partly situated) and a Methodist meeting-house are in the town. There are a savings' bank, a charitable loan fund, and a dispensary. There are two cattle fairs, which are well attended.

Killucan is in the barony of Farbill, 42 miles from Dublin. It takes its name from an abbey founded by St. Lucian, the church of which subsequently became parochial. The De Lacy family had a castle here, of which the foundations and some of the outworks are still discernible. Four yearly fairs are held in the town; petty sessions are also held, and there is a station of the county constabulary. The town had, in 1831, 29 houses and 206 inhabitants; the whole parish 1491 houses. The parish church is a modern structure. There are in the parish two Catholic chapels, four public schools, and a 'flax society,' which gives employment to about 100 poor women.

Rochfort Bridge, or, as it is sometimes called, Beggar's Bridge, is in Fartullagh barony, and about 47 miles from Dublin, on the road to Athlone. It contained, in 1831, only 27 houses and 171 inhabitants. The parish church of Castlecoast, in which the place stands, and a national school, are in the town. The county constabulary have a station here.

Drumree is in Delvin hundred. It contains the parish church of Kileumney (in which parish the town is), a parish school-house, and a dispensary. It had, in 1831, 37 houses and 197 inhabitants.

The village of Fore or Fowre, or, more accurately, of St. Feighan of Fowre, is in the barony of Demifore, not far from Lough Lane. Though now only a small village, it was anciently of importance. A monastery for regular canons was founded here in the seventh century, and is said to have contained, a few years after its foundation, 3000 monks. This monastery, after having been repeatedly destroyed by fire, was re-founded in the beginning of the thirteenth century by Walter de Lacy, for Benedictine monks. There are still some remains of the abbey, and there is an ancient and massive building, supposed to have been a hermitage. In the fifteenth century considerable pains were taken to fortify the town, which had acquired the privileges of a corporate borough. There are the ruins of several square towers, two of the gates, and traces of the town wall, the extent of which shows its former size. Fowre was a borough by prescription, and returned two members to the Irish parliament, until it was disfranchised by the Union. The village had, in 1831, 19 houses and 119 inhabitants.

Ecclesiastical and Legal Divisions.—The county is almost entirely in the diocese of Meath; a small portion on the north-west side is in the diocese of Ardagh, which was till lately held by the archbishop of Tuam, but is now to be permanently united to the diocese of Kilmore. Both Kilmore and Meath are in the ecclesiastical province of Armagh.

West Meath is included in the home circuit: the assizes are held at Mullingar, where are the county court-house and gaol. Quarter-sessions for the county are held at Mullingar and Moate-a-Grenogue, where are a court-house and a bridewell.

West Meath returned ten members to the Irish parliament, two for the county, and two each for Mullingar, Athlone, Kilboggan, and Fowre. At present it returns three to the Imperial parliament, viz. two for the county, who are elected at Mullingar, and one for the borough of Athlone.

The police force of the county, on the 1st of January, 1836, consisted of 1 magistrate, 7 chief constables, including sub-inspectors (viz. 4 of the first and 3 of the second class), 50 constables, and 222 subconstables, with 9 horses. The expense of maintaining the constabulary for 1835 amounted to 10,051*l.* 4*s.* 9*d.*, of which 5480*l.* 16*s.* was chargeable against the county.

The county gaol at Mullingar has lately experienced a very extensive change for the better. A commencement has been made of the system of instruction in trades. But the discipline of the female side still requires very much attention: the accommodation is very insufficient, and there is no classification. There are two schools in the prison, and a tread-mill for those sentenced to hard labour. The Moate bridewell is on a tolerably large scale, with every accommodation requisite for classifying the prisoners, and is clean and well kept. (*Appendix to Fourteenth and Fifteenth Reports of Inspectors-General, 1836.*)

The number of committals for criminal offences in 1836 was, for offences against the person, 282 (of whom 181 were convicted, 98 acquitted or discharged); for offences against property committed with violence, 43 (20 convicted, 23 acquitted or discharged); for offences against property committed without violence, 164 (112 convicted, 52 acquitted or discharged); for malicious offences against property, arson, &c., 22 (8 convicted, 14 acquitted or discharged); for forgery and offences against the currency, 7 (2 convicted, 5 acquitted or discharged); for other offences, 243 (226 convicted, 17 acquitted or discharged): making a total of 761 persons committed, of whom 552 were convicted and 209 acquitted or discharged. Only one person was executed. Of the persons committed, 633 were males (5 of them under sixteen years) and 128 females (2 under sixteen); 342 could read and write, 118 could read only, and 296 were

entirely ignorant. Of 5 the degree of instruction they had received could not be ascertained.

The Lunatic Asylum for the counties of West Meath, King's, Queen's, and Longford, is at Maryborough, in Queen's County: of 131 patients in this institution on the 1st of January, 1837, 28 belonged to this county. The county infirmary is at Mullingar. There were, in the year 1833, a fever hospital at Castle Pollard, and fourteen dispensaries in different parts of the county, supported in equal proportions by grand jury presentments and private contributions.

History and Antiquities.—This county was included in the kingdom of Meath, of which it formed the western division. In common with the rest of that kingdom it suffered severely both from the ravages of the Danes and from civil dissensions, and was included in the county palatine of Meath, granted by Henry II. of England to Hugh de Lacy, one of the Anglo-Norman barons who assisted in the reduction of the county. [MEATH.] It was the scene of frequent hostilities for several centuries between the native Irish, who were not entirely expelled or subdued, and the English, and was, for above a century before its formation into a separate county, in a state of anarchy, in which the English laws ceased to be observed. West Meath was separated from Meath or East Meath in the 34th of Henry VIII.; at its first separation it included Longford, which was not detached from it and formed into a separate county until the reign of Elizabeth. King's County, which was partly taken from West Meath, had been formed A.D. 1557, in the 5th of Philip and Mary.

The great insurrection of 1641 is said to have been planned and agreed upon at the abbey of Mullisfarnham in this county, which being much resorted to for religious purposes, and therefore less liable to suspicion, was chosen by the conspirators as their place of meeting.

In 1648 Athlone, in which the partisans of Renuncini, the papal nuncio and head of the extreme Catholic party, had endeavoured to maintain themselves, was taken by the confederate royalists under Lord Clanrickarde and General Preston.

In the war of the English revolution West Meath was the scene of some important operations. [ATHLONE.] An extensive change of the landed property of the county resulted from the confiscations which followed these wars. The older families have disappeared almost entirely from the grand-jury list.

In the Rebellion of 1798 the county was but little disturbed, though many of the peasantry had furnished themselves with pikes. In September of that year, during the invasion of Ireland by the French detachment under General Humbert, the insurgents assembled and joined those of the neighbouring counties in an attempt to seize Granard, in which they were repulsed. They were put down by a subsequent defeat at Brumbrusna, near Multifarnham.

There are many vestiges of antiquity scattered through the county. There are numerous ruins of ancient castles, including some erected by the De Lacys. Sonnagh Castle, one of these, stands on the verge of a small but picturesque lake. Of monastic buildings there are several ruins; and some churches, formerly conventual, are still used for divine worship by Catholics or Protestants.

(*Wakefield's Ireland; Parliamentary Papers; Harris's Hibernica; Gordon's and Cox's History of Ireland.*)

MEATH, DIOCESE OF. Several small bishoprics (of which the principal were Duleek, Clonard, Kells, Trim, Ardracean, Dunshaughlin, Slane, and Fowre) gradually coalesced into one see, which, at the end of the twelfth century, received the name of Meath, and was further augmented, A.D. 1568, by the addition of the bishopric of Clonmacnois. The diocese comprehends nearly the whole of the counties of Meath; West Meath; a considerable part of King's County; small portions of Cavan, Longford, and Kildare; and part of the county of the town of Drogheda. It extends in length from east to west from the sea to the Shannon, 80 English miles; and has a medium breadth from north to south of 25 English miles. There is no cathedral; neither are there a dean and chapter. The only dignities are the deanery of Clonmacnois and the arch-deaconry of Meath. The want of a chapter is supplied by a synod, of which every incumbent is a member, and the arch-deacon president. The diocese is included in the province of Armagh: it is not affected by the Act 3 and 4 William IV., c. 37. The bishop has precedence of all the other

Irish bishops. His residence is at Ardracean near Navan.

The number of parishes is given by Dr. Beaufort (1792) at two hundred and twenty-four, and part of another; the number of benefices at ninety-nine; and of churches at seventy-seven. In 1834 the number of parishes was two hundred and twenty; of benefices, one hundred and five; of which forty-seven were unions of two or more parishes; of churches, one hundred; of other episcopal places of worship six; of Presbyterian meeting-houses, three; of other Protestant dissenting places of worship, eighteen; and of Catholic chapels, one hundred and fifty-six: giving a total of two hundred and eighty-three places of worship of all denominations. The population of the diocese in 1834 was 404,059; of whom 377,562 were Catholics, 25,626 members of the Establishment, 672 Presbyterians, and 199 other Protestant dissenters.

There were at the same time 578 daily schools, in which were 28,885 children under instruction, being in the proportion of 9.05 per cent. to the whole population of the diocese: in the relative number of children under instruction as compared with the population, Meath ranks twelfth among the thirty-two dioceses of Ireland. Of the above-mentioned schools, 45 were in connection with the National Board. (*First and Second Reports of the Commissioners of Public Instruction in Ireland.*)

The lands belonging to the see comprise 29,269 statute acres, of which 20,266 are of profitable land. The average yearly revenue of the bishopric, for the three years preceding 1832, was 5220*l.* 10*s.* 6*d.*

There is a Roman Catholic bishopric of Meath. The bishop is a suffragan of the Roman Catholic archbishop of Armagh. There were in this diocese, in 1834, 66 parish priests, including the bishop, who officiates at Mullingar, where is the cathedral, a handsome and spacious Gothic edifice of modern erection; and 60 coadjutors or curates.

MEAUX, a town in France, capital of an arrondissement in the department of Seine et Marne. It is on the bank of the Aube, 23 miles in a direct line east by north of Paris, or 27 miles by the road.

The original name was Latinized as Iatinum; and it was the capital of the Meldi, a Celtic people who were included in the Roman province of Lugdunensis Quarta or Senonia. Toward the overthrow of the Roman empire, Iatinum assumed the name of Meldi, whence the modern Meaux. In the early history of the Franks it was a place of considerable consequence. It was included in the possessions of the counts of Champagne, and was united to the domains of the crown by the marriage of Philippe IV. le Bel, A.D. 1281, with the countess of Champagne. It was one of the places in which the reformed faith early met with a favourable reception; but it afterwards came into the hands of the League, from which it revolted to join Henri IV. It was the chief town of Brie Champenoise.

The town is divided by the Marne into two unequal parts, and the canal of the Oureq passes by the foot of its ancient walls, which have been planted with trees and converted into promenades. The streets are not well laid out, but the houses are tolerably good. The principal building is the cathedral, commenced in the eleventh century. The architecture is Gothic; the magnificent choir contains a marble statue of Bossuet, who was bishop of this see. There are two parish churches and a Protestant church. The Palais de Justice, or court-house, was built by the ancient counts of Champagne. There are good barracks for cavalry. The population in 1831 was 8481 for the town, or 8537 for the whole commune; in 1836, 7809 for the commune. The inhabitants manufacture cottons, leather, glue, saltpetre, vinegar, and earthenware; and carry on a considerable trade in corn, especially oats, sent to Paris, flour, cheese (called from the district Brie cheese, and accounted very excellent), wool, cattle, poultry, wood, and coal. The old bridge across the Marne, from the great fall of the water which the bridge causes, impedes the navigation, which is carried on here by a very ancient navigable cut, called the Cornillon Canal. There is a well-attended weekly market, and there are four yearly fairs. There are a subordinate court of justice, and a court for commercial suits; several government offices, two hospitals, two seminaries for the priesthood, a high school, a Protestant Bible Society, a public library of 11,000 volumes, another library at the bishop's palace, a museum, and a society of agriculture, science, and arts.

Meaux is the seat of a bishopric, established in the fourth century, and now having for its diocese the department of Seine et Marne. The bishop is a suffragan of the archbishop of Paris.

The arrondissement of Meaux has an area of 463 square miles: the population in 1831 was 93,417; in 1836 it was 90,965. It is subdivided into seven cantons or districts, each under a justice of the peace, and comprehends 161 communes. Millstones and marble are quarried in it; and there is a considerable stratum of gypsum in the neighbourhood of Meaux.

MECCA. [ARABIA.]

MECHAIN, PIERRE-FRANÇOIS-ANDRÉ, was born 16th August, 1744, at Laon, a town of France, in the present department of Aisne. After quitting the school 'des ponts et chaussées,' where the limited means of his parent had enabled him to pursue his studies only for a short time, he engaged himself as mathematical tutor, and devoted his leisure to the cultivation of astronomy. Shortly after this an accident brought him under the notice and patronage of Lalande. The necessity of affording some pecuniary assistance to his father obliged Mechain to dispose of an astronomical instrument which, by rigid economy, he had recently been able to purchase. Lalande became the purchaser, and, after acquainting himself with the past history of Mechain, procured for him a government appointment as hydrographer, in which he was engaged in the construction of marine charts, and, jointly with M. Bretonnière, in the survey of the French coast between Nieuport and St. Malo. His attention however appears to have been chiefly directed to the theory of eclipses, and of comets, of which he discovered eleven, and computed the orbits of twenty-four. To his memoir on the comet of 1532, which it was expected would re-appear in 1789 or 1790, the prize of the Academy of Sciences was awarded, and the same year (1782) he was admitted a member of that society. In 1791 the National Convention having determined upon employing the length of the arc of the meridian comprised between Dunkirk and Barcelona as the basis of their new measures, the measurement of the southern portion of this arc, between Rodez and Barcelona, was, at the recommendation of the Academy, confided to Mechain. The northern portion was allotted to M. Delambre, to whose account of the entire survey (*Système Métrique*, Paris, 1806-7-10, 3 vols. 4to.), containing many interesting particulars relative to Mechain, we refer the reader. It will be sufficient here to state that Mechain experienced his share of the difficulties and annoyances which have usually attended such operations, and that the breaking out of the French revolution, which prevented his return from Spain, and the consequent anxiety for his family whom he had left behind, brought upon him a melancholy state of mind from which he never wholly recovered. His skill as an observer is particularly mentioned by Delambre, and also the accuracy of all his calculations connected with the survey. Of this Mechain himself was unconscious. He had employed the repeating circle, an instrument which he regarded as absolutely infallible, and finding a difference of three seconds between his observations at Barcelona and Montjoux, he attributed it wholly to his own incapacity. Upon his return to Paris, which he reached with much personal risk, fearing to divulge this discrepancy, he refused to deliver his papers to the Academy. The subject continuing to prey upon his mind, he applied, after several years, to the French board of longitude, and urged them to prolong the measurement of the arc from Barcelona to the Balearic Islands. To this the Board consented, but being unwilling to dispense with his services at the Paris Observatory, they suggested that Mechain should not be the conductor of the survey. This however would have been to relinquish the chief object of his application. He obtained permission to depart, but soon after his arrival in Spain he was attacked by an epidemic disorder, of which he died on the 20th of September, 1805, at Castellon, a town of Catalonia.

Before his departure he entrusted all the manuscripts referring to his previous expedition to M. Delambre. They have since been arranged and deposited in the Paris Observatory, together with so much of his correspondence as related in any way to the survey.

His published works are few. They consist of papers printed in the 'Connaissance des Temps,' subsequently to 1785, in which year he succeeded Jeaurat as editor of that ephemeris, and several memoirs in the Transactions of the

French Institute, commencing with the year 1782. These memoirs refer chiefly to the cometary theory and eclipses.

(Delambre's Notice of the Life of Mechain, in the *Biog. Univers.*; Hutton's *Mathematical Dictionary*, &c.)

MECHANICS is the science in which are investigated the actions of bodies on one another, either directly or by means of machinery.

These actions may be simple pressures without motion; as when one body being supported in any manner, another is placed upon it, either vertically or in some oblique position: or they may be such as are accompanied by motion, and these may arise either from the mutual attractions which all bodies in nature exercise upon each other, or from the collisions of bodies in motion with others which may be previously in motion or at rest.

The term is particularly applied to the mutual actions of solid bodies: the actions of fluids on solids form, in part, the subjects of hydrostatics and hydrodynamics; but these, as well as pneumatics, are now frequently included under the general name mechanics. When bodies are at rest and the actions are such as to maintain them in that state, the laws of the actions constitute that branch which is called statics; but when motion is concerned, the laws and phenomena constitute what is called dynamics.

In all the branches of general mechanics the investigations are founded on experiment and are conducted by geometrical or algebraical processes; hence the science forms one of the departments of experimental philosophy, and also of mixed mathematics: this last denomination is applied to mechanics because in the latter are involved several qualities of bodies which do not enter into the researches of pure science, such as mass or quantity of material, inertia, hardness, elasticity, time, space, and power or force. The last-mentioned term is used to express the cause of the actions of bodies on one another: but we have no other conception of it than that it is productive of motion or of a tendency to motion; or that it arrests an actual motion or renders a tendency to motion ineffectual. When opposing forces act on a body so as to destroy each other's effects and keep the body unmoved, that body is said to be in a state of equilibrium; and this state is distinguished from that of mere rest, since the latter implies the absence of any cause by which the body might change its place.

The invention of simple machines for moving masses of any material which it might be beyond the unaided power of man to transport to a distance, must have taken place in the earliest ages of the world. Human ingenuity would readily suggest the application of a rod or bar of wood or iron, for the purpose of lifting a heavy body from the ground; and very little experience would suffice to show that rolling or pushing a block of stone up sloping ground was a much easier operation than that of raising it vertically by the strength of men's arms. Thus may have arisen the employment of the lever and inclined plane; and from these, subsequently, the wheel and axle, the pulley, the wedge, and the screw were derived. The simple means here indicated would be sufficient, with the aid of manual labour, to build up the most massive cyclopean edifice; and even the vast materials which form the roofs of the Egyptian temples may have been raised to their places by means of inclined planes, formed of earth for the purpose, on the exterior of the walls, and afterwards removed.

The steps by which the art of constructing machines advanced have not been distinctly recorded; and the work of Vitruvius on architecture is almost the only source from whence can be obtained an account of such as were in use in and before the time of that engineer (the age of Augustus or Vespasian). From the descriptions there given it appears that among the mechanical powers then in use were the lever, the windlass, and the assemblage of pulleys. Vitruvius also mentions some ingenious contrivances for transporting heavy blocks of stone from the quarries, and a forcing-pump, the invention of which he ascribes to Ctesibius, for supplying the public fountains. He describes a complex machinery, consisting of wheels driving each other by cogs or teeth, which was applied to carriages or ships for the purpose of measuring the distances travelled or sailed; and he enters fully into the construction of engines for throwing darts or masses of stone. The muscular strength of men was then employed as a moving power in turning mills: wheels impelled by river currents acting on float-boards (pennæ) gave motion to machinery for grinding corn; and wheels turned by men walking on them were

used for raising water by buckets or otherwise. Vitruvius generally mentions the names given by the Greeks to the machinery; and it might, without great risk of error, be presumed that much of that which he describes was in use among the latter people at, or even before, the time when the Parthenon was raised. There are no distinct intimations of the existence of windmills till the twelfth century. The expansive force of steam can only be said to have become a moving power at the end of the seventeenth century, and then it was employed merely to raise water. Its general application to machinery must be dated from the year 1768.

In tracing the progress of discovery concerning the mathematical theory of mechanical action, we shall have little to notice till we come to the sixteenth century; for the ancients, who devoted themselves with so much ardour to the researches of pure science, almost entirely neglected the application of the latter to subjects which appeared to them to terminate in mere practical utility. It must be observed however that Aristotle, who left no department of nature untouched, has noticed, in his mechanical questions, the equilibrium of unequal weights on the unequal arms of a balanced lever, though he gives a very unphilosophical reason for the fact. But in his 'Physics' he states correctly that if two forces move with velocities reciprocally proportional to their intensities, they will exert equal efforts: this may apply to a well-known property of the lever, but it may have been meant to refer only to the effect of two unequal bodies moving with unequal velocities, and striking each other or a third body.

Sicily enjoys the honour of having given birth to the first philosopher who can properly be said to have been a theoretical mechanician: we allude to Archimedes, who died about 212 B.C., and in whose works there is direct evidence of an effort to determine the principle of equilibrium in machines. Commencing, in the treatise whose Latin title is 'De Æquiponderantibus,' with the axiom that two equal weights balance each other on a lever (of uniform dimensions), when at equal distances from the fulcrum, he supposes the weights to be divided into an equal number of equal parts, and that the parts are removed to equal distances from the point of support; observing then that the equilibrium still subsists, he proceeds, by the method of exhaustions, to show that it always will take place provided the bodies are inversely proportional to their distances from the fulcrum. Archimedes thence concludes that there must exist in every one body, considered as an assemblage of smaller bodies, a centre of force (that is, a centre of gravity) corresponding to the fulcrum in the former case; and he proceeds, by the analysis of that day, to investigate the seat of the centre of force in a triangle, a parabola, and a paraboloid.

This philosopher has obtained eternal celebrity by the contrivances which he is said to have adopted for the defence of Syracuse. No precise account is given of the machinery which he employed to raise up and destroy the galleys of the enemy, and the effects are probably exaggerated. The vessels must have been close to the walls, and it is conceivable that, by hooks at the ends of chains which were suspended from levers on the ramparts, the rigging, or some parts of the turrets erected as usual on the decks, in order to enable the assailants to pass over the parapets, might be caught; then, the levers being raised by the force of men or otherwise, the vessels or the turrets would be easily overturned.

During about 1800 years, which elapsed between the time of Archimedes and that of Cardan, we have no other notices concerning the theory of mechanics (beyond those which occur in the writings of the former mathematician), than such as are contained in the 'Mathematical Collections' of Pappus, which amount merely to a statement that the ancients had reduced the theory of every machine to that of the lever, and an unsuccessful attempt to explain the cause of the equilibrium of a body on an inclined plane. It is remarkable moreover that both Cardan and, subsequently, the marquis Ubaldi (the latter of whom published, in 1577, a treatise in which he explains at length the combinations of pulleys, and reduces their theory to that of the lever) should also have given erroneous solutions of the problem concerning that equilibrium. The discovery of the true theory of the inclined plane was however, about the same time, made by Stevinus, a native of Flanders. This mathematician and engineer supposed a chain of uniform

dimensions to be placed on a doubly inclined plane, having a common summit and base, the chain being perfectly free to slide on the planes, and its ends hanging vertically to equal distances below the base; then, in order to prove that the chain would remain at rest, he shows that if any motion should take place, it might continue for ever; and this he concludes to be absurd. As the argument holds good when one of the two planes is in a vertical position, Stevinus infers that, when a body is in equilibrio upon a plane, the retaining power is to the weight as the height of the plane is to its length; and he further shows that if three forces act on any point, they hold the latter in equilibrio when they are proportional to the three sides of a triangle formed by lines drawn parallel to the directions of the forces. It should be remarked however that Stevinus demonstrates the law in that case only in which two of the forces are at right angles to each other. He died in 1635.

To Galileo we are indebted for the first reduction of mechanical propositions to purely mathematical formulæ. In order to demonstrate the equilibrium of a body on an inclined plane, he imagined the weight and the sustaining power to be applied to the ends of a bent lever whose arms were of equal length and perpendicular to the vertical and slant sides of the plane; then reducing the lever to a straight one, between the lines of direction of the weight and power, it was easy to prove that the forces in equilibrio on the plane were also in equilibrio on the lever, and were to one another as the length to the height of the plane.

But the most important discoveries of Galileo were those which relate to the times of descent, the spaces descended, and the velocities acquired when bodies fall by the action of gravity. He made observations on the motions of pendulums, and determined that the times of their vibrations are proportioned to the square roots of their lengths; he also gave theorems for the composition of two motions, when both are uniform, when both are accelerated, and when one is uniform and the other accelerated. Nor should we omit to state that he was the first to obtain expressions for the strength of materials in resisting the strains to which they are subject. It deserves notice moreover that Galileo, in opposing the arguments of one of his contemporaries concerning the law of the descent of bodies by gravity, makes a supposition that the spaces descended with the accelerated motion may be divided into equal parts, each so small that the motion during the time of describing it may, without sensible error, be considered as uniform; an hypothesis corresponding exactly to that which, agreeably to the principles of the modern analysis, is now employed in investigations concerning variable motions.

The theory of the motions of fluids was, apparently, first cultivated in Italy by Castelli, who wrote on the subject in 1638; and about the same time Torricelli, having discovered the existence of a space void of air in the upper part of a tube filled with mercury, its open end being immersed in a vessel of that fluid, was enabled to refute the ancient notion that nature *abhorred* a vacuum. The latter was subsequently led to the conclusion that the pressure of the atmosphere is the cause of the support of a column of mercury in a tube, and also of the ascent of water in pumps. Both of these writers were pupils of Galileo; and, soon after the time of this philosopher, the French mathematicians Descartes, Pascal, Fermat, and Roberval, prosecuted with ardour the new science, as that of mechanics was called. Among the fruits of their researches may be named the determination of the centres of oscillation and percussion in a body or system of bodies vibrating about a fixed axis. The impulse given by Galileo, being thus continued by a succession of men of talent both in Italy and France, caused the science to advance with an accelerated movement, and soon put it in a condition to embrace all the subjects of terrestrial physics.

The mechanics of that age was not however entirely emancipated from the trammels of a false philosophy; and the theory of Descartes, concerning the communication of motion when bodies strike each other, is remarkable on account of the metaphysical principle which it involves. In speaking of the collision of bodies, he gives as a reason why the same momentum should exist after as before the impact, that it depends on the divine immutability. God having created a certain quantity of motion to serve as the cause of all the operations of nature, that quantity, he conceives, can never be increased or diminished. Yet there is some reason to think that Descartes had better notions con-

cerning the phenomena of collision, for he states correctly, in one of his letters, that the motion of a body when it strikes another which is at rest becomes divided between the two masses, and that the resulting velocity is diminished as the mass is augmented. The chief feature in the physics of Descartes is his supposition that the planets revolve about the sun in vortices of æther, the particles of which, having acquired a certain degree of centrifugal force, act on the planets and prevent them from falling together in the centre of the system. He supposed that the like vortices surround each planet; but the particles of æther, having less specific gravity than the bodies on the surface of the planet, the tendency of these bodies to that surface prevails over the force by which the æther causes them to recede from thence.

The laws of the collision of bodies, which had been in vain attempted by Descartes, were at length, and nearly at the same time, discovered by the English mathematicians Wallis and Sir Christopher Wren, and by Huyghens on the Continent. The first of these, in his treatise 'De Motu' (1670), divides bodies into such as are hard and such as are elastic, and he explains the phenomena attending the shock of bodies of both kinds. In that of hard bodies he adopts as an hypothesis that the body struck destroys as much motion in the striking body as the latter communicates to it; and in elastic bodies he considers the forces of compression and restitution to be proportional, in each, to the velocity before the shock. The name of Huyghens is become celebrated from the discovery of the properties of cycloidal curves, and the attempt to make the lower extremity of a clock-pendulum vibrate in an arc of that kind, in order that the times of vibration might be equal, whatever were the extent of the arc described. This attempt did not succeed; but, being led in the course of his inquiries to investigate the position of the centre of oscillation in a compound pendulum, Huyghens found that when several pendulous bodies descend by gravity and afterwards re-ascend by the acquired velocities, in whatever way they may act upon each other, their common centre of gravity cannot rise higher than the point from whence it descended. This proposition is considered as proved from the fact that, if it were otherwise, the centre of gravity might by mechanical means be made to rise continually higher, and thus perpetual motion might ensue: but this is impossible.

In 1687 Newton's great work concerning the mathematical principles of natural philosophy was first published, and from that time the mechanical sciences, which had hitherto been confined to the action of bodies on each other at the surface of the earth, were made to comprehend the laws of planetary motion. The 'Principia,' as the work is called, commences with the three well known axioms in philosophy, or laws of motion. Assuming then as an hypothesis, that all the bodies of the universe and all the particles of every body exert on each other mutual attractions; assuming also that the planetary bodies were originally put in motion by impulsive forces; the rotations of these bodies on their axes, their revolutions in their orbits, and all the perturbations by which their movements are varied, are explained by means of the elementary theorem for the composition and resolution of motions. The oscillations of pendulums, the theory of projectiles, the movements of fluids, and the resistance opposed by the latter to the motions of bodies immersed in them, are also in the same work investigated at length.

Contemporary with Wallis, Wren, and Newton in England, were, on the Continent, the celebrated Leibnitz and the two elder Bernoullis, all of whom contributed greatly to the advancement of mechanical science by their investigations concerning the laws of motion in terrestrial bodies; and to the rivalry as well as the talents of these great men we owe some of the most important discoveries in that branch of learning. At this time the fluxional or differential calculus was discovered, and had acquired an algorithm; and they who adopted its principles appear to have been anxious to show its superiority over the ancient geometrical analysis, by proposing to their opponents problems which could scarcely be solved by the latter method. With some such views Leibnitz proposed the determination of that curve along which a body descending would describe equal vertical spaces in equal times; James Bernoulli proposed to find the figure assumed by a flexible cord or chain when suspended at the extremities [CATENARY]; and John Bernoulli, to find the curve of swiftest descent. [CYCLOID.]

P. C., No. 918.

Numerous other problems of the like nature were given out among the parties, and the solutions could not fail, if no other benefit arose, of carrying the new calculus to a considerable degree of perfection.

From the time of Newton mechanical science was, till lately, but little cultivated in this country; but on the Continent a succession of illustrious men continued to prosecute the investigation of subjects connected with it, and by the employment of analytical processes they rendered comparatively easy the application of its principles to the researches of physical astronomy.

The mathematicians who may be considered as the immediate successors of Newton were chiefly Euler, D'Alembert, and Clairaut; and in the works of the first of these are investigated all the circumstances attending the phenomena of rectilinear and curvilinear motion when a body in vacuo or in a resisting medium is subject to any forces whatever. But the most remarkable event in the history of the sciences, after the discoveries of the English philosopher, was the solution of the celebrated problem of the three bodies; or that whose object is to determine the motions of a body when attracted by and revolving about another, and continually disturbed by the attraction of a third. This was, at the same time (about 1732), and independently of each other, accomplished by the three learned men above named, and it now constitutes the basis of the whole planetary theory. The 'Mécanique Analytique' of La Grange, which was published in 1788, and the 'Mécanique Céleste' of La Place (1798 to 1825), contain the last accessions which the mechanical sciences have since received; and these sciences now comprehend the laws of force or motion, from the properties of the simple lever to the phenomena of the heavenly bodies.

It may have been seen above that the first general principle in mechanics is that of the equilibrium of bodies on a lever; and a knowledge of it may be ascribed to Archimedes. The extension of the principle to all the mechanical powers was long an unsolved problem, and the solution may be said to have been first made known to the world by the discovery of Stevinus relating to the sustaining power on an inclined plane. A second general principle may be conceived to be that of the composition of motions or forces; and its discovery is to be ascribed to Galileo. Daniel Bernoulli (about 1726) was the first to demonstrate the rule of the composition of forces independently of motion; but the application of the principle as a means of obtaining general equations of equilibrium seems to have been first made in the 'Projet d'une Nouvelle Mécanique,' which was published by Varignon in 1687.

La Grange treats as a third principle in mechanics that of *virtual velocities*. By this is meant those which bodies in equilibrio would have at the first instant of their motion, in the event of the equilibrium being disturbed. Indications of this principle are found in the writings of Galileo, Wallis, and Descartes, but John Bernoulli is thought to have been the first who showed its utility in resolving statical problems. [VIRTUAL VELOCITIES.] A general method of solving mechanical propositions was discovered by D'Alembert, and it may be thus enunciated. If there be impressed on bodies motions which they are forced to change in consequence of their mutual actions, those motions may be considered as compounded of the motions which the bodies do really take, and of those which are destroyed. Whence it results that these last must be such that if they alone existed the bodies would be in equilibrio. In order to avoid the decompositions of motions which this principle requires, an equation is frequently made between the general analytical expression for a force and the expression for those forces which produce the observed motions. [FORCES, IMPRESSED.] The manner of estimating the value of a mechanical force is various; and a difference in the expression of the value gave rise to disputes which continued during nearly all the first half of the eighteenth century. [FORCE.]

Besides the principles above mentioned there occur in mechanical investigations several others, which it will be proper to state briefly in this place.

That which is called the *preservation of living forces* is a consequence of the discovery of Huyghens concerning the movement of the centre of gravity in a compound body. For the space described by that centre is expressed by the quotient arising from the sum of the products of the mass of each body into the distance it passes over, divided by the

VOL. XV.—H

sum of the masses; and since the spaces descended by bodies when acted on by gravity are proportional to the squares of the velocities, it follows that the sum of the products of the mass of each body into the square of its velocity is constant, whether the bodies move jointly in any manner, or whether they descend freely through equal vertical spaces.

The preservation of the centre of gravity is a principle which contains the discovery of Newton, that the motion of the common centre of gravity of several bodies is not affected by the mutual attractions of the bodies. It was subsequently extended by D'Alembert, who shows that if the bodies are solicited by a constant accelerative force in directions either parallel to each other or tending to a fixed point, the centre of gravity must describe the same line as if the bodies were free.

The preservation of areas seems to have been discovered simultaneously by Euler, Daniel Bernoulli, and the Chevalier D'Arcy, about 1750. According to the latter it is an extension of Newton's theorem that the radii vectores of revolving bodies describe equal areas in equal times, and it consists in this: that the sum of the products of the masses of revolving bodies into the areas described by their radii vectores about a fixed point is proportional to the time. Or the sum of the products of the masses into the velocities and into the perpendiculars let fall from the fixed point on the lines of direction of the motions is constant.

The principle of least action originally signified, that when bodies act on each other, the sum of the products of the masses into the velocities and spaces described is a minimum. But considered in the most general sense, agreeably to the extension given to it by La Grange, the principle consists in this: that in trajectories described by bodies subject to central forces, the integral of the velocity multiplied by the element of the orbit is always a maximum or a minimum.

A general outline of that part of mechanics which relates to the equilibrium of solid bodies is given under the word **STATICS**; and the details of the subjects may be seen under **LEVER**, **WHEELS**, &c. The part of mechanics which relates to bodies in motion appears under the words referred to in the article **DYNAMICS**.

MECHELEN, called Malines by the French, is a large well-built town in the province of Antwerp, in $51^{\circ} 2'$ N. lat. and $4^{\circ} 29'$ E. long. It stands in a fertile plain on the river Dyle, by which it is intersected. The streets are wide, well paved, and kept remarkably clean. The large square, called La Place d'Armes, and the market-place, are in particular deserving of mention. The cathedral, dedicated to St. Rombaud, the patron saint of Mechelen, is the most remarkable building in the town. Its tower is 348 feet high, and contains a fine peal of bells: it was built in 1451. The other principal buildings are the arsenal, which contains a cannon-foundry; the town-house, the archiepiscopal palace, and the church of the Jesuits. Mechelen contains a college, an academy of painting, a society of fine arts, and a large building which serves as an asylum for 600 widows and aged women.

It appears that as early as the fifth century Mechelen was the capital of a lordship, which was afterwards given in 754 by Pepin to one of his relatives. It was subsequently destroyed by the Normans, and rebuilt in the year 890. In 910 it was ceded by France to the bishop of Liège. At this time it occupied only the left bank of the Dyle, but was extended on the other side of the river in 970. Mechelen was sacked by the Spaniards in 1572, and by the army of the Prince of Orange in 1578. It was taken in 1706 by the Duke of Marlborough; and by the French in 1746, but was restored at the peace of Aix-la-Chapelle. In 1792 it was again taken by the French, who in 1804 destroyed its fortifications.

This town is the seat of an archbishopric, created in 1559 by pope Paul IV. The archbishop is the head of the Catholic church in Belgium, and has for his suffragans the bishops of Namur, Tournay, Aix-la-Chapelle, Trèves, Ghent, Bruges, Liège, and Mayence.

Mechelen carries on an important trade by means of vessels of considerable burthen, which ascend the Schelde and the Dyle at high-water, the influence of the tide being felt a few miles above this town. The principal articles of commerce are corn, oil, hemp, flax, and hops. The lace manufactured at Mechelen has long been in high repute, and bears a great price. There are manufactories of hats,

shawls, coarse woollens, and paper, cotton-mills, dye-houses, breweries, distilleries, and tanneries. It has recently acquired additional importance from the circumstance of its being the central point at which the several railroads of Belgium meet. It is about midway between Brussels and Antwerp, and distant from both about thirteen miles. The population of Mechelen in 1836 was 22,895. (Van der Maclin's *Dictionnaire Géographique de la Province d'Anvers*.)

MECHLIN. [MECHELEN.]

MECHLOIC ACID. This acid was formed in 1835 by Couerbe, by passing chlorine gas over fused meconin. When purified by solution in potash, and precipitation from it by nitric acid, it exists in the state of colourless prismatic crystals, soluble in cold water, but more so in hot: alcohol and ether dissolve it sparingly. It melts at about 257° ; at 376° it is volatilized; and by a strong heat it is decomposed. It is stated by its discoverer to be composed of

Chlorine	.	.	5.43
Organic matter	.	.	94.57
			100.

The organic matter consists of

Hydrogen	.	.	4.070
Carbon	.	.	49.404
Oxygen	.	.	46.526
			100.

MECKLENBURG, which consists of the two grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, is situated in Northern Germany, between $53^{\circ} 8'$ and $54^{\circ} 2'$ N. lat., and $10^{\circ} 40'$ and $13^{\circ} 45'$ E. long., and is bounded on the north by the Baltic, on the east by the Prussian provinces of Pomerania and Brandenburg, on the south by Brandenburg and the Hanoverian principality of Lüneburg, on the west by Lauenburg and the territory of Lübeck. The area (according to Hempel) is 5880 square miles, namely, Mecklenburg-Schwerin 4788, and Mecklenburg-Strelitz 1092. The greatest extent of Mecklenburg, from north to south, or from the peninsula of Fischland to the great Wentower Lake, is 94 miles, and the greatest breadth, from east to west, 127 miles.

Divisions.—*Mecklenburg-Schwerin* is divided into circles or districts. I. *Mecklenburg* (251,476 inhabitants): chief towns, Schwerin, the capital (13,035 inhabitants); Parchim (5690 inhabitants); Ludwigslust, the residence of the grand-duke (nearly 5000 inhabitants). II. *Wenden* (140,482 inhabitants): chief town Güstrow (8620 inhabitants), one of the handsomest towns, and the fourth in size in the grand-duchy. It was for many centuries the residence of the princes, and has several remarkable public edifices, especially the cathedral, which contains some costly monuments of the princes; the palace, which Hempel says is unquestionably the finest princely residence of the middle ages in Mecklenburg, was converted in 1817 into a house of correction. III. *The Principality of Schwerin*: chief town Bützow (3600 inhabitants). IV. *The District of Rostock*: chief town Rostock (29,000 inhabitants). V. *The Lordship of Wismar* (11,420 inhabitants): chief town Wismar (10,000 inhabitants). [SCHWERIN; ROSTOCK; WISMAR.]

Mecklenburg-Strelitz is divided into, I. *The Lordship or Circle of Stargard* (69,762 inhabitants): chief towns, New Strelitz (5767 inhabitants); New Brandenburg (6000 inhabitants); Friedland (4500 inhabitants); Old Strelitz (3090 inhabitants). II. *The Principality of Ratzeburg*, lying quite detached from the grand-duchy, on the frontier of Lauenburg and the lake of Ratzeburg, near Lübeck (14,080 inhabitants). [STRELITZ; RATZEBURG.]

The surface of the country, being a part of the low land of Northern Germany, may be described generally as a plain. There is a ridge or chain of hills which, commencing in the Silesian mountains, traverses the country, and extends in a north-west direction into Holstein. On both sides of this ridge there is some heath, moor, and sand, but a great portion of the land is fertile, and in parts covered with considerable forests. The soil is partly loamy and heavy, partly of a middling quality, and partly sand. The first, which is about one-third of the whole, is very fertile; the second is of very different degrees of quality; the last is everywhere poor, and frequently covered with heath. In Mecklenburg-Schwerin there are sixty-two lakes at least $1\frac{1}{2}$ miles long,

besides many smaller ones. Lake Müritz, which is the largest, is 18 miles long and 8 broad. In Mecklenburg-Strelitz the county of Stargard alone contains fifty-three lakes at least $1\frac{1}{2}$ miles long: the largest is the Tollen Lake, $7\frac{1}{2}$ miles long. Some of the rivers fall into the Baltic, and others into the Elbe. Of the former the principal are the Trave, Stepenitz, Reeknitz, Peene, and Warnow; the last is one of the chief rivers; the length of its course is about 100 miles. At Rostock it suddenly expands to a breadth of 2400 feet, and falls into the sea at Warnemünde. The Elbe only washes the frontier at two places, near Dönitz and Boitzenburg, which lie on its banks. The rivers that fall into the Elbe are, the Elde, which has a course of above 100 miles, and the Havel. The coast of the Baltic, which is but little indented, is generally steep, and high above the sea; and where it is lower, the country is protected from the incursions of the sea by sand-hills. Though Mecklenburg, on the whole, is not a picturesque country, there are some spots of very pleasing appearance about many of the lakes, especially Lake Malchin, and near the sea-coast. The climate is healthy and temperate; but the weather is variable, and the winter often very cold.

Natural Productions.—Agriculture is the chief employment of the inhabitants. Wheat (most of which is exported), rye, barley, oats, peas, and vetches are very abundant. The forests produce oak, beech, and fir timber of excellent quality. There is a good breed of horses, horned cattle, and sheep, which are highly esteemed in other countries. Swine too are abundant. In some parts there is much game, such as wild boars, stags and deer, bustards, partridges, snipes, wild geese, and ducks. The geese of Mecklenburg are celebrated for their size and good quality. Fish abound both in the sea and all the lakes. The country is poor in minerals, and no mines of any kind are worked.

Trade and Manufactures.—The manufactures are inconsiderable, but they are improving, and great pains are taken to promote the woollen manufacture. Favourably situated as the country is between the Baltic and the Elbe, its commerce is far more important than its manufactures, yet by no means so extensive and profitable as might be expected; for the laws allow the importation and exportation of almost all articles, and the duties are low. The vicinity of Hamburg and Lübeck, and the heavy duties imposed by the Prussian tariff, are great checks on the trade of Mecklenburg. The *Revenue* of Mecklenburg-Schwerin is considerable, amounting to 2,617,000 rix-dollars per annum, of which nearly $1\frac{1}{2}$ millions are produced by the domains. The revenue of Mecklenburg-Strelitz is stated at 400,000 rix-dollars, but is probably higher, for the domains alone yield 300,000 rix-dollars.

Religion and Education.—The great majority of the inhabitants are Lutherans. There are in Mecklenburg-Schwerin 4000 Jews and 590 Roman Catholics, and in Mecklenburg-Strelitz 800 Jews and 50 Roman Catholics. The Calvinists are only 250 in both states. The sovereigns are the heads of the church. There appears to be a very inadequate religious instruction, since, according to Hempel (the most recent and the best authority), there are in Mecklenburg-Schwerin 461 Protestant churches with only 322 officiating clergy, and in Mecklenburg-Strelitz 150 churches with 68 clergymen. Education was formerly very much neglected. The schools for the people were few and ill conducted. The learned institutions were better, and the university of Rostock has had many eminent professors. Considerable improvements were made by duke Frederick, who in 1782 founded a seminary for schoolmasters; but a thorough reform was left for his successor Frederick Francis, who during his long reign devoted his unceasing attention to this object. The improvement in Mecklenburg-Strelitz has been equally great. The university of Rostock has only about 120 students.

The military force of Mecklenburg-Schwerin is 3298 men, and that of Mecklenburg-Strelitz 742 men. Their contingents to the army of the Confederation exceed their ordinary establishment, that of Mecklenburg-Schwerin being 3580, and a reserve of 1740 men, and that of Mecklenburg-Strelitz 718 men and a reserve of 359 men. Both form part of the second division of the 10th corps of the army of the Confederation. Their respective contributions to the treasury are 1333 $\frac{1}{2}$ florins and 666 $\frac{1}{2}$ florins. In the full council Schwerin has two votes and Strelitz one; in the select council they have together one vote, viz. the 14th.

Form of Government.—The co-operation of estates in the affairs of the country may be traced to the remotest periods. The constitution, in its present form, is founded on compacts entered into between the princes and the estates in 1523, 1572, 1621, and especially on that of 1755. The grand-dukes have the whole executive power; but share with the estates the legislative power and the right of imposing taxes. The grand-dukes indeed govern their respective dominions independently of each other, but the estates of the two grand-duchies are inseparably united by a compact made in 1523, called the Landes-Union. The clergy, formerly the first estate, having been excluded after the Reformation, the assembly has since consisted of two estates: the first is called the equestrian order, which includes all the owners of noble estates (whether they are noblemen or not). They have great privileges and immunities, and are rich and powerful. There are now 572 landowners who have seats and votes in the assembly. The second estate consists of the deputies of the forty-four towns. They meet annually at Sternberg and Malchin alternately. In general above 200 members attend. The grand-duke alone has the right of introducing such measures as he deems necessary, which is done by what are called 'propositions.' The estates have the right to accept or reject them, and they may likewise represent what they consider as grievances, and petition for their being remedied.

The history of the country is rather intricate, in consequence of the frequent changes in the reigning family by the formation of new branches and the extinction of others, which occasioned continual partitions of the territory. Mecklenburg was inhabited by the Heruli and the Vandals. On their emigrating to the south they were succeeded by Slavonian (Wendish) tribes, of whom the most powerful were the Obotriti, to whose prince Heinrich Burewin, son of Pridislaus (who had embraced the Christian religion), Henry the Lion gave his daughter Matilda. Pridislaus was declared in 1170 a prince of the empire, and was the ancestor of the succeeding sovereigns of Mecklenburg. These princes received the ducal title from the emperor Charles IV. in 1340, and assumed that of grand duke on joining the German Confederation in 1815.

(Hassel: Siem; Hirschelmann; and chiefly Hempel, *Geog. Statist. Hist. Handbuch des Mecklenburger Landes*, Güstrow, 1837.)

MECONIC ACID, a substance which is found only in opium, in which it exists in combination with the alkali morphia. It was first noticed by Seguin in 1804, and a few years after, more particularly described by Sertuerner, who named it *mecon* (*μῆκων*), poppy. Meconate of lime is one of the results of a peculiar process for obtaining morphia from opium: this is put into ten times its weight of water at 200°, and hydrochloric acid is added until it is dissolved; the solution is to be filtered, and on cooling it deposits limeconate of lime in the state of light, scaly, or acicular crystals; these are again to be dissolved in hot and very dilute hydrochloric acid, which separates the remainder of the lime, and on cooling, the meconic acid crystallizes. They are to be freed from colouring matter by subsequent treatment, and meconic acid has then the following properties: it acts on litmus paper, and has a sour taste; it is soluble in four times its weight of water, and also in alcohol. The crystals do not alter by exposure to the air, but when heated to 212° they lose 21.5 per cent. of water, and become opaque. Although when heated even to near 250° the acid is not totally decomposed, yet the boiling solution gives out carbonic acid gas, and a brown substance is formed which is metameconic acid. When strongly heated, it is totally vaporised and decomposed. When mixed with a solution of chloride of gold, and heated, it is decomposed, and metallic gold is precipitated; this acid possesses the characteristic property of forming a purplish-red coloured solution with the persalts of iron, and this is regarded as one of the best tests of its presence, and also of that of the opium from which it is derived.

According to Liebig, meconic acid consists very nearly of

Two equivalents of Hydrogen	•	2
Seven equivalents of Carbon	•	42
Seven equivalents of Oxygen	•	56

Equivalent 100

The salts which contain this acid are called *meconates*. We shall briefly state the properties of the more important of them:—*Meconate of Ammonia* crystallizes in quadri-

lateral prisms, dissolves in one and a half times its weight of water, yields water when heated, and afterwards sublimes without decomposing. *Meconate of Potash* crystallizes in tables and leaves, contains water of crystallization, and is soluble in twice its weight of cold water. *Meconate of Soda* crystallizes in fine needles, which contain much water of crystallization, and are soluble in five times their weight of water. *Meconate of Lime* forms acicular crystals, which contain water of crystallization, and are soluble in eight times their weight of water. When the acid is in excess the salt crystallizes in prisms, and is difficultly soluble in water. *Meconate of Magnesia* when neutral is only slightly soluble, but the supersalt dissolves readily; it crystallizes in flattened needles, which are brilliant and transparent, and have an acid and bitter taste. *Meconate of Barytes* is slightly soluble in water. *Meconate of Iron* is a colourless and very soluble salt, which becomes red by exposure to the air, and more rapidly by the addition of nitric acid. The *Permeconate of Iron* is also a soluble salt, and is of a fine red colour, which is destroyed by heat, by sulphurous acid, and protoxide of tin: the remaining metallic meconates are not important.

Metameconic Acid.—It has been above mentioned that when a solution of meconic acid is heated to ebullition, that carbonic acid is evolved, and a brownish solution results; this consists of colouring matter and metameconic acid. When a meconate, as of potash or lime, is boiled with hydrochloric acid, no colouring matter results, and yet metameconic acid is formed.

This acid is soluble in sixteen times its weight of boiling water, and separates on cooling in hard anhydrous grains, which, like the meconic acid, redden the persalts of iron, but they differ from it in every other respect.

It is formed by the mere separation of carbonic acid, by subtracting one equivalent of which from meconic acid we obtain the acid in question:—

	H.	C.	O.
Meconic acid .	2	7	7
Carbonic acid .	—	1	2
Metameconic acid .	2	6	5

Its saline combinations have been but little examined.

Pyromeconic Acid is obtained by heating meconic acid, which yields about one-fifth of its weight. It is purified by pressure between folds of blotting paper, and crystallization from solution in water. It is fusible between 218° and 257°, and then flows like oil; it is entirely soluble at a moderate temperature, and is more soluble in alcohol even than in water. It turns the persalts of iron red, and its salts are generally soluble in water. It is formed by the separation of four equivalents of carbonic acid and one equivalent of water, from two equivalents of meconic acid, thus:

	H.	C.	O.
Two equivalents of Meconic acid .	4	14	14
Four equivalents of Carbonic acid .	—	4	8
One equivalent of Water .	1	—	1
Pyromeconic acid .	3	10	5

MECONIN, a neutral principle existing in opium, first noticed by Dablane, and more particularly examined by Couerbe. To obtain it, an infusion of opium, from which the morphin has been precipitated, is to be evaporated, and the crystallized matter, obtained after being pressed, is to be treated with boiling alcohol; the solution contains narceia and colouring matter, from which it is to be separated by subsequent operations.

The properties of meconin are, that it is colourless, inodorous, is at first tasteless, but afterwards acid; it is soluble in water, alcohol, and æther, and crystallizes well in any of them; the crystalline form is a six-sided prism with dihedral summits; it fuses at 194°, and is volatilized at 310°, without undergoing any change of properties. It is soluble in about 265 parts of cold water, and 20 of boiling water. Sulphuric acid gives it a fine green colour, while nitric acid by its action converts it into a peculiar crystalline matter. Chlorine renders it of a blood-red colour, forming mechloic acid. It does not act either as an acid or an alkali.

According to Couerbe it consists of—

Four equivalents of hydrogen	4	or	4.44
Nine equivalents of carbon	54		60.00
Four equivalents of oxygen	32		35.56
	90		100.

MEDAL. Numismatists have usually given the name of medals to those coins that have been struck or cast for particular purposes and on extraordinary occasions, in commemoration of victories, treaties, coronations, and similar important events, or in honour of remarkable persons; in distinction to those which have been issued and generally circulated as money.

The words *medaglia* and *medaglione* first occur in Italian writers, from whom the English and French have evidently taken their *medal* and *medaille*. The derivation seems to be from the Greek *μέταλλον* (metal); of which medals are always made.

A reference to medals, in connection with numismatics, has been made in the article on coins [COIN], to which a few observations must now be added respecting them independently of their relation to the general subject.

Though we have proof in the specimens that have reached our times that the ancients were not less successful in the medallie than in the other arts of design, it does not appear that works of this class were sought after and preserved with the care bestowed on productions of the sister arts. None of the classic writers give any account of collections of medals and coins among the Greeks, and it is not until a somewhat late period that we find any distinct notice of a taste for them arising in Italy. Augustus, according to Suetonius, was the first who showed any interest in the subject; he was in the habit of presenting to his friends medals of foreign countries and princes as valuable marks of his favour.

Greek medals and medallions are very rare, few being known of earlier date than the establishment of the Imperial power at Rome, and when Greece was under Roman dominion. Some of Sicily are not however so scarce; they are of very fine design and workmanship, and deserve the careful attention of the connoisseur. The design of the finest of these is a head, usually of Ceres, with spoils in the exergue, and on the reverse a Victory crowning a figure in a car. Many of great excellence and in high preservation are contained in our collection of coins in the British Museum. The Roman medallions differ from the Greek (we mean in this place Greek medals of the Imperial periods) in their greater substance or thickness. Those from the time of Julius Cæsar to Hadrian are very scarce, and are, in consequence both of their rarity and their quality, of high value. The larger bronze medallions of the ancients are often of exquisite workmanship, and the devices are uncommon. Some are composed of two sorts of metal; the centre being of copper, with a border or ring of compound metal running round it, or *vice versa*, the copper being the outside ring. It often happens that the inscriptions on these medals extend over both the metals.

Among the peculiarities which distinguish modern from ancient medals may be mentioned the introduction of portraits of illustrious characters who were not of princely or regal houses. It is remarkable that while busts are found of many celebrated poets, historians, and philosophers of antiquity, their portraits never occur on medals. When, after the long interval of darkness in which literature and art were enveloped, from the decline of the Roman empire to the seventh or eighth century, taste began again to appear, and, with the other arts, die-engraving revived, it was employed in transmitting to posterity the portraits of eminent individuals. Petrarch seems to have been the first who, in modern times, made coins subservient to the illustration of history and biography. The emperor Charles IV. had expressed a wish that he would write the lives of eminent men, and would place him among them. Petrarch boldly told the prince he would do so whenever his life and conduct merited it. It was after this that he presented to Charles a collection of gold and silver coins bearing the representations of distinguished men. Pinkerton says that Angelo Poliziano was the first writer who adduced medals as authorities for ancient orthography and customs. He refers in his 'Miscellanen,' written about the year 1490, to some coins in the Medici collection.

The earliest examples of modern medals and medallions seem to be of the fifteenth century, though there is one remarkable exception to this in a medal of David II., king of Scotland. It is of gold, and was probably executed during that prince's captivity in England some time between the years 1330 and 1370. From the fifteenth century there is a succession of medals in most European countries. A

gold medal of the council of Florence, dated 1439, is one of the earliest. A still earlier one, if the date 1415 is correct, is of John Huss; but some doubts have been entertained of its authenticity. Vittore Pisano, a painter of Verona, is celebrated as the restorer of the art at that period; but the medal alluded to of David of Scotland seems to prove it was practised before his time. Pisano's medals are very large and are all cast. They are usually inscribed 'Opus Pisani Pictoris.' It is curious that he should always refer to his being a painter while exercising a totally distinct branch of art.

The Papal medals are among the finest of a continued series. They commence properly with Paul II., who began to reign in 1464; those of pontiffs who lived prior to that date having been added to the collection by successors. Some of the medals of a later period are valuable examples of the art, in which great improvements took place under Alexander VI. His successors Julius II., Leo X., and Clement VII., had many of their medals designed by Raffaello and Giulio Romano, while Benvenuto Cellini and other distinguished artists were employed to engrave them. A German family, named Ermerani, or Hermerani, of eminence as medal engravers, settled in Italy about the middle of the seventeenth century, and executed many of the Papal medals. This talent was not, it appears, confined to the men of this family: Venuti says each of the daughters also produced a fine medal.

The German medals commence in 1453, and are very numerous. The Sicilian medals appear as early as 1501. The first modern satirical medal is of that time, and was published by Frederick II. against his adversary Ferdinand king of Spain. It bears on one side the head of Ferdinand, with the inscription FERDINANDVS R. AR. VETVS VULPES ORBIS; on the reverse a wolf carrying off a sheep, with JUGUM MEUM SUAVE EST ET ONUS MEUM LEVE. Many others might be mentioned of this description. The employment of medals for the conveyance of satire is not confined to the moderns. Examples of it occur among the Romans, but they are rare.

The Spanish medals begin in 1503. The earliest of Venice appear in 1509; and those of Denmark in 1516. The first Dutch medals seem to be of 1566, and they are remarkable for the elaborate views, maps, and plans that are engraved on many of them. It has been observed among the distinctions of ancient and modern medals, that in the former, when buildings are represented, the simple elevations only are given, while in the latter perspective views are exhibited. The Dutch indulged very freely in the satirical vein, and for which they eventually paid very dearly, as it contributed, in no small degree, to bring on them the whole hostile power of France under Louis XIV., who is said to have been highly exasperated at the publication of a medal in which Van Heubingen, the Dutch ambassador, was represented as Joshua (his name) arresting the progress of the sun, under which type the flatterers of Louis designated that monarch.

The French medals do not exhibit any remarkable excellence till this reign. The popularity of Louis XIV. gave an impulse to the art, and we find his entire life illustrated (with more respect however to the national glory and the prince's vanity than to historical truth) by medals; some of them are well designed and finely executed. The medallic history of Napoleon deserves notice in the series of medals of France. It is of great extent, and is, for the most part, honourable to French art.

The series of English coins and medals is one of the most perfect. The first medal is of 1480. It is of a large size, and is executed in the early Italian manner. On one side is a portrait with IO. KENDAL. RHODI. TURCUPELLARIUS; on the reverse the arms of Kendal, with the inscription, TEMPORE OBSIDIONIS TURCORUM. MCCCCLXXX. It was found in Knaresborough forest, but it is believed to be of foreign, probably Italian, workmanship. The next English medal is of the time of Henry VIII. It is of gold, and bears the king's portrait on one side, with an inscription on the reverse. The first coronation medal appears in the reign of Edward VI. The medals of Queen Mary are numerous, and very interesting from the devices they bear. The Scotch coronation medal of Charles I. is of gold, and was struck at Edinburgh. It is remarkable as being the first struck in Britain with a legend on the edge. Specimens of this medal in gold are very scarce. The medals of the Commonwealth and of Charles II. are by Simon. Those of

Queen Anne are interesting from their being charged with the achievements of the great duke of Marlborough. Soon after this a Genevese artist, of the name of Dassier, was employed upon the medals of the kings of England, and executed many portraits of royal and other illustrious characters.

The study of medals is, in its class, of great importance. It is indispensable to the historian and the antiquary, and hardly less valuable to the man of taste. To the former, medals often afford information that cannot be obtained by other means, in the inscriptions, legends, and allegories with which they are charged; while to the artist and connoisseur many of them offer not only exceedingly beautiful examples of art, but, if their authenticity can be depended on, a series of medals of any nation is one of the best authorities that can be consulted for the state of the arts of design of any particular period.

It would be an almost endless task to enumerate the works that have been written on medals. The earliest treatise on the subject is that of Eneas Vico. It is dated 1548. The publications of Pinkerton in two volumes, of Eckhel, an introduction to the study of medals by Millin, of Barthelémy, Mionnet, and others, may be consulted for general information; while, for a more extended acquaintance with the subject, reference must be made to the voluminous illustrations which have emanated from those who have described in detail the various celebrated public and private collections. Some remarks on the manner of engraving dies for medals and coins will be found in the article on Intaglio. [INTAGLIO.]

MEDALLION, a medal of an extraordinary size. Medallions were never used as current coin; whereas it is probable that medals were *sometimes* allowed to pass in circulation as money.

MEDALLION, in architecture, any circular or oval tablet bearing on it objects represented in relief, as figures, heads, animals, flowers, &c.

MEDE, JOSEPH, was born at Borden in Essex, in the year 1586. When only ten years old he lost his father, but his education was well provided for by his relations. While a boy at school he met accidentally with a copy of Bellarmine's Hebrew grammar, and soon gained a considerable acquaintance with that language. In 1602 he entered Christ's College, Cambridge, and took his degree of master of arts in 1610. At this time his learning is spoken of as extraordinary. During the earlier part of his residence at college he is said to have been troubled with sceptical opinions, which however he soon shook off. His first work was a treatise, 'De Sanctitate Relativa,' addressed to Dr. Andrews, bishop of Ely, which procured for him the patronage of that prelate, who requested him to become his domestic chaplain. This offer Mr. Mede declined, and was soon after made a fellow of his college and reader of the Greek lecture of Sir Walter Mildmay's foundation. He appears to have been remarkably skilful and successful as a tutor.

In 1618 he took his degree of B.D. He refused the provostship of Trinity College, Dublin, which was twice offered him, in 1627 and 1630, through the influence of archbishop Usher. The extent of his ambition seems to have been to pursue his studies without interruption in the retirement of his college. There he spent the remainder of his life, and died in 1638, in his fifty-second year.

Mr. Mede was distinguished for his meekness, modesty, and prudence, and his liberality was such that he devoted the tenth of his scanty income to charitable uses. His learning was diversified and profound. In his younger years he studied astrology, but afterwards abandoned the pursuit. He was well acquainted with mathematics, medicine, and the various branches of philosophy, and was deeply versed in history and antiquities, and in the literature and sciences of the East, into the abstrusest parts of which he searched for illustrations of the prophecies of Scripture.

His chief work is the 'Clavis Apocalyptica,' containing a system for explaining the Apocalypse, which has been followed more or less by nearly all subsequent writers on the prophecies, and is recommended by bishop Hurd in his tenth sermon on the study of the prophecies, as being the first rational attempt to explain the Apocalypse. This work has been translated by Mr. T. Bransby Cooper, 8vo., Lond., 1833.

Mede's whole works were collected after his death by Dr. Worthington, in one vol. fol., Lond., 1672, with a life of the

author prefixed. There is also a recent edition of his 'Apostasy of the Latter Times,' 12mo., Lond., 1836.

MEDE'A. (Zoology.) [CILIOPADA, vol. vii., p. 165.]

ME'DIA (Μῆδια, ἡ), a country of ancient Asia. It is difficult to determine its boundaries, as they differed at various times. In the time of Strabo it was divided into two divisions, Great Media and Media Atropatene. Great Media, which is a high table-land, is said by all ancient writers to have had a good climate and a fertile soil; an account which is fully confirmed by modern travellers. It was separated on the west and south-west from the low country, watered by the Tigris and Euphrates, by a range of mountains known to the ancients under the name of Zagros and Parachoatras. Xenophon however appears to include in Media all the country between the Tigris and Zagros. (*Anab.*, ii. 4, § 27.) On the east it was bounded by a desert and the Caspian mountains (the modern Elburz mountains); and on the north and north-west by the Cadusii, Atropatene, and the Matieni, thus answering for the most part to the modern Irak Ajemi. Atropatene, which corresponds to the modern Azerbaijan, extended as far north as the Araxes (Aras); it was much less fertile than Great Media, and does not appear to have been included in the Media of Herodotus. It derived its name from Atropates, who successfully opposed the Macedonians, and established an independent monarchy, which continued till the time of Strabo (p. 522, 523, Casaubon), notwithstanding its proximity to the Armenian and Parthian dominions.

The principal town of Great Media was Agbatana, or Ecbatana (Hamadan), the summer residence of the Persian kings. [ECBATANA.] South-west of Ecbatana was Baptana, or Bagistana [BESITTOON], situated on the great commercial road which, beginning at Ctesiphon, passed through the Median gates of the mountain-range called Zagros, and terminated at Ecbatana. This commercial road, which is determined by the physical character of the country, has continued in use to the present day. In the north-east of Great Media, near the Caspian gates, was the town of Rhagæ, afterwards called Europus by the Macedonians, and Arsacia by the Parthians, which was founded, or rather colonized, by the Macedonians under Seleucus Nicator. (Strabo, p. 524.) This town, of which the ruins are still visible at Rai, is frequently mentioned in the apocryphal book of Tobit, as the place where many of the Jews resided, who had been carried away captive by Shalmaneser. There are several passes through the Elburz mountains, to the south-east of Tehran, in the neighbourhood of Rai. Near Rhagæ was the Nisæan plain, celebrated for its breed of horses, which were considered in ancient times the best in Asia. Arrian informs us that there were 50,000 horses reared in this plain in the time of Alexander, and that there were formerly as many as 150,000. (Herodot., iii. 106, vii. 40; Arrian, vii. 13; Strabo, p. 525; Ammian., xxiii. 6.)

The mountainous country in the south-western part of Great Media was inhabited by several warlike tribes, who maintained their independence against the Persian monarchy. Strabo mentions four tribes in particular (p. 524): the Mardi, bordering on the north-west of Persis; the Uxii and Elymæi, east of Susiana; and the Cossæi, south of Great Media. The king of Persia was obliged to pass through the country of the latter whenever he visited Ecbatana, and could only obtain a free passage by the payment of a considerable sum of money. The Cossæi were defeated by Alexander, but they never appear to have been completely subdued by the Macedonians.

The chief town of Atropatene was Gaza, or Gazika, as it is called by Ptolemy, at no great distance from the modern Tauris, or Taubreez. North-west of Gaza was a salt lake, called Spauta, or Martianus (Shabec, or Ourmia). In the north-east of Atropatene, near the Caspian Sea, there were many nomad tribes, which appear to have formed no part of the Median nation. The most powerful of these tribes were the Kadusii, or Gelæ, whence the modern name of that part of the country (Ghilan) is probably derived.

According to Herodotus the Medes were originally divided into six tribes, the Busæ, Parataceni, Struchates, Arizanti, Budii, and Magi (i. 101). They were originally called Arii (Herodot., vii. 62); which word appears to contain the same root as Ar-tæi, the ancient name of the Persians (Herodot., vii. 61). It is not improbable that this name was originally applied to most of the Indo-Germanic nations. Tacitus

speaks of the Arii as one of the most powerful of the German tribes (*German.*, 43); and India proper is called, in the most ancient Sanskrit works, Arrya-varia, 'holy land.' The same name was retained in the province of Ariana, and is still employed in the East as the proper name of Persia (Iran).

Media originally formed part of the Assyrian empire, but its history as an independent kingdom is given so differently by Herodotus and Ctesias (whose account is preserved in Diodorus), as to render it probable that the narrative of Ctesias must refer to a different dynasty in eastern Asia. Ctesias makes the Median monarchy last 282 years; and as Media was conquered by Cyrus about B.C. 560, it follows that the Median monarchy would commence, according to his account, about B.C. 842. Herodotus, on the contrary, assigns to the Median monarchy a period of 128 years, which, including the 28 years during which the Scythians had possession of the country, would place the commencement of the Median monarchy B.C. 716. The founder of the Median monarchy was Arbaces, according to Ctesias, who reckons eight kings from him to Astyages.

According to the account of Herodotus there were four kings of Media: 1, Deioees, who reigned B.C. 710-657. 2, Phraortes, B.C. 657-635, greatly extended the Median empire, subdued the Persians, and many other nations, but fell in an expedition against the Assyrians of Ninus (Nineveh). 3, Cyaxares, B.C. 635-595, completely organised the military force of the empire, and extended its boundaries as far west as the Halys. In an expedition against Nineveh, he was defeated by the Scythians, who had made an irruption into southern Asia, and was deprived of his kingdom for 28 years. After the expulsion of the Scythians, he took Nineveh, and subdued the Assyrian empire, with the exception of the Babylonian district (Βαβυλωνίης μοίρης). 4, Astyages, B.C. 595-560, who was dethroned by his grandson Cyrus, and Media reduced to a Persian province. The history of the rise of the Persian monarchy is related very differently by Xenophon, who also makes a fifth Median king, Cyaxares II., succeed Astyages.

The Medes revolted during the reign of Darius II., the father of the younger Cyrus, about B.C. 408, but were again subdued. (Herodot., i. 130; Xenoph., *Hellen.*, i. 2, § 19.) They do not appear after this time to have made any further attempt at recovering their independence. On the downfall of the Persian empire they formed a part of the kingdom of the Seleucidæ, and were subsequently subject to the Parthians.

ME'DICI, FAMILY OF. The early history of the family of the Medici is obscure, although some authors have traced their genealogy from the age of Charlemagne. But it must be remembered that these genealogies were made after the elevation of this family to supreme power in Florence. It appears however, from authentic monuments, that many individuals of this family had signalled themselves on various important occasions. Giovanni de' Medici, in the year 1251, with a body of only one hundred Florentines, forced his way through the Milanese army, then besieging the fortress of Scarparia, and entered the place with the loss of twenty lives. Francesco de' Medici was at the head of the magistracy of Florence in 1348, at the time when the black plague, which had desolated so large a portion of the world, extended its ravages to that city. Salvestro de' Medici acquired great reputation by his temperate but firm resistance to the nobles, who, in order to secure their power, accused those who opposed them of being attached to the party of the Ghibelines, then in great odium at Florence. The persons so accused were said to be *ammoniti* (admonished), and by that act were excluded from all offices of government. In the year 1379, Salvestro, being chosen chief magistrate, exerted his power to reform this abuse, which was not however effected without a violent commotion, in which several of the nobility lost their lives. After the death of Salvestro, his son, Veri de' Medici, continued to hold a high rank in the republic, and was in great favour with the populace.

The founder however of that greatness which his posterity enjoyed for several ages was Giovanni de' Medici, the great-grandfather of Lorenzo the Magnificent. By a strict attention to commerce, he acquired great wealth; by his affability, moderation, and liberality, he ensured the confidence and esteem of his fellow-citizens. Without seeking after the honours of the republic, he was honoured with them all. The policy by which the house of Medici attained

its political power is indicated in the charge given by this venerable old man on his death-bed to his two sons, Cosmo and Lorenzo: 'I feel,' said he, 'that I have lived the time prescribed me. I die content; leaving you, my sons, in affluence and in health, and in such a station, that whilst you follow my example, you may live in your native place honoured and respected. Nothing affords me more pleasure than the reflection that my conduct has not given offence to any one; but that, on the contrary, I have endeavoured to serve all persons to the best of my abilities. I advise you to do the same. With respect to the honours of the state, if you would live with security, accept only such as are bestowed on you by the laws and the favour of your fellow-citizens; for it is the exercise of that power which is obtained by violence, and not of that which is voluntarily given, that occasions hatred and contention.' He died in the year 1428, leaving two sons, Cosmo, born in the year 1389, and Lorenzo in 1394, from the latter of whom is derived the collateral branch of the family, which in the beginning of the sixteenth century obtained the absolute sovereignty of Tuscany.

Even in the life-time of his father, Cosmo had engaged not only in the extensive business by which the family had acquired its wealth, but also in the affairs of state. Such was his authority and reputation, that in the year 1414, when Balthasar Cossa, who had been elected pope, and had assumed the name of John XXIII., was summoned to attend the council of Constance, he chose to be accompanied by Cosmo de' Medici, among other men of eminence, whose characters might countenance his cause. By this council, which continued nearly four years, Balthasar was deprived of his pontifical dignity, and Otto Colonna, who took the name of Martin V., was elected pope. Cosmo did not desert in adversity the man to whom he had attached himself in prosperity. At the expense of a large sum of money, he redeemed him from the hands of the duke of Bavaria, who had seized upon his person; and afterwards gave him an hospitable shelter at Florence during the remainder of his life. The successful pontiff, instead of resenting the kindness shown to his rival, soon afterwards paid a public visit to Florence, where, on the formal submission of Balthasar, and at the request of the Medici, he created him a cardinal, with the privilege of taking the first place in the sacred college. The new-made cardinal died in 1419, and it was rumoured that the Medici at his death possessed themselves of immense wealth which he had acquired during his pontificate. This rumour was afterwards encouraged by those who well knew its falsehood. The true source of the wealth of the Medici was their superior talents and application to business, and the property of the cardinal was scarcely sufficient to discharge his debts and legacies.

The authority which Cosmo and his descendants exercised in Florence, during the fifteenth century, consisted rather in influence than in any definite power. Cosmo exerted this influence with great prudence, yet owing to the discontent of the Florentines with the result of the war against Lucca, a party arose, headed by Rinaldo de Albizi, which, in 1433, after filling the magistracies with their own adherents, seized Cosmo, and committed him to prison. He was afterwards banished to Padua for ten years, and several other members and friends of the Medici family were treated in the same way. From Florence Cosmo proceeded immediately towards Venice, where he was received with marked respect by the government; and after a short stay there he went to Padua. Upon an application to the Florentine state by Andrea Donato, the Venetian ambassador, it was consented to that he might reside on any part of the Venetian territories, but not to approach within one hundred and seventy miles from Florence. The affectionate reception which he had met with at Venice induced him to fix his abode there. Within a year of Cosmo's retreat, Rinaldo was obliged to quit Florence; and Cosmo was recalled, and returned amidst the acclamations of the people. The gonfaloniere, or standard-bearer, the executive officer who had pronounced his sentence, with a few others of his party, were put to death on the occasion. Measures were now taken to restrict the choice of magistrates to the partisans of the Medici, and alliances were formed with the neighbouring powers for the purpose of supporting and perpetuating the new system of administration in Florence. The subsequent life of Cosmo de' Medici was an almost uninterrupted course of prosperity. The tranquillity enjoyed by the republic, and the satisfaction which he experienced in the esteem and confidence of

his fellow-citizens, enabled him to indulge his taste for the promotion of science and the encouragement of learned men. Though a private citizen, he surpassed almost all the princes of Europe in his munificent patronage of literature and the fine arts. He assembled round him some of the most learned men of the age, who had begun to cultivate the Greek language and philosophy. He established at Florence an academy expressly for the explanation of the Platonic philosophy, at the head of which he placed the celebrated Marsilius Ficinus. By means of foreign correspondence, he collected the Greek, Latin, and Oriental MSS., which formed the basis of the Laurentian library; nor was he less liberal in his encouragement of the fine arts. During the retirement of his latter days, his happiest hours were devoted to the study of letters and philosophy, and the conversation of learned men. He also endowed numerous religious houses, and built an hospital at Jerusalem for the relief of distressed pilgrims. The spirit of his administration was moderate, he avoided all appearance of state which might excite the jealousy of the Florentines; and, by way of increasing his interest among them, he confined the marriages of his children to Florentine families. By this prudent conduct and his benevolence, he acquired the title of 'father of his country,' which was inscribed upon his tomb; an appellation which, as it was founded on real merit, has ever since been attached to the name of Cosmo de' Medici. He died August 1st, 1464. Cosmo de' Medici married Contesina Bardi, of a noble and illustrious family, which had been long distinguished at Florence. By her he had two sons, Giovanni and Piero; and he had a natural son by a mistress.

Giovanni de' Medici was one of the Florentine ambassadors who were sent, in 1455, to take the necessary oaths to Calixtus III., who had succeeded Nicholas V. He was Cosmo's favourite son, on whom all his future hopes and expectations rested; but he died prematurely in 1463. Giovanni married Cornelia de Alessandri, by whom he had only one son, who died an infant. Piero de' Medici succeeded to Cosmo's fortune and authority at Florence: Cosmo, in the decline of life, had recommended to his surviving son to employ one Diotisalvi Neroni as his minister, whom he believed to be attached to the Medici interests; but the ambition of Neroni, and the disaffection of some former friends of the Medici, had nearly proved fatal to Piero's administration. It was the intention of the conspirators to surprise Piero at one of his country residences; but one of the conspirators went and communicated the plot to him. Piero, by an expeditious return to the city, at the head of a chosen troop of his friends, baffled the designs of his enemies. Most of the conspirators saved themselves by flight: and though, with the assistance of the Venetians, they afterwards made a stand, they were finally compelled to evacuate Tuscany. Piero died Dec. 3, 1469, leaving by his wife, Lucretia Tornabuoni, two sons and two daughters, Lorenzo, Giuliano, Bianca, and Giovanna.

At the death of Piero de' Medici, his two sons inherited his property; but Lorenzo succeeded him as head of the republic, and upon him the title of Magnificent was afterwards conferred. From the time of Cosmo's death, in 1464, on account of the infirmities of his father, Lorenzo had been introduced to a knowledge of public affairs, although then only in his sixteenth year. With this view he was sent to visit the principal courts in Italy. Upon the accession of Sixtus IV. to the papal throne, he went, with other citizens of Florence, to congratulate the new pope, and was invested with the office of treasurer of the holy see; and while at Rome took every opportunity to add to the remains of ancient art which his family had collected. One of the first events after he undertook the administration of affairs was a revolt of the inhabitants of Volterra, on account of a dispute with the Florentine republic. By the recommendation of Lorenzo, force was used, and the result was the sack of Volterra. In 1472 he re-established the academy of Pisa, to which city he removed in order to complete the undertaking: he selected the most eminent professors, and contributed a large sum from his private fortune, in addition to that granted by the state of Florence. Lorenzo, who was, or affected to be, an admirer of Plato, took an active part in the establishment of an academy for the cultivation of the Platonic philosophy, and instituted an annual festival in honour of Plato. Whilst Lorenzo was thus dividing his time between the administration of the state and the promotion of literature, the Pazzi,

a numerous and distinguished family in Florence, formed a conspiracy to assassinate Lorenzo and his brother. Giuliano was killed, but Lorenzo escaped. The people, who were attached to the Medici, collecting in great numbers, put to death or apprehended the assassins. Salviati, archbishop of Pisa, was hung through the windows of the palace, and was not allowed to divest himself even of his robes; and Jacopo de' Pazzi, with one of his nephews, shared the same fate. The name and arms of the Pazzi family were suppressed, its members were banished, and Lorenzo rose still higher in the esteem and affection of his fellow citizens. Sixtus IV., who was a party to this conspiracy, excommunicated Lorenzo and the magistrates of Florence, laid an interdict upon the whole territory, and, forming a league with the king of Naples, prepared to invade the Florentine dominions. Lorenzo appealed to all the surrounding potentates, and he was zealously supported by his fellow-citizens. Hostilities were commenced, and carried on for two campaigns. At the close of 1479, Lorenzo took the bold resolution of paying a visit to the king of Naples, and, without obtaining any previous promise of security, trusted himself to the mercy of his enemy. The result of this confidence was a treaty of mutual defence and friendship between the king of Naples and Florence, and Sixtus afterwards consented to a peace. The death of Sixtus IV. freed Lorenzo from a dangerous enemy, and he found a friend in his successor Innocent VIII. Lorenzo now secured to the republic of Florence a degree of tranquillity and prosperity which it had scarcely ever known before; and by procuring the institution of a deliberative body, of the nature of a senate, he corrected the democratical part of its constitution.

Lorenzo distinguished himself above all his predecessors by the encouragement of literature and the arts. His own productions are sonnets, canzoni, and other lyric pieces; some longer works in stanzas, some comic satires, carnival songs, and various sacred poems. Many of the lighter kind were popular in their day. Although the ancestors of Lorenzo laid the foundation of the immense collection of manuscripts contained in the Laurentian library, Lorenzo has the credit of adding most largely to the stock. For the purpose of enriching his collection of books and antiquities, he employed learned men in different parts of Italy, and especially his intimate friend Politian, who made several journeys in order to discover and purchase the valuable remains of antiquity. Two journeys were undertaken at the request of Lorenzo into the East by John Lascaris, and the result was the acquisition of a great number of manuscripts. On his return from his second expedition, Lascaris brought two hundred MSS., many of which he had procured from a monastery at Mount Athos; but this treasure did not arrive till after the death of Lorenzo, who in his last moments expressed to Politian and Pico of Mirandola his regret that he could not live to complete the collection which he was forming. On the discovery of the art of printing, Lorenzo quickly saw and appreciated its importance. At his suggestion, several Italian scholars devoted their attention to collating the manuscripts of the antient authors, for the purpose of having them accurately printed. On the capture of Constantinople by the Turks, many learned Greeks took refuge in Italy; and an academy was established at Florence for the purpose of cultivating the Greek language, partly under the direction of native Greeks, and partly under native Italians. The services of these learned men were procured by Lorenzo, and were amply rewarded by his bounty. 'Hence,' as Roscoe observes, 'succeeding scholars have been profuse of their acknowledgements to their great patron, who first formed that establishment, from which (to use their own scholastic figure), as from the Trojan horse, so many illustrious champions have sprung, and by means of which the knowledge of the Greek tongue was extended, not only through Italy, but through France, Spain, Germany, and England, from all which countries numerous pupils attended at Florence, who diffused the learning they had there acquired throughout the rest of Europe.'

Lorenzo also augmented his father's collection of the remains of antient art. He appropriated his gardens in Florence to the purpose of an academy for the study of the antique, which he furnished with statues, busts, and other works of art, the best in their kind that he could procure. The higher class of his fellow-citizens were incited to these pursuits by the example of Lorenzo; and the lower class

by his liberality. To the latter he not only allowed competent stipends while they attended to their studies, but gave considerable premiums as rewards of their proficiency. To this institution, more than to any other circumstance, Roscoe ascribes the sudden and astonishing advance which, toward the close of the fifteenth century, was evidently made in the arts, and which, commencing at Florence, extended itself to the rest of Europe. In 1488 Lorenzo lost his wife; and on the 8th of April, 1492, he sunk under a slow fever, and expired in the forty-fourth year of his age. Leoni of Spoleto, his physician, a person of great eminence in his profession, is said to have hastened his death by mistaking his case.

By his wife, Clarice Orsini, Lorenzo had a numerous family: three sons (Piero, Giovanni, and Giuliano) and four daughters arrived at the age of maturity. Piero was born Feb. 15th, 1471, Giovanni in 1475, and Giuliano in 1478. Giovanni was afterward known under the name of Leo X.; and Giuliano, having allied himself by marriage to the royal house of France, became Duke of Nemours.

Of Giuliano, the brother of Lorenzo, Roscoe preserves an interesting anecdote. Shortly after the attempt at assassination, he says, 'Lorenzo received a visit from Antonio da San Gallo, who informed him that the untimely death of Giuliano had prevented his disclosing to Lorenzo a circumstance with which it was now become necessary that he should be acquainted: this was the birth of a son, whom a lady of the family of Gorini had borne to Giuliano about twelve months before his death, and whom Antonio had held over the baptismal font, where he received the name of Giulio. Lorenzo immediately repaired to the place of the infant's residence, and, taking him under his protection, delivered him to Antonio, with whom he remained until he had arrived at the seventh year of his age. This concealed offspring of illicit love, to whom the kindness of Lorenzo supplied the untimely loss of a father, was destined to act an important part in the affairs of Europe. The final extinction of the liberties of Florence, the alliance of the family of Medici with the royal house of France, the expulsion of Henry VIII. of England from the bosom of the Roman Church, and the consequent establishment of the doctrines of the reformers in this island, are principally to be referred to this illegitimate son of Giuliano de' Medici, who through various vicissitudes of fortune at length obtained the supreme direction of the Roman see, and under the name of Clement VII. guided the bark of St. Peter through a succession of the severest storms which it has ever experienced.'

Piero, the eldest son of Lorenzo, succeeded him in the administration of Florence. Politian said that his father had a favourable opinion of his capacity, but it soon appeared that he was unequal to the task of government. With the view of obtaining the sovereign power at Florence, he formed a more intimate connection with the pope and the king of Naples. On the entrance of the French into Italy under Charles VIII. he deserted his allies. As soon as the French king reached the confines of the Florentine state, Piero had a secret interview with him, in which he was lavish in his offers to promote the interest of the king, and as a pledge of his fidelity surrendered to him the important fortress of Sarzana, with the town of Pietra Santa, and the cities of Pisa and Leghorn. Charles undertook to restore these places as soon as he had accomplished the conquest of the kingdom of Naples. On his return to Florence after this disgraceful compromise, Piero was refused admittance into the palace of the magistrates, and, finding the people were so highly exasperated against him as to endanger his personal safety, he hastily withdrew himself from his native place to Venice. The miseries which the inhabitants of Italy experienced in consequence of the French invasion belong to the general history of Italy. The plundering of the palace of the Medici, and the dispersion of that invaluable library which had been collected by the care of the Medici, were among the misfortunes that befel Florence. The French troops, which had entered the city without opposition, led the way to this act of barbarism, in which they were joined by the Florentines themselves, who openly carried off or purloined whatever they could discover that was rare or valuable. Besides the numerous manuscripts, the plunderers carried off the inestimable specimens of the arts which the palace of the Medici contained, and which had long made it the admiration of strangers and the chief ornament of the city. Exquisite pieces of antient

sculpture, vases, cameos, and gems of various kinds, were lost amidst the indiscriminate plunder, and the rich accumulations of half a century were destroyed or dispersed in a single day.

The subsequent history of Piero was a continual succession of mortifications and disappointments. In 1504, when Italy was invaded by Louis XII., Piero entered into the service of the French, and was present at the engagement in which they were defeated by the Spaniards with great loss, upon the banks of the Garigliano. In effecting his escape he attempted to pass the river; but the boat in which he, with several other men of rank, had embarked, being laden with heavy cannon, sunk in the stream.

Of the subsequent restoration of the Medici to Florence, an account is given in the life of Leo X., as well as, under Cosmo I., of the assassination of Alessandro, and the final extinction of the republic, when Cosmo was elevated to the rank of duke of Florence, and afterwards to that of grand-duke of Tuscany. For more minute details of the house of Medici, the several works may be consulted from which this notice has been chiefly derived.

(*Modern Universal History*, 8vo., vol. xxxvi.; Noble's *Memoirs of the House of Medici*, illustrated with genealogical tables; Tenhove's *Memoirs of the House of Medici*, translated from the French by Sir R. Clayton, 2 vols. 4to., Bath, 1797; Roscoe's *Life of Lorenzo de' Medici*, 2 vols. 4to., Lond., 1796; and his *Life and Pontificate of Leo X.*, 4 vols. 4to., Liverp., 1805.)

The genealogy of the Medici to the present time is given in a splendid work but little known, entitled 'Famiglie celebri Italiane,' di P. Litta, still in progress. The Medici and their descendants are comprised in 'Fascicolo XVII,' in seven parts, folio, Milan, 1827-30.

MEDICINE. The earliest records of the practice of medicine are extremely obscure. Among the Jews it appears to have been entirely confined to the priests, and the whole art seems to have consisted in the prevention of contagion by isolation and cleanliness, and the administration of a few uncertain remedies. The Egyptians, according to the account of Herodotus, must have made some little progress; purging medicines and emetics were well known to them and much used; and such was the subdivision of labour, that there were physicians for every separate complaint, some for the eyes, others for the head, others for the teeth, others for the abdominal parts, and others for diseases which did not manifest themselves by outward visible symptoms. (Herod., ii. 84.) It appears however that in the time of Darius the son of Hystaspes, the Greeks possessed at least more skill than the Egyptians. (Herod., iii. 129.) The Greeks probably derived their knowledge of medicine, with that of many other arts, from Egypt, whence Chiron, the Centaur of their fables, is said to have first introduced it among them. His pupil Æsculapius [ÆSCULAPIUS] so much improved the art, that he was deified; and Machaon and Podalirius, his sons, accompanied the Grecian army to the siege of Troy. From circumstances mentioned in the 'Iliad,' it would appear that their practice was almost entirely confined to the treatment of wounds, and that charms and incantations formed a considerable portion of the means which they employed. The descendants of Æsculapius were for many years the chief practitioners of medicine: they were called Asclepiads, and were the priests of the temples erected in honour of their progenitor, to which the sick were accustomed to resort for advice and the application of remedies.

In the sixth century before the Christian æra, medicine, with other sciences, began to be more philosophically studied in Greece, and among the first of those who devoted much of their time to the investigation of the structure and functions of the animal body was Pythagoras. His pupils Democritus and Heraclitus appear also to have added considerably to the knowledge both of anatomy and of practical medicine, and their contemporary Herodicus first introduced the practice of gymnastic exercises, which afterwards formed so large a part of medical treatment. [GYMNASTICS.] But the most remarkable man in the history of medicine in Greece was Hippocrates, one of the Asclepiads, who was born at Cos (where one of the chief temples was erected), B.C. 460, and was the pupil of Heraclitus and Herodicus. [HIPPOCRATES.] The improvements which he made in medicine (and many of which are detailed in the article referred to) were so considerable, that for many centuries his successors appear to have been content to follow him in

P. C., No. 919.

reverential imitation. His sons Thessalus and Draco, and his son-in-law Polybius, were the most renowned of his descendants, and they are generally regarded as the founders of the medical sect or school which was called the Hippocratean or Dogmatic sect.

The establishment of the Alexandrian school of philosophy forms the next most important epoch. The science of medicine was assiduously cultivated, and the human body was first dissected in Alexandria by Erasistratus and Herophilus. [HEROPHILUS.] The former was the pupil of Chrysippus, a violent opponent of the Hippocratic school, and a bold innovator in medicine, with whom probably originated the schism in consequence of which, for some centuries, every physician ranged himself in one of two sects, the Dogmatists and the Empirics. The Dogmatists held that disease could not be securely treated, except on the foundation of a knowledge of the health structure and actions of the body, and of the influence of remedies, and the effects of disease upon it; while the Empirics maintained that such knowledge was not only unnecessary, but unattainable, and that simple experience should be the only guide to practice. The progress of the science was greatly arrested by the observation of facts being neglected in the ardour with which each party argued its own cause, and the dispute only seemed to cease with the introduction of a new sect.

During the early periods of the Roman empire medicine seems to have been little cultivated, and, according to Pliny (xxix. 1), Rome was for 600 years without professed physicians, though not entirely without medical knowledge. The first individual of any eminence who practised medicine in Rome was Asclepiades of Bithynia [ASCLEPIADES], who lived in the century before the commencement of the Christian æra; but he does not appear to have advanced the knowledge of the science. He was succeeded by his pupil Themison, the founder of a sect called Methodics, who held doctrines nearly intermediate between those of the Dogmatists and of the Empirics. A large majority of succeeding physicians attached themselves to this sect, and among them were Soranus and Aurelianus, whose writings are the principal that remain of this period.

About two centuries later the Methodics were divided into numerous sects, as the doctrines of particular physicians became more generally received. The chief of these sects were the Pneumatics and the Eclectics. The former are represented by their most eminent writer, Aretæus [ARETÆUS], who lived in the reign of Vespasian, and the chief points of their doctrines are detailed in his life. Of the Eclectics, the most celebrated was Archigenes, of Apamea, who practised at Rome in the time of Trajan. But the most remarkable writer of this age was Celsus, in whose work, 'De Medicinâ,' the progress and condition of medicine previously to and during his life are amply detailed. [CELSUS.] He was the first native of Rome who is known to have studied medicine, and the only one who did so with success. In his time medicine, which, as a science, might be said to have had its origin with Hippocrates, had made considerable progress; the several sects of its professors differed rather in their pretensions than in any important point of knowledge; the philosophical learning, which some sought, and others despised, was almost entirely hypothetical, and had relation only to the doctrines of the mutual actions of imaginary atoms, elements, and spirits, but all had been alike engaged in the study of practical medicine, and their accumulated experience had by this time formed a very considerable amount of useful knowledge.

The individual whose history forms the next chief epoch in the history of medicine is Galen; but it will be unnecessary to repeat what has already been said of his doctrines and practice. [GALEN.] For a long time after his death physicians were chiefly occupied in commenting on his works, and imitating, as closely as they could, his practice. His writings were regarded as ultimate authority, and everything that seemed opposed to them was at once rejected. From the time of Galen to the seventh century the only names of any repute (and theirs is but small) are Sextus Empiricus, Oribasius, Ætius, Alexander Trallianus, and Paulus of Ægina; and after the death of the last of these, no medical work of the least merit was published in the Greek language.

From the seventh to the twelfth century the only nation in which medicine made any progress, or was even prevented from retrograding, was the Arabian. It appears that in

VOL. XV.—I

the conquest of Alexandria some books were saved from the burning of its magnificent library, and that among them were the writings of Hippocrates and Galen. The latter were soon translated into Arabic and diligently studied; and all the earliest Arabian works on medicine, as those of Ahrun in the eighth, and Serapion in the ninth century, are little more than transcripts of those of Galen. One of the most illustrious of the Arabian school was Rhazes, who was born in the ninth century, and whose works contain many original observations, of which the most remarkable relate to some important diseases, unknown to, or at least not described by former writers, as smallpox and measles. In those parts of his writings which relate to pharmacy Rhazes describes some of the earliest of what are called chemical remedies, which were doubtless suggested by the recent origin of the systematic practice of chemistry among his countrymen. After Rhazes was Ali-Abbas, and after him Avicenna, who attained the highest repute of all. He was born in 980, and has left voluminous writings, which however appear to show that his fame is deserved only when he is placed in comparison with his contemporaries. Neither Avicenna nor the later writers, Mesue and Albucasis, contributed anything of importance to the progress of medicine. Avenzoar and Averroes were disciples of the Arabian school, and, though natives of Spain, wrote in the Arabic language. The former was the preceptor of the latter, and lived in the eleventh century, and his works are among the few that exhibit even slight departures from the doctrines of Galen. The circumstances which chiefly mark the period of the Arabian school of medicine are, the more correct description of several diseases, the first records of some new and important ones, and the introduction of several valuable remedies, both from the vegetable productions of the tropical and oriental countries, and from the chemical processes which were then first brought into general use. But the physicians adhered too carefully to the doctrines of Galen to make much progress in their science; and anatomy, physiology, and pathology appear to have been almost entirely neglected.

From the decline of the Arabian school in the twelfth century to the beginning of the fifteenth, the history of medicine presents few circumstances of interest. The dissection of the human body was first publicly practised by Mondini at Bologna, about the year 1315; and at about the same time lived Gilbert, the first English writer on medicine who acquired any repute. Between the twelfth and fifteenth centuries several of the most important universities were founded, with a school of medicine attached to each: that of Salerno was established in the twelfth century, that of Montpellier in the thirteenth, those of Bologna, Vienna, and Paris in the fourteenth, and in the fifteenth those of Rome, Padua, Pavia, and several other cities in Italy. By means of these, and by the impetus which, with all other sciences, it received from the invention of printing, medicine again commenced a forward course. In this country it derived the greatest advantages from Linacre [LINACRE] and the establishment of the college of physicians, to whose members, in succeeding years, several of the most brilliant discoveries are due.

In the fifteenth century the sect of chemical physicians arose, and their doctrines, under the bold advocacy of Paracelsus, who publicly burnt the writings of Galen, obtained considerable credit and numerous supporters. Their main assertion was that the operations of the living body are entirely governed by the same chemical laws as obtain in inorganic matter; and the works of all the writers of the fifteenth century are filled with arguments in support either of this doctrine or of the more ancient tenets of Galen. The Galenists were of course the more learned party, who were well versed in the ancient books; while the chemists were chiefly those who were more practically skilled in the arts of that newly discovered science. Neither party can be said to have much advanced the knowledge of medicine; but in the middle of the sixteenth century the most important improvement commenced in the diligent and accurate study of anatomy by Vesalius [VESALIUS], who, disregarding the general obloquy which he incurred, carefully studied the structure of the most important parts of the human body.

From the time of Vesalius, the study of anatomy was diligently pursued, and in the early part of the seventeenth century was rewarded by several of the most interesting and important discoveries; as that of the circulation by Harvey [HARVEY], of the absorbents by Asellius, of the process

of respiration by Malpighi [MALPIGHI], and numerous others. Among the most celebrated men of the seventeenth century, may be enumerated Glisson, Bartholin, Rudbeck, Fabricius, Hooke, Sylvius, Willis, Riolanus, Fallopius, and Bellini. All of them were employed in the diligent pursuit of anatomical and physiological knowledge; and, somewhat later, Sydenham again introduced a truly Hippocratic mode of observation of the phenomena of disease in its symptoms, causes, and effects, and in the influence of remedies upon it. By the combined efforts of the anatomists and the practical physicians, medicine in this century made the most remarkable progress, although it was in some measure checked by the attempted application of the laws of mechanics (then, from the discoveries of Newton and others, the dominant science) to the explanation of all the phenomena of the living body. The iatro-mathematicians, as those who supported this theory were called, were long engaged with the chemists, who had already conquered the Galenists; and to these rival sects was then added that of the Vitalists, founded by Van Helmont [HELMONT, VAN], which at last obtained complete ascendancy over both. The Vitalists held that there is in the living body a principle (upon which different members of the sect conferred different hypothetical appellations) which presides over and directs all the processes of the living body, and is directly opposed to the influence of chemical and mechanical agents. Stahl, Hoffmann, and Boerhaave were of this school, though each considerably modified the opinions of its founder.

Among the pupils of Boerhaave were Van Swieten and Haller. The former adopted the hypothetical spirit of the school too closely to add much of real value to medical science; but the latter may be fairly considered to have done more for it than any other single individual. Before the time of Haller, the cases of Harvey, Glisson, Malpighi, and others, who devoted themselves to the simple observation of facts and the evident deductions from them, were exceptional; but since his time, the exceptions have rather been those who, with a comparative neglect of observation, have endeavoured only to find or support some theory by which all the phenomena they met with might seem explained. Haller's contemporary Cullen [CULLEN], though he yielded much more to theory, was of eminent service in the study of practical medicine; and his opponent Brown is acknowledged to have introduced many useful lessons in the same branch of the study.

With the gradual oblivion of the hypotheses of both Cullen and Brown, the theoretical study of medicine may be considered to have entirely ceased, and in the present day we may certainly be said to be without any general medical theory. From the time of Haller, medicine has acquired more and more nearly the character of a science of simple observation and the patient investigation of facts. Its history would therefore consist of little more than a recital of successive discoveries, each perhaps small when compared with the vast amount of knowledge still unexplored, yet altogether so numerous that even a sketch of them could not be here introduced. The reader must therefore be referred to the several articles on the different branches of medicine and its collateral sciences, and to the lives of those who have been most conspicuous for their discoveries.

MEDICK, a corruption of Medicago, is a name given to different plants belonging to the Papilionaceous division of the Leguminous order. Black medick is *Medicago Lupulina*; purple medick is *M. sativa*, or lucerne; yellow medick is *M. falcata*. They are all agricultural plants, and of considerable value, but lucerne is the only one generally cultivated. [LUCERNE.] Black medick, also called black nonsuch, is sometimes sown by farmers in dry gravelly soil as the commencement of a pasturage; unless sheep-fed, it lives only for a couple of years, but during that time it affords a crop, and when it dies off, the perennial grasses sown with it cover the land and take its place; but if closely fed by sheep or other animals, it becomes a true perennial, and forms a valuable part of the herbage. Its name is derived, not from the colour of the flowers, for they are yellow, but from that of the pods, which are curved, black, and clustered together at the ends of the branches. That it should be supposed to be the same as hop-trefoil would have scarcely been credible, did we not possess evidence of the fact in one of the best of our English works on agriculture; this latter plant resembles it in the leaves

and flowers; but the latter, when the pods are ripe, cover them over in such a way as to produce the appearance of a head of hop-flowers. Yellow medick is only grown in very poor soils in some parts of Europe; in England it is not an agricultural plant, but is found wild on the tops of old walls and on antient ruins, which it clothes with a green herbage, and thus evinces its fitness for the most sterile places, where there is room for its long roots to extend themselves. Tree medick (*Medicago arborea*) is a large bush in the south of Italy, and was doubtless the plant called *Cytisus* by the Romans.

MEDINA. [ARABIA.]

MEDITERRANEAN (or *Midland-Sea*), the name of the sea between the Straits of Gibraltar to the west and the Dardanelles and Syria to the east. This sea was antiently called The Sea, or the Great Sea, by the Jews. The Greeks do not seem to have had any general name for the Mediterranean: Herodotus calls it 'this sea' (i. 185); and Strabo calls it 'the sea within the columns,' that is, within the Straits of Gibraltar (121, 491, Casaub.). Mela calls the whole sea by the name 'our sea' (*nostrum mare*), and observes that different parts have their several names. Pliny appears to have no general name for it. The term Mediterranean is not applied to this sea by any classical Latin writer. It was called *bahr-roum*, or the sea of Rome, by the Arabs.

The Mediterranean is comprised between the parallels of 30° 15' and 45° 50', and the meridians of 5° 30' W. and 36° 10' E. The distance from Gibraltar to the farthest shore of Syria is 2000 miles, and the narrowest part, between Sicily and Africa, is 79 miles across. The Mediterranean, including the islands, occupies an area of 734,000 square miles. The surface of country of which it receives the drainage is very difficult to estimate, but may be assumed to exceed this quantity. On the shores of this sea have been transacted the most important events in the history of mankind, and its character seems to mark it as the theatre best adapted to the complete and rapid civilization of the race. From the great diversity of soil and productions, under a varied and favourable climate, the colonists, from whatever points they first proceeded, would soon acquire those different habits under which their several energies and capabilities would be developed. The comparative shortness of the distances of the several places, by rendering navigation easy and pleasant in small and imperfect vessels, would, by facilitating intercourse from an early period, tend to diffuse and to promote civilization; while commerce, by bringing together men of different habits, manners, and languages, and thus circulating practical information, would supply the materials for the perfection of the arts and sciences.

As a notice even of a cursory kind, of countries and cities whose history is connected with almost every history in the world, would greatly exceed our limits, we shall confine ourselves almost entirely to those points which concern our subject as a *sea*, referring the reader for all specific local information to the particular names. We shall therefore take a short view of the shores, beginning at Syria and proceeding along Asia Minor to Gibraltar, and return along the coasts of Africa to Egypt, noticing some remarkable historical points, the commerce, winds, currents, and the saltiness of the water, and introducing slight references to the navigation, antient and modern, and the principal naval actions.

The shores of Syria, the general name of the country between Anatolia and Arabia, are mountainous between Tripoli and Tyre, but present in many places a large extent of low and flat coast. The climate is excessively hot in summer, and the winter often severe. The chief ports are Alexandretta, Beyrout, and Tripoli. The trade is carried on in small coasting vessels, but under the oppressive and ignorant government of the Turkish pashas it is very small. Tyre, and Sidon, afterwards still more famous, are reduced to fishing villages. Though the country was antiently inhabited above Mount Carmel by the Phœnicians, but few antient monuments have been found bearing inscriptions.

The coast of Anatolia, the west portion of Asia Minor, is mountainous, rising in some parts very near the sea to 7000 and 8000 feet. It is now a Turkish province. About 20 leagues from the nearest coast of Syria is the island of Cyprus, where the greatest number of Phœnician inscriptions have been found, though none of a date prior to three centuries before Christ. The island of Candia, the name

given by the Venetians to the antient Crete, is highly fertile, productive, and beautiful, but has little trade. The city of Candia stands in the port of the same name; Suda is a fine port. The island of Rhodes, celebrated for the first code of maritime laws, for its schools in the time of the Romans, and in the wars of the Knights of Jerusalem against the Turks, is situated off the south-west corner of Asia Minor, and is now in the hands of the Turks. It produces wine, fruit, and pine-timber.

The numerous islands in the sea called the *Ægean Sea*, between Greece and Asia Minor, forming the Grecian Archipelago, are in general verdant and picturesque, and afford delightful sailing in summer, but they are subject to very heavy squalls. The sides of the islands being steep, and the water very deep, there are in general no anchorages but in particular places. Delos, celebrated for its temple and oracle, was long an emporium of commerce, and was at one time noted for its trade in slaves. It declined in the wars of Mithridates. Scio, a high and beautiful island, covered with the gardens of the Greek merchants, of whom it was the favourite resort, was devastated by the Turks in 1822. Milo is the residence of the pilots of the Archipelago. The Archipelago and its coasts contain many high mountains, as Athos, 6774 feet high, and many others. Smyrna, a place of high antiquity, is the great commercial entrepôt of this part of the world. The chief exports are silk, drugs, and fruits, for which ships carry manufactured goods, sugar, corn, &c. Tenedos, opposite the site of Troy, retains its antient name.

On the opposite side of this sea is Salonica, a large city of 70,000 inhabitants, at the head of a bay. The anchorage is good and the trade considerable, but there is no harbour. The islands Spezzia, Hydra, and Poros, which are near the coast of the Morea, have become distinguished of late years for maritime enterprise.

The coast of the Morea, the antient Peloponnesus, is mountainous, some of the summits exceeding 6000 feet. The country is verdant and of an agreeable aspect, but not well wooded; the productions are numerous, but the trade small. It was given up by the Turks in 1830, to form a part of the new kingdom of Greece. Corinth, at the head of an arm of the sea, and on the isthmus which joins Livadia to the Morea, formerly renowned as one of the most splendid and luxurious of cities, is now a small town exhibiting a few remains of its antient architecture. Athens, beyond the isthmus, is the most populous town of Greece, and has been increasing in importance since the commencement of the reign of Otho, the first king of Modern Greece. It is not a place of much trade.

The coast of Albania, including the antient Illyricum, is more mountainous and rugged: the natives are barbarous, and more athletic than those to the southward. It is now part of the kingdom of Greece; it has but little trade. The known harbours are Antivari, Duleigno, Durazzo, Valona, Parga, and Prevesa. Off this coast and the Morea lie the Ionian Islands. The principal one, Corfu, the antient Corcyra, is the seat of government, which is carried on in the name of the Republic of the Seven Islands, and which is placed under the protection of Great Britain by the treaty of Vienna, 1814. Corfu is picturesque, fertile, and wooded. Cefalonia has a more dreary aspect: it contains a mountain 5380 feet high, which is a conspicuous seamark. Inside Cefalonia is Ithaca, now called Teaki, the native place of Ulysses. The fertile island of Zante, famous for its currants, is to the southward. Proceeding to the northward we enter the Adriatic, the entrance of which is 40 miles broad. The shores of Dalmatia and Istria afford numerous fine harbours, and are covered towards the interior with extensive forests of timber, much of which is fine oak. In Dalmatia is Ragusa, formerly a republic, and a neutral port, and whose flag, prior to the French revolution, was known even to our own shores. Above Ragusa the eastern shores are studded with islands affording good anchorage.

The Greeks, especially the Hydriotes, are active sailors. They employ small vessels, half decked, which both sail and pull, but they seldom venture to sea except in fine weather or with a fair wind. The trade to the Black Sea is chiefly carried on in Greek bottoms.

Trieste, the chief port of Austria, is a large and handsome city, and a place of great trade. It exports wool, tobacco, and the produce of the mines of Hungary. It is a free port.

Venice, founded in the fifth century upon numerous small low islands at the mouth of the Po, celebrated as the entre-

pôt of the commerce between Europe and the Levant, which was at its maximum about the fourteenth century, is still a place of considerable trade, though its wealth and commerce have declined. The chief exports are corn, timber, silk, glass, &c. It has very fine and extensive fisheries. Off Malamocco, the port of Venice, is a bar, across which line-of-battle ships built there have been conveyed in a kind of floating-dock called a camel. During the melting of the snows in spring the freshes of the Po render the waters nearly fresh or brackish to a considerable distance at the head of the Adriatic. This sea is subject to hard northerly gales, called *boras*, especially in winter, which last three days, giving warning of their approach. These winds are very dangerous on the Italian or western shore to leeward. The coasting trade of the Adriatic is chiefly carried on in Austrian vessels and those of the Papal States. The vessels employed are mostly trabaculos, a kind of lugger, and seltces, small vessels of one mast. The chief ports of the coast of Italy which bounds the west side of the Adriatic are Ancona and Brindisi. Ravenna, formerly celebrated as a port, is now five miles inland.

The kingdom of Naples, which forms the south part of Italy, is remarkably fertile, and abounds in beautiful scenery. Its chief exports are olive-oil, silk, and wine. Naples, the capital, would become a place of great trade, but for the system of duties and commercial restrictions. The bay of Naples, with Vesuvius rising to the height of 3880 feet, the city along the shore, the clear Italian sky reflected in the expanse of water, the picturesque islands, and that brilliancy of general effect which is due to the increase of light caused by an approach of some degrees towards the equator, is one of those places which our tourists are fond of describing; but to the eye familiar with the gorgeous magnificence of the tropics, the spectacle is one of lesser dignity. The island of Sicily is one of the most fertile in the world, but under the joint effects of demoralization, bad laws, and the indolence of the government, its resources are not developed. Among the chief sources of commerce is the tunny fishery. These fish enter the Mediterranean in the spring, keeping by the European shore, and leave it again at the close of the year by the coast of Africa. They are caught in nets so contrived that the fish are driven into small compartments, where they are struck and killed. The sword-fish is pursued and struck with a spear having a line fast to the head, with which the fish is played till it is wearied out, in the manner described by Strabo (i. 24, Casaub.). Anchovies are taken along the shores of Sicily, and the *murex purpura* is found. Messina is the great commercial city and port, on the site of the antient Zancle. Scylla is considered in these days as an ordinary rock, but Charybdis is a vortex which might, on occasions, prove dangerous to a small vessel. The chief danger of the Faro is now considered to be merely the baffling winds in a current running from two to five miles an hour, in water too deep for anchoring, and subject to sudden squalls. Messina is famous for the optical illusion called *fata morgana*; and on the coasts a sudden rising and subsidence of the water is experienced, which is called *marobia*. There are no harbours on the south coast, which is low. The spacious harbour of Syracuse on the east coast is often used as a refuge in gales of wind. In the river, the Anapus, the papyrus grows abundantly. The seamen of Sicily are hardy and courageous. Mount *Ætna*, 10,880 feet high, is a conspicuous object in these seas. Among the Lipari or *Æolian* Islands is the constantly burning mountain of Stromboli, which rises like a steep cone from the sea, and is a very interesting object at night. Ustica produces the best vegetable soda.

The principal port on the west coast, and the chief commercial city of Italy, is Leghorn, which is a free port, and one of the principal depôts for wheat from the Black Sea. The principal exports are silk, oil, Carrara marble, alabaster, straw for hats, and wine. The coasting trade is carried on in small Italian vessels. Genoa, once the capital of a republic, but now a Sardinian province, is celebrated for the number and beauty of its marble edifices. The harbour is artificial. The port is free, and the commerce increasing. The chief productions are olive-oil, rice, velvet, &c. The sailors are said to be among the hardiest of the Mediterranean.

The sea to the south-west of Italy was antiently named from the Tyrrhenians, who are among those nations who once possessed the maritime power of the Mediterranean.

The chief port on the south coast of France is Marseille, at the mouth of the Rhône, said to have been founded by a colony of Phœnicians, who, from the great trading facilities of the place, extended their possessions along the shores on both sides. Amongst these are Frejus, where Bonaparte embarked for Elba in 1814; and Cannes, where he landed from Elba in 1815. The Marseillois have been renowned as navigators. The principal exports are silk and wines; there is a great and increasing trade; and from 5000 to 6000 ships arrived in 1831. In the freshes of the Rhône the fresh water may be skimmed far out at sea. Lord Exmouth's fleet watered in this manner in the late war.

Toulon is the great naval arsenal of France. The Gulf of Lions, like all the gulfs on the north shores of the Mediterranean, is subject to violent gales from the northward, which sometimes last three days.

The islands of Sardinia and Corsica, lying north and south, extend over 80 leagues of the sea between Genoa and Tunis. The climate of Sardinia is mild, and the soil fertile. It exports corn, salted provisions, and fruit. The natives of the interior are savage. The Sardinians have few vessels of their own, the trade, even to the fisheries, being carried on by foreigners, principally Genoese. The shipping is chiefly French from Marseille. Corsica is mountainous, rising in some parts upwards of 8000 feet: it produces nearly the same articles as Sardinia, together with marbles and precious stones. Ajaccio, situated on the bay of the same name, is remarkable as the birthplace of Bonaparte. The small island of Malta, composed chiefly of calcareous sandstone, is, from its situation in the narrow sea between Sicily and Africa, and its excellent harbour, the great naval station of the Mediterranean, and second in importance to Gibraltar. The island is productive, and the population dense. Malta was ceded to the English in 1814. The Maltese are active sailors and expert divers; their vessels are small and open.

The east coast of Spain presents numerous harbours, and a highly fertile but not well wooded coast. The chief products are wine and olives and wool. The coast is particularly adapted to navigation by steam-vessels; but the disturbed state of the country, and the commercial restrictions, which do not allow foreign steam-vessels to ply, keep the trade in a very low state. The chief ports are Valencia, which is a very handsome city; Cartagena, which is one of the finest harbours in the world; Barcelona, not adapted to large ships; Alicant, and Malaga.

The Balearic Islands, Majorca, Minorca, with Iviza, one of the Pityusæ, now under the Spanish government, produce wine, corn, fruit, and some manufactures. The chief harbours are Palma and Port Mahon.

Gibraltar, standing at the foot of a rocky mountain, 1430 feet high, is a place of extraordinary strength. From its situation, and the narrowness of the straits dividing Spain from Africa, which are only eleven miles across, Gibraltar is the key of the Mediterranean, and has been the object of violent contests, the last of which terminated in 1783, leaving it in the possession of the British. It is a free port, but not a place of very great trade, and smuggling is extensively carried on. A constant current sets through the Straits of Gibraltar from the Atlantic at the rate of two or three miles an hour, and is felt as far as Cabo de Gata in Spain, 150 miles distant. Dr. Halley supposed this current required to supply the loss by evaporation, considering that the rivers which flow into this sea were not sufficient for the purpose. The writers of the 'Encyclopédie Methodique,' on the other hand, maintained that the waters carried off by evaporation, and returned again in the form of rain, would be precisely the same for the sea outside and inside the straits; and that the numerous rivers of the Mediterranean, by bringing down the waters of distant mountainous regions, would cause a supply in excess, which would require an outward current to carry it off. It had been taken for granted that the water of the Mediterranean must be saltier than that of the ocean, in consequence of the continual supply of this current, and it had been stated to be so in the proportion of 41 to 38. Dr. Marcet however found no difference. The saltiness furnishes the solution of the difficulty, and Mr. Tennant suggested that a comparison of the density at great depths would decide the fact of a contrary or outward current below, since, if the density or increase of saltness increased with the depth, it would naturally follow that a much slower current below would be sufficient to carry off the excess of salt left by evaporation. Capt. Smyth, at the suggestion of Dr. Wollaston, obtained water

from the depth of 400 or 500 fathoms, and at 450 and 680 miles from the straits, in which Dr. Marcet detected no increase of salt; but in the water drawn from 670 fathoms depth, at only 50 miles from the strait, he found four times the usual quantity of saline matter; from which it would appear that a current below of only three-quarters of a mile an hour would prevent any increase in the saltiness of the sea. It may be worth while to mention also that a story is told of a ship which sunk at Ceuta, opposite Gibraltar, having reappeared two miles farther to the westward. (*Phil. Trans.*, 1819, 1822, 1829.)

Tangier is a seaport of Marocco. Ceuta, opposite Gibraltar, is a fortress of great strength. The African shore from this place to Tripoli is hilly, and in some places sandy and sterile; but the country in the interior is highly fertile, though without woods. Algiers, the capital of a kingdom or state, is a place of great strength.

Tunis, the most populous city of Africa after Cairo, stands at the bottom of an extensive bay, from which it is separated by a shallow lake of intense saltiness, from the continued evaporation under a hot sun, and on which are seen great numbers of flamingoes of a brilliant red plumage. The chief trade is with Marseille, to which the inhabitants export corn, the product of these fertile countries now, as it was in the days of antient Carthage. The ruins of Carthage, east of Tunis, and distant 10 miles, with the cisterns, where the ground is strewn with small thin pieces of verd antique and red porphyry, are not the remains of the antient city, but of that which was built afterwards by the Romans.

It is remarkable that on the low shelving shores of parts of these coasts the strong northerly winds do not blow home, and that accordingly a ship may bear up on a lee shore and anchor in smooth water.

Tripoli is the capital of the state of the same name.

Proceeding towards Barca, the antient Ptolemais, we pass the Gulf of Sydra, or Greater Syrtis, an object of so much dread to the antient seamen on account of marshes and sea-monsters. Capt. Smyth, who examined this coast, found that these terrors were poetical exaggerations of the difficulties of navigating a low and dangerous bight. Passing the desert shores of Libya, we arrive at Alexandria, founded on a sandy neck of land by Alexander the Great, whose sagacity pointed out the situation as eminently adapted to commerce.

Alexandria, which was one of the greatest commercial cities that ever existed, began to decline with the invasion of Egypt by the Saracens. Under these warlike people the maritime trade of the East passed to the shores of Syria, and Alexandria further declined as Cairo flourished. The trade however is still considerable: the chief exports are cotton, flax, drugs, spices, &c. The ports of Cairo, on the low and fertile shores of the delta at the mouth of the Nile, are Rosetta and Damietta. Fresh water may be skimmed two or three miles outside the Damietta mouth.

The navigation of the Mediterranean must no doubt be of very early date. The story of Minos destroying pirates (*Thucyd.*, i. 4) takes for granted the fact, that there must have been merchant vessels carrying something worth stealing from the earliest recorded period. If with Strabo we take for granted the accuracy of Homer's descriptions, it by no means follows that the Greeks knew everything that could have been known to every other nation at that time; and the stories told of the jealousy with which the Phœnicians and Carthaginians guarded their discoveries, prove at least that geographical knowledge was not common property; and with regard to these very nations, the knowledge which the Greeks could have had of them, among other barbarians, must have been inferior to that which we possess in the minute accuracy of the Scriptures alone. The story of Utica having been established 130 years before Carthage, proves a regular communication between this place and Syria at a distance of upwards of 1200 miles; and we may conclude that occasional voyages of these enterprising people had already extended the bounds of knowledge far beyond these limits.

If the precise time of the discovery of places lying, as it were, in the thoroughfare of this sea, is so uncertain, the histories of the places in the deep bays of the northern shores must be still more obscure: we shall therefore give at once a slight sketch of the geography of this sea from Strabo, who wrote in the first century.

The stadium adopted by Strabo was that of Eratosthenes, 700 stadia making 1° of latitude or of longitude on the

equator, or 60 nautical miles; hence a stadium is 0.0857 of a nautical mile, this last being about 6082 feet.

The Mediterranean was divided into three basins: the first comprised the sea between the Columns of Hercules and Sicily; the second, between Sicily and Rhodes; and the third, between Rhodes and the shores of Syria.

Strabo supposed that the parallel of latitude of 36½° passed through the Sacred Promontory (Cape St. Vincent), between the Pillars of Hercules (or Gibraltar and Ceuta), dividing this part of the Mediterranean in the middle of its breadth, which was believed by navigators to be 5000 stadia, or 429 nautical miles, from the gulf of Lions to the shore of Africa, but which measures only 330. The sea here however lies altogether to the north of this parallel; and hence, as the configuration of the European shores seems to have been tolerably good, the coast of Africa must have been proportionally distorted. This parallel was carried through the straits of Sicily, Rhodes, and the gulf of Issus, now the gulf of Scanderoon.

In consequence of the above supposition, he placed Marseille to the southward instead of the northward of Byzantium. He supposed Sardinia and Corsica to lie north-west and south-east instead of north and south, and made the distance of Sardinia from the coast of Africa 2400 stadia, or 205 miles, instead of 100, which is the true distance. From the Columns of Hercules to the straits of Sicily he considers to be 12,000 stadia, or 1028 miles: it is only about 800.

From Cape Passaro (Pachynum) to the west extreme of Crete he considered 4500 stadia, or 386 miles; it measures 400: and he supposed the length of Crete 2000 stadia, or 171 miles, the true length being 140 miles. He supposed that a line drawn through Byzantium, the middle of the Propontis, the Hellespont, and along the capes of the coast of Asia Minor, would coincide with the meridian: this error placed Byzantium too far to the north, and not far enough to the east. From Alexandria to the east end of Crete he considered 3000 stadia, or 257 miles: it measures about 290. From Alexandria to Rhodes he made 3600 stadia, or 308 miles: it measures 320. He supposed the head of the Greater Syrtis to be 1000 stadia, or 86 miles, to the south of Alexandria: it is about 60. From Cape Acamas (the west point of Cyprus) to Cape Khelidonia, he made 1900 stadia, or 163 miles; it measures 120 and from Cape Pedalium (Cape Greco) to Berytus (Beirut), he made 1500 stadia, or 129 miles; it measures 90. From Rhodes to Issus he considered 5000 stadia, or 429 miles: it measures 400.

Many of the latitudes given by Strabo are very near, that is, within 10'; those of Marseille and Byzantium excepted, the former being 3° 43' too little, and the latter 2° 16' too much. The longitudes, which were all at that time referred to Cape Sacrum as the first meridian, and the extreme west point, as was believed, of the known world, are without exception too small; that of Carthage, the nearest to the truth, being 1° 9', and Alexandria, the most erroneous, 6° 40', too small.

Fruit is an important article in our Mediterranean trade: fast-sailing vessels are therefore employed to carry it, and a premium is paid to the first vessel arriving in the port of London after a certain period from the commencement of the season. Formerly all the British trade to the Levant was carried on by the Turkey Company. This was an open Company, and was abolished in the reign of Geo. IV.

This sea is navigated by vessels of no great size. There is a form of rig peculiar to the larger vessels, called *polacca*, which has originated in the suddenness and frequency of squalls, which often require the sail to be instantly taken in: for this purpose the masts are made in one piece, and the topsails, on being lowered, can slide down without interruption. The Mediterranean, being studded with places of refuge, and in which gales, though frequent and violent, never last so long as to wear the ship or the spirits of the men, and in which, besides, vessels have from the earliest times to the present ceased to navigate in the winter months, may indeed be favourable to training men to a certain degree of expertness in managing boats, but could never originate that seamanship on the grand scale which the long and boisterous sea-voyages, the rugged and dangerous coasts, and long winter nights, force upon the hardier sailors of the northern regions.

The winds have been remarked as peculiarly variable in the Mediterranean, and three or four vessels have often been seen carrying different winds at the same time. The

scirocco, or south-east wind, has always been noted throughout the Mediterranean for its depressing effects upon the animal system, and for a prejudicial influence still more surprising in other ways, as upon paint newly laid on, which does not dry afterwards. It is usually accompanied with a gloomy sky and haze. In winter its effects are but slightly perceived. Water-spouts are very common, and in the month of September the writer of this article saw sixteen together at one time.

The depth of the Mediterranean is without doubt very great, the sea being in most places unfathomable; and, unlike many other great expanses of water (as the Yellow Sea, the Baltic, and the English Channel), soundings are comparatively of limited utility.

The Mediterranean, though poetically termed a 'tideless sea,' is not strictly so; since in its latitudinal extent between Venice and the Lesser Syrtis it experiences a rise and fall of from five to seven feet. Tides are also felt, but somewhat irregularly, on the sides of the Gibraltar current, in the gulf of Corinth, and in the Faro of Messina; and there is a curious reciprocal motion in the waters in the channel of the Euripus, between Greece and Negropont. Strong currents occur, especially near Venice and the Faro of Messina. The Archipelago currents are noticed in the articles ARCHIPELAGO and EUBŒA. A westerly current sets along the coast of Karamania. It has been stated that an easterly current prevails constantly along the coasts of Africa and Egypt, but this, we believe, has not been substantiated.

The Mediterranean has been the scene of some very important naval actions. The first sea-fight on record was that between the Ionians and their own colony Coreyra, 644 B.C. The first engagement by sea which has been described was that between the Persians, in the reign of Darius, and the confederate Asiatic Greeks, before Miletus, 493 B.C. Thirteen years after this was the famous battle of Salamis, in which the fleet of Xerxes was destroyed. Numerous sea-fights took place between the Greeks and Persians, and amongst the Greeks themselves, and also between the Romans and Carthaginians. Among the latter was the action in which the Carthaginians were beat by the Romans under Duillius, 260 B.C., and which was the first action of the Romans at sea. The most curious circumstance recorded, namely, that the Romans were entirely unpractised in sea affairs, may have been a very good addition to their story; but it is a matter which we receive with some reservation, since, as every one knows, a mere landsman cannot even stand up in a boat on the sea without holding on. To this list may be added the battle of Actium, 30 B.C., in which Augustus triumphed over Antony and Cleopatra; that of 1203, in which the Latins, coming by sea, took Constantinople; the battle of Lepanto, in 1571, in which Cervantes fought; the battle of Sir George Byng, in the Faro of Messina, in 1718; the drawn battle of Admiral Byng, off Mahon, in 1756; the battle of the Nile, in 1798, in which Nelson cut off the communication between France and the expedition under Bonaparte, and destroyed the French naval power in the Mediterranean; the passage up the Dardanelles, by Sir T. Duckworth, in 1808, to force the Turks to agree to a peace with Russia, which object he failed to effect, though he destroyed part of their fleet. In 1816 Lord Exmouth, with the combined Dutch and English fleets, bombarded Algiers, and forced the dey to liberate the Christian prisoners. The last action of importance was that in the bay of Navarino, in which the combined English, French, and Russian squadrons destroyed the Turkish and Egyptian fleets, which was followed by the emancipation of Greece and the invasion of Turkey by the Russians.

Though the several parts of the Mediterranean must long have been intimately known to those frequenting particular places, yet a general and accurate knowledge of its shores is the result of the improved navigation of our own times. In 1783 Tosiño, the Spanish hydrographer, made a survey of the coasts of Spain and the Balearic Islands, in which he employed chronometers. In 1802 Galiano, captain of a Spanish frigate, obtained several chronometric differences between important stations, as Naples, the Levant, Alexandria, the Bosphorus, and the coast of Africa. In 1811 Captain Beaufort surveyed with great accuracy the coast of Karamania in Asia Minor; his further proceedings were stopped by his being dangerously wounded. About three years afterwards Captain Smyth commenced, on his own responsibility, in a Sicilian gunboat, his extensive and valu-

able surveys of great part of the shores both of Europe and Africa, which he completed in the Adventure in 1824, and which have appeared in his chart of the Mediterranean. In 1816 M. Hell, with French officers of engineers, made a detailed survey of Corsica; and M. Gauttier extended a series of triangles over the Archipelago. He also determined by chronometers many positions on the Black Sea. A trigonometrical survey of the Morea was made in 1829-31 by the French under General Pelet, and the west coast of Asia Minor has been completed by Lieutenants Graves and Brock, of the royal navy, who are employed in completing the hydrography of the Archipelago and the remaining coasts. Some points of the coast of Syria were determined by M. Gauttier, and plans of particular ports have been furnished by our own officers, but a regular survey of this coast does not exist.

MEDLEPAD. [ANGERMANNLAND.]

MEDOC. [GIRONDE.]

MEDULLA OBLONGATA. [BRAIN.]

MEDULLA SPINALIS. [NERVOUS SYSTEM.]

MEDULLIN, a name which has been given by Dr. John to the pith of the sunflower, &c.; but it does not appear that its properties have been sufficiently examined to entitle it to be considered as a peculiar principle.

MEDUSA (Zoology), the Linnean name for a genus of simple or free *Acalephans* [ACALEPHÆ, vol. i.], vulgarly known to the British by the name of *Sea-blubbers* or *Sea-nettles*, extremely transparent, difficult to observe in their native element, and still more difficult to preserve, from their gelatinous and easily-decomposed texture. These beautiful but evanescent animals are extremely numerous, swarming on many of our coasts and in our æstuaries, and occurring in almost all latitudes. Péron and Lésueur, Lamarck, Cuvier, Escholtz, and others, have attempted their arrangement with more or less success, and the last-named author divides them into six families, *Rhizostomidæ*, *Medusidæ*, *Geryonidæ*, *Oceanidæ*, *Æquoridæ*, and *Berenicidæ*. M. de Blainville makes them the second class, *Arachnodermata*, of his *Actinozoaria*, and subdivides them into two orders, depending on the absence or presence of a solid piece as a support for the umbrella-like body of the animal. The genera of his order *Cirrhigrada* (the 2nd) are provided with this solid piece [CIRRHIGRADA, vol. vii.]; but those of his first order, *Pulmograda*, have no such support. Under the *Pulmograda* he arranges the numerous sections of the *Medusæ*, and under that title the reader will find a sketch of the most approved systems, and a description and illustration of some of the most remarkable forms, as far as our limits will permit. [PULMOGRADA.]

MEDWAY. [KENT.]

MEERMAN, GERARD, was born at Leyden in 1722, and in 1748 became pensionary of Rotterdam. He spent the greater part of his life in learned research, chiefly relating to law. He died at Aix-la-Chapelle, December 15, 1771. His two great works were, his '*Novus Thesaurus Juris Civilis*,' &c., 7 vols. fol., 1751-53 (to which his son added an eighth volume in 1780), and his '*Origines Typographicæ*,' 2 vols. 4to., Hagæ, 1765. An analysis of this last work was published in '*The Origin of Printing, in two Essays*,' 8vo., Lond., 1774, by Messrs. Bowyer and Nichols; the main object of which was to establish the claim of the town of Haarlem to the invention of printing. (*Biogr. Universelle*, tom. xxviii.)

MEERMAN, JOHN, son of the preceding, was born in 1753. His earliest literary effort was made at the age of ten years, in a translation into Dutch of the '*Mariage Forcé*' of Molière. He commenced his regular studies at Leyden, and afterwards prosecuted them at Leipzig under Ernesti, and at Göttingen under Heyne. At different times in his life he visited nearly every country of Europe. His supplement (an eighth volume) to his father's '*Thesaurus Juris Civilis*' has been already mentioned. The more important of his other works were: '*Specimen Juris Publici de Solutione Vinculi quod olim fuit inter sacrum Romanum Imperium et Fœderati Belgii res publicas*,' 4to., Leyden, 1774; '*A History of William, Count of Holland, King of the Romans*,' in Dutch, 5 vols. 8vo., 1783-97; '*Remarks during a Tour in Great Britain and Ireland*,' 8vo., Hague, 1787; '*An Historical Account of the Prussian, Austrian, and Sicilian Monarchies*,' 4 vols. 8vo., Hague, 1793-4;

'Historical Account of the North and North-East of Europe,' 6 vols. 8vo., Hague, 1804-6; 'A Narrative of the Siege and Conquest of Leyden by John duke of Bavaria, in 1420,' 8vo., Leyden, 1806; all in Dutch. He also published 'Hugonis Grotii Parallelon rerum publicarum, liber tertius de moribus ingenioque populorum, Atheniensium, Romanorum, Batavorum,' with a translation into Dutch, 3 vols. 8vo., 1801-2, and 'Grotii Epistolæ ineditæ,' 8vo., 1806. In 1812 he published, in Dutch and French, a poem entitled 'Montmartre,' and in the same year a 'Discourse on the First Travels of Peter the Great, principally in Holland,' 8vo. His last publication was a translation into Dutch of Klopstock's 'Messiah.'

Under Louis Bonaparte, as king of Holland, he was made Director of the Fine Arts and Minister of Public Instruction, and was entitled to the gratitude of his country for the zeal and success with which he prosecuted his functions. Afterwards, when Holland became united to France, he was made a count of the empire and senator by Napoleon. He died August 15, 1815. The Meerman Library was sold by auction in 1824, and produced no less a sum than 131,000 florins.

(*Biogr. Univ.* tom. xxviii.; *Gent. Mag.* vol. lxxxvi., p. i., p. 639.)

MEERSCHAUM, a magnesian mineral found in the island of Samos and Negropont (Eubœa), in the Archipelago, &c. It is said to be employed as fullers' earth in the Turkish dominions, and in the manufacture of tobacco-pipes.

MEGADERMA. [*CHEIROPTERA*, vol. vii., p. 24.]

MEGADESMA, a name given by Bowdich to a genus of fresh-water *Conchifera* (*Potamophila* of Sowerby, *Gala-thea*, Lam.).

MĒGADHŪTA. [*CALIDASA*.]

ME'GALONYX. [*MEGATHERIIDÆ*.]

MEGALO'PA, Dr. Leach's name for a genus of Macrurous crustaceans (*Macropa* of Latreille).

Megalopa mutica.

a, Magnified; b, internal antenna; c, external antenna; d, natural size.

The external antennæ are setaceous, hardly one-fourth so long as the carapace, and formed of elongated joints; the intermediate ones terminated by two bristle-like appendages, the upper of which is the longest. External *jaux-foot*, with the two first joints compressed, the second the shortest, and notched at the end for the insertion of the others. Anterior feet equal, in form of didactylous pincers, rather short and stout; four last pair rather shorter, less stout, and terminated by a single nail, which is a little curved. *Carapace* short, wide, and a little depressed, terminated in front by a pointed rostrum, which is wide at the base, and sometimes inflected. *Eyes* very large, supported on a very short peduncle. *Abdomen* narrow, extended, linear, composed of seven joints, of which the five intermediate ones are provided with appendages, viz. the four first with false feet, having their external division very large and ciliated, and the fifth, on each side, with a horizontal blade or lamina, which is oval and ciliated, composing, with the last joint, a sort of fin, differing a little from that of the other *Macrura*.

Example, *Megalopa mutica*. This species differs from the others in having the rostrum a little inflected perpendicularly on the carapace and canaliculated in the middle; also in the absence of a recurved spine on the haunches of all the feet. The shell is truncated posteriorly, and has no point like that of *Megalopa armata*. Colour brownish.

Locality.—Found by MM. Audouin and Adolphe Brongniart at the mouth of the Loire.

ME'GALOPHUS. [*MUSCICAPIDÆ*.]

MEGALO'POLIS. [*ARCADIA*.]

MEGALOSA'URUS, the name assigned by Dr. Buck-

land and the Rev. W. Conybeare to an extinct genus of Saurians found in the oolitic slate at Stonesfield near Woodstock and other localities.

Though no entire skeleton has yet been discovered, the number of bones and teeth collected give sufficient data to enable the observer to pronounce upon the general osseous structure, with almost as great a certainty as would be the result of the examination of the bones of the animal in a perfect and connected state.

The femur, or thigh-bone, and tibia, or leg-bone, are nearly three feet in length severally, so that the entire hind-leg must have been nearly two yards long, and the discovery of a metatarsal bone measuring thirteen inches indicates that the foot was of a corresponding length. From these and other remains, including the vertebræ, teeth, &c., the size of this gigantic saurian has been calculated and its habits ascertained.

'The most important part of the *Megalosaurus* yet found,' observes Dr. Buckland, in his 'Bridgewater Treatise,' 'consists of a fragment of the lower jaw, containing many teeth.'

Anterior extremity of right lower jaw of *Megalosaurus*, from Stonesfield, one fourth natural size. a, View of the inside; b, view of the outside. (Buckland.)

'The form of this jaw shows that the head was terminated by a straight and narrow snout, compressed laterally like that of the *Delphinus Gangeticus*.'

Tooth of *Megalosaurus*, two-thirds natural size. The dotted lines indicate the compressed conical cavity, containing pulp, within the root of the growing tooth. a, Transverse section of the same, showing the manner in which the back and sides are enlarged, and rounded in order to give strength, and the front is brought to a strong and thin cutting edge.

The structure of these teeth, another of which is figured in the article *MACHAIRODUS*, leaves no doubt as to the carnivorous habits of this immense extinct lizard; and the internal structure of the cylindrical and other bones shows that it was a terrestrial animal, though it may have occasionally taken to the water in pursuit of prey, such as *Plesiosaurs* and fishes. Its ordinary food is supposed to have been the smaller reptiles, crocodiles, and tortoises, whose remains occur abundantly in the strata where those of *Megalosaurus* abound.

The admirable adaptation of the teeth for carnivorous purpose is beautifully pointed out by Dr. Buckland in the treatise above quoted.

The same author so long ago as the year 1824 figured the fragment of jaw above alluded to and other bones of this saurian, and thus speaks of it in the 1st vol. of the 'Geological Transactions' (2nd series). 'Although the known parts of the skeleton are at present very limited, they are yet sufficient to determine the place of the animal in the zoological system. Whilst the vertebral column and extremities much resemble those of quadrupeds, the teeth show the creature to have been oviparous, and to have belonged to the order of saurians, or lizards. The largest thigh-bone of this animal in the Museum at Oxford is two feet nine inches long, and nearly ten inches in circumference at its central or smallest part. From these dimensions, as compared with the ordinary standard of the lizard family, a length exceeding forty feet and a bulk equal to that of an elephant seven feet high have been assigned by Cuvier to the individual to which this bone belonged; and although we cannot safely attribute exactly the same proportions to recent and extinct species, yet we may with certainty ascribe to it a magnitude very far exceeding that of any living lacerta. Large as are the proportions of this individual, they fall very short of those which we cannot but deduce from a thigh-bone of another of the same species, which has been discovered in the ferruginous sandstone of Tilgate Forest, near Cuckfield in Sussex, and is preserved in the valuable collection of Gideon Mantell, Esq., of Lewes,* together with many other bones belonging to the same species, and of the same size with those from Stonesfield. The femur in question, which has lost its head and lower extremity, measures in its smallest part, at the distance of two feet from its extremity, more than twenty inches in circumference, and therefore, when entire, must have equalled in magnitude the femur of the largest living elephant. To judge from the dimensions of this thigh-bone, its former possessor must have been twice as great as that to which the similar bone in the Oxford Museum belonged; and, if the total length and height of animals were in proportion to the linear dimensions of their extremities, the beast in question would have equalled in height our largest elephants, and in length fallen but little short of the largest whales; but as the longitudinal growth of animals is not in so high a ratio, after making some deduction, we may calculate the length of this reptile from Cuckfield at from sixty to seventy feet.'

In Cuvier's opinion *Megalosaurus* partook of the structure of the crocodile and the monitor. See also Mantell's *Geology of Sussex*; Cuvier, *Ossements Fossiles*; and *Geol. Trans.*, vol. iii. (2nd series).

Besides the localities above mentioned we may notice the occurrence of this animal in the oolite of Normandy; Forest marble, Caen; Jura, near Solothurn? (H. Von Meyer.)

MEGAPODIIDÆ,† Mr. Swainson's name for a family of *Rasores*, consisting of the genus *Menura*, the subgenus *Megapodius*, and the genera *Dicholophus*, *Psophia*, and *Crax*, with the subgenera *Crax*, *Ourax*, *Ortalida*, *Penelope*, and *Lophoceros*. An account of *Dicholophus* will be found under the title *GARIAMA*; and *Psophia* is described under that of *AGAMI*, with the synonym of *Trophia crepitans*, an error for the Linnean name *Psophia crepitans*. For a description of *MÆNURA* see the article. *Megapodius* and the other genera are treated of under the title *CRACIDÆ*, *Lophoceros* being the *Galeated Curassow*, but thus distinguished subgenerically by Mr. Swainson:—'Front of the head with an elevated, pear-shaped, horn-like protuberance. Bill intermediate in shape, between *Crax* and *Ourax*. Cere small. Nostrils basal, oval or round.'

Example, *Crax galeata*.

The genus *Ourax*, as restricted by Mr. Swainson, who gives *Ourax erythrorhynchus* as the type, appears to be the *Ourax Mitu* of Cuvier and others.

MEGARIAN SCHOOL. After the death of Socrates the majority of his disciples retired to Megara (Diog. Laert. ii. 106, iii. 6), where Euclid, one of the oldest of them, resided. [EUCLID.] A few of these disciples remained at Megara with Euclid, who was looked upon as the founder of a school of philosophy which is usually known by the name of Megarian. In this school the Eleatic philosophy

was taught, modified to some extent by the doctrines of Socrates. The Megarian philosophers maintained that the Supreme Good was always the same and unchangeable. They were distinguished in later times by their dialectic subtlety, and by the invention and solution of sophisms; on which account they were called Eristici (ἐριστικοί) and Dialectici (διαλεκτικοί). (Diog. Laert., ii. 106.)

The most celebrated of the successors of Euclid were, Eubulides of Miletus, who opposed certain opinions of Aristotle; Diodorus, surnamed Cronos, who was originally of Iassus in Caria, a pupil of Eubulides, and who lived in Egypt in the time of Ptolemy Soter; and Stilpo, who was originally of Megara, but afterwards resided at the court of Ptolemy Soter.

(Ritter's *History of Antient Philosophy*, b. vii., part i., c. 5; F. Deycks, *De Megaricorum Doctrina*, &c., Bonn, 1827.)

MEGARIMA, the name proposed by Rafinesque for those species of *Terebratula* which are nearly equivalve and smooth, as *T. laevis*, *T. crassa*, &c.

ME'GARIS, one of the political divisions of antient Greece, was separated from Bœotia on the north by the range of Mount Cithæron, and from Attica on the east and north-east by the high land which descends from the north-west boundary of Attica, and terminates on the west side of the bay of Eleusis in two summits, formerly called Kerata, or the Horns, and now Kandili. [ATTICA.] Megaris was divided from the Corinthian territory on the west by the Oneian range of mountains, through which there were only two roads from Corinth into Megaris: one of these, called the Scironian Pass, which is the steep escarpment of the mountains which terminate on the coast of the Saronic gulf, passed by Crommyon (Strabo, p. 391), and along the side of the escarpment was the direct road from Corinth to Athens. This road was made wide enough by the emperor Hadrian for two vehicles abreast (Pausan., i. 40, § 10), but at present it only admits a single vehicle, except in a few places (Thiersch, *De l'Etat Actuel de la Grèce*, ii. 32); yet the road on the whole is in good condition. The other road, following the coast of the Corinthian gulf, crossed the Geranean mountains, which belong to the Oneian range, and led to Pegæ, on the Corinthian gulf, and thence into Bœotia.

The extreme breadth of Megaris, from Pegæ to Nisæa on the Corinthian gulf, is reckoned by Strabo at 120 stadia (p. 334); and the area of the country is calculated by Mr. Clinton, from Arrowsmith's map, at 720 square miles (*Fasti Hell.*, ii., p. 385), which is about the area of the county of Worcester. Megaris is a rugged and mountainous country, and contains only one plain of small extent, in which the capital, Megara, was situated. The rocks are chiefly, if not entirely, calcareous. The country is very deficient in springs.

Megara was built on two hills, on the summit of each of which was a citadel, named respectively Caria and Alca-thous. (Paus., i. 40, § 5; i. 42, § 1.) It was connected with the port of Nisæa by two walls, which were built by the Athenians when they had possession of Megara, B.C. 461-445. (Thucyd., i. 103.) The length of these walls is said by Thucydides (iv. 66) to have been eight stadia, and by Strabo (p. 391) to have been eighteen stadia. Pausanias has described at considerable length the public buildings which existed in Megara in his time; but scarcely any remains of them can now be traced. According to Procopius (*Bell. Vandal.*, i. 1) Megara was 210 stadia from Athens. Dion Chrysostom calls it a day's journey. Dodwell reckons it an eight hours' journey from Athens. (*Class. Tour*, ii. 177.) In front of the harbour of Nisæa was a little island called Minoa, which was occupied by the Athenians during the Peloponnesian war. (Thucyd., iii. 51.) Strabo, in speaking of Minoa, observes, that 'after passing the Scironian rocks we come to the promontory Minoa, which forms the port of Nisæa.' This apparent though not real discrepancy between Thucydides and Strabo has been made to appear greater than it is by translating the Greek word (ἄκρα)* 'peninsula' instead of 'promontory'; which latter term is quite consistent with Minoa being an island, or at least is by no means contradictory to the statement of Thucydides and Pausanias that it was an island. The positions of Minoa and Nisæa seem to be satisfactorily identified by Lieutenant Sprat (*London Geographical Journal*, vol. viii., p. 205).

The port of Pagæ or Pegæ on the Corinthian gulf was

* The reading should be, apparently, δέκα ἢ ὀκτώ, instead of δέκα καὶ ὀκτώ.

* This collection has been purchased by the nation; and is now in the British Museum.

† In Mr. Swainson's work, 'Classification of Birds,' the words are 'Family Megapodine. Greatfoots;' but 'Megapodine' must be an error of the press, the termination of that word being used to indicate a subfamily.

the only other place in Megaris of any importance. Tripodiscus, situated on the road from Pegæ to Megara, is mentioned by Thucydides (iv. 70) and Strabo (p. 394), and is said by Plutarch (*Qu. Gr.*, xvii., p. 387) to have been one of the five hamlets (κῶμαι) into which Megaris was originally divided; the names of which were, Heræa, Piræa, Megara, Cynosuria, Tripodiscus.

According to the traditions preserved by Pausanias (i. 39, § 4, 5), Car, the son of Phoroneus, originally reigned at Megara, and was succeeded, after the lapse of twelve generations, by Lelex, who gave to the people the name of Leleges. Lelex was succeeded by Cleson, and Cleson by Pylas. By the marriage of Pylas with the daughter of Pandion, Megara became annexed to Attica; and there can be no doubt that Megaris in early times belonged to Attica, since it is represented on the best authority that Megaris formed one of the four antient divisions of Attica. On the death of Pandion, Megaris fell to the lot of his son Nisus; but it was wrested from the Athenians during the reign of Codrus, when the Dorians invaded Attica. A Corinthian colony was settled at Megara, and the country was from this time regarded as a Dorian state. It remained for some time subject to Corinth; but it afterwards asserted its independence, but at what time is uncertain. Its wealth and power rapidly increased, as is evident from the numerous colonies which it planted, of which the most important were Selymbria, Chalcedon, and Byzantium, on the Bosphorus and the Propontis, and Hyblæan Megara in Sicily. The navy of Megara was once powerful enough to cope with that of Athens; and it was only after a long and obstinate struggle that the Athenians were enabled to recover the island of Salamis, which had been seized by the Megarians.

The government was originally in the hands of the great Dorian landholders; but they were deprived of their power by Theagenes, who put himself at the head of the popular party, and obtained the sovereignty, about B.C. 620. He adorned the city with several public buildings. (Paus., i. 40, 41.) He married his daughter to Cylon, who was assisted by him in his attempt to usurp the government of Athens. (Thucyd., i. 126.) Theagenes was at length expelled from Megara; and shortly afterwards a most violent struggle arose between the aristocratic and democratic parties, of which a vivid picture is drawn in the poems of Theognis, a native of Megara, who appears to have been born shortly before the death of Solon, and to have lived down to the beginning of the Persian wars.

For some time after the Persian wars Megara appears to have been constantly engaged in war with Corinth; and her enmity to Corinth was the occasion of her forming an alliance with Athens, about B.C. 461. (Thuc., i. 103.) Athenian garrisons were placed in Megara and Pegæ; but six years afterwards the Megarians renounced their alliance with Athens, and put to death the Athenian garrison at Megara (Thuc., i. 114.) In the seventh year of the Peloponnesian war the democratic party formed a plan for surrendering the city to Athens, which was defeated by the arrival of Brasidas with a Lacedæmonian force. We read little more of Megara in Grecian history. In B.C. 357, democracy was again the established constitution. (Diod., xv. 40.) Megara was taken and almost destroyed by Demetrius; it was also taken by the Romans under Metellus (Paus., vii. 15, § 4); it suffered greatly in the invasion of Alaric (Procop., *Bell. Vand.*, i. 1); and its ruin was completed by the Venetians in 1687.

Coin of Megaris.
British Museum. Actual size.

MEGASPIRA, Mr. Lea's name for a pupiform, terrestrial, testaceous mollusk, remarkable for the length of the spire of its shell, which consists of twenty-three close-set, narrow, gradually increasing whorls, which he thus characterises generically:—

Shell clavate; aperture nearly oval, below rounded; margins reflected, above disjoined; columella many-folded, below entire, not effuse.

Animal unknown.

P. C., No. 920.

This genus, which is closely analogous to the genera *Bulinus*, *Pupa*, and *Auricula*, according to Mr. Lea, is founded on a single species, *Megaspira Ruschenbergiana*.

Description. Shell subcylindrical, turrit, thickly striate, brownish, with longitudinal reddish-brown spots, having a solid apex; whorls twenty-three, rather flattened; spire obtuse at the apex; columella with four folds; outer lip reflected.

Megaspira Ruschenbergiana. (Lea.)

MEGA'STHENES lived in the time of Seleucus Nicator, king of Syria, who sent him on an embassy to Ptolemy, the capital of Sandracottus, king of the Prasii. The territories of Sandracottus were on the Ganges and the Jumna. Megasthenes stayed in India several years, and on his return recorded his observations in a work entitled 'Indica.' Of this work, which is unfortunately lost, there are extracts in Strabo, Arrian, and Aelian. Though Strabo has on several occasions expressed an unfavourable opinion of the trustworthiness of the author, it is quite certain that the work contained much valuable information which was then entirely new to the Greeks. Megasthenes gave the first account of Trapobane, or Ceylon.

MEGA'STOMA. [SHRIKES.]

MEGATHERIUM, Megatheroids of Owen, who includes under the family the following genera of extinct *Edentata*, viz. *Megatherium*, *Megalonyx*, *Glossotherium*, *Myodon*, and *Scelidotherium*, all of which have as yet been found in America only.

Megatherium. (Cuvier.)

A gigantic extinct mammiferous quadruped, more nearly allied to the Ant-eaters and Sloths than to the Armadillos. The dental formula cannot be definitely stated, because the number of teeth in the lower jaw is not known. The upper jaw, as Mr. Owen has shown, contains five on each side, and from the analogy of *Scelidotherium* it may be conjectured that *Megatherium* had only four teeth on each side in the lower jaw. In that case the formula would be

$$\text{Incisors } \frac{0}{0}; \text{ canines } \frac{0}{0}; \text{ molars } \frac{5-5}{4-4} = 18.$$

Cuvier pointed out the skull of this animal as very much resembling that of the Sloths, but observed that the rest of the skeleton bore a relationship partly to the Sloths and partly to the Ant-eaters. The Madrid specimen was for a long time the principal, if not the only source of information with regard to the genus, and as Mr. Clift remarks in his paper, to which we shall presently allude more largely,* that magnificent though imperfect skeleton had remained for the last century altogether unique. 'Very few additional specimens,' says that able osteologist, 'appear to have been sent to Europe, and no other cabinet save the solitary one at Madrid possessed (as far as I am able to learn) a single intelligible fragment which could with certainty be assigned to this great unknown.' The zeal and energy of Sir Woodbine Parish have added greatly to the materials for arriving at a just conclusion as to the proper place of this animal in the series; and the history of the *Megatherium* may now be considered to be complete.

According to the description of Don Joseph Garriga,† Spain possessed considerable parts of at least three different skeletons. The first and most complete is that which is preserved in the royal cabinet at Madrid. This was sent over in 1789, by the Marquis of Loreto, viceroy of Buenos Ayres, with a notice stating that it was found on the banks of the river Luxan, west-south-west of Buenos Ayres. In 1795 a second arrived from Lima, and other portions, probably not very considerable, were possessed by Father Fernando Scio, who had received them as a present from a lady who had come from Paraguay. According to MM. Pander and D'Alton, they were unable in 1818 to find any traces of the Lima specimen, or that which had belonged to Fernando Scio.

* Some account of the Remains of the *Megatherium* sent to England from Buenos Ayres, by Woodbine Parish, Junr., Esq., F.G.S., F.R.S., by William Clift, Esq., F.G.S., F.R.S.

† Descripción del esqueleto de un cuadrupedo muy corpulento y raro que se conserva en el Real Gabinete de Historia natural de Madrid. (Madrid, 1796)

The remains collected by Sir Woodbine Parish were found in the river Salado, which runs through the flat alluvial plains (the Pampas) to the south of the city of Buenos Ayres, after a succession of three unusually dry seasons, 'which lowered the waters in an extraordinary degree, and exposed part of the pelvis to view, as it stood upright in the bottom of the river.' This and other parts, having been carried to Buenos Ayres by the country people, were placed at the disposal of Sir Woodbine Parish by Don Hilaro Sosa, the owner of the property on which the bones were found. A further inquiry was instituted by Sir Woodbine Parish, and, on his application, the governor, Don Manuel Rosas, granted assistance, the result of which was the discovery of the remains of two other skeletons on his excellency's properties of Las Averias and Villanueva; the one to the north, the other to the south of the Salado, but

at no great distance from the place where the first had been found. 'An immense shell or case was found with the remains discovered on the properties of Don Manuel, portions of which were brought to this country, but most of the bones associated with the shell crumbled to pieces after exposure to the air,' and the broken portions preserved had not been sufficiently made out, when Mr. Clift published his memoir, to enable that zoologist to describe them satisfactorily; but he gives very accurate figures of a portion of the shell.

The cuts here given will convey to the reader more accurately than words the osseous structure of this enormous animal, which, when full grown, must have been more than fourteen feet long including the tail, and upwards of eight feet in height.

Skeleton of Megatherium. (Clift.)

The simple outline (from Pander and D'Alton) shows the extent of the skeleton at Madrid. The pale tint expresses the extent of corresponding parts sent to England by Sir

Woodbine Parish. The dark tint shows the additional parts, which are deficient in the Madrid skeleton. (*Geol. Trans.*)

Scale of 2 feet.

Skeleton of Megatherium foreshortened, showing a nearly front view of the head and anterior and posterior extremities. (Pander and D'Alton.)

Bones of the pelvis of Megatherium, discovered by Sir Woodbine Parish, now in the Museum of the Royal College of Surgeons, London. The bones of the left hind leg and several of those of the foot are restored nearly to their natural place. (Dr. Buckland, 'Bridgewater Treatise'.)

Ungual phalanx of Megatherium, one-fourth natural size. (Clift.)

Tooth of Megatherium, one-third natural size. (Clift.)

The thigh-bone was twice the thickness of that of the largest elephant; the fore-foot must have measured more than a yard in length, and more than twelve inches in width, and was terminated by an enormous claw, and the width of the upper part of the tail could not have been less than two feet. The following comparative measurements, furnished by Mr. Clift, will be found in Sir Woodbine Parish's interesting forthcoming work,* where a highly characteristic figure of the skeleton, drawn from the original bones, under Mr. Clift's superintendence, shows the parts which are wanting.

	Elephant.		Megatherium.

Circumference of middle of femur . .	1	0	2	2
Length of the os calcis	0	7½	1	5

The whole of the structure of this extinct animal is admirably adapted for digging the earth so as to enable it to obtain the succulent roots, which, in all probability, constituted the principal part of its food. The snout of the animal appears to have terminated in a short pro-

boscis, which must have borne a good deal of resemblance in its proportions to that of the modern Tapirs.

We have seen that an immense shell or case accompanied the remains discovered to the north and the south of the river Salado; and Dr. Buckland was led to suppose, not without considerable apparent ground for the opinion, that this shell was the armour that protected the *Megatherium*.

'The size of the *Megatherium*,' says Dr. Buckland, in his 'Bridgewater Treatise,' 'exceeds that of the existing Edentata, to which it is most nearly allied, in a greater degree than any other fossil animal exceeds its nearest living congeners. With the head and shoulders of a Sloth, it combined in its legs and feet an admixture of the characters of the Ant-Eater, the Armadillo, and the Chlamyphorus; it probably also still further resembled the Armadillo and Chlamyphorus, in being cased with a bony coat of armour. Its haunches were more than five feet wide, and its body twelve feet long and eight feet high;* its feet were a yard in length, and terminated by most gigantic claws: its tail was probably clad in armour, and much larger than the tail of any other beast among extinct or living terrestrial Mammalia. Thus heavily constructed, and ponderously accoutred, it could neither run, nor leap, nor climb, nor burrow under the ground, and in all its movements must have been necessarily slow: but what need of rapid locomotion to an animal whose occupation of digging roots for food was almost stationary? And what need of speed for flight from foes, to a creature whose giant carcass was encased in an impenetrable cuirass, and who, by a single pat of his paw, or lash of his tail, could in an instant have demolished the Cougar or the Crocodile? Secure within the panoply of his bony armour, where was the enemy that would dare encounter this Leviathan of the Patagonia? or in what more powerful creature can we find the cause that has effected the extirpation of his race? His entire frame was an apparatus of colossal mechanism, adapted exactly to the work it had to do: strong and ponderous, in proportion as this work was heavy, and calculated to be the vehicle of life and enjoyment to a gigantic race of quadrupeds, which, though they have ceased to be counted among the living inhabitants of our planet, have, in their fossil bones, left behind them imperishable monuments of the consummate skill with which they were constructed. Each limb and fragment of a limb forming co-ordinate parts of a well adjusted and perfect whole: and through all their deviations from the form and proportion of the limbs of other quadrupeds, affording fresh proofs of the infinitely varied and inexhaustible contrivances of creative wisdom.' Much of this eloquent passage is unassailable: but Professor Owen has demonstrated most clearly, and, we have reason to believe, to the entire satisfaction of Dr. Buckland himself, that the tessellated shell or case found with the Salado remains did not belong to the *Megatherium*, whose tegumentary covering seems to have been not unlike that of the Ant-eaters and Sloths, but to a Dasypodoid or Armadillo-like gigantic extinct animal, to which Mr. Owen has assigned the name of *Glyptodon*, whose hind-foot, like the fore, appears to be expressly modified to form a base to a column destined to support an enormous incumbent weight; whilst in the *Megatherium* the toes were free to be developed into long and compressed claws, such as form the compensating weapons of defence of the hair-clad Sloths and Ant-eaters. Mr. Owen, in his paper read to the Geological Society of London, entitled 'A description of a tooth and part of the skeleton of the *Glyptodon*, a large quadruped of the Edentate order, to which belongs the tessellated bony armour figured by Mr. Clift in his "Memoir on the remains of the *Megatherium* brought to England by Sir Woodbine Parish," showed that the portions of tessellated armour described and figured by Weiss (*Berlin Trans.*, 1827) are identical in structure with those brought to England by Sir Woodbine Parish, and that the bones which were found with the armour in both cases are the same in their characters, and therefore that they belonged to animals specifically identical. He next entered upon the inquiry, Had the *Megatherium* a bony armour? and he concluded, from a comparison of its skeleton with that of the Armadillos, that it had not. In the pelvis of the Armadillo there are twelve sacral vertebræ anchylosed together, and the spines of the vertebræ are greatly developed anteriorly, forming a continuous vertical ridge of bone, bearing immediately the superincumbent

* 'Buenos Ayres and the Provinces of the Rio de la Plata,' Svo., London.

* See above, p. 66.

weight. In the Megathere the sacral vertebræ are only four in number, and are not ankylosed, and the spinous processes are comparatively small, not locked together, as in the Armadillos, but separated by intervals as in the Sloths. In the Armadillos, the weight of the cuirass is transferred from the sacrum to the thigh-bones by two points on each side. One of them, the ischium, is ankylosed to the posterior part of the sacrum, the other point is formed by the conversion of the iliac bone into a stout three-sided beam passing straight from the thigh-joint to abut against the anterior part of the sacrum, where the weight of the shell is greatest, a structure which is wanting in the Megathere. In no species of Armadillo is the ilium expanded, while in the Megathere it is greatly developed, resembling that of the Elephant in size, form, and position; and among the Edentata the nearest approach in this portion of the skeleton is to be found among the Sloths and Ant-eaters. The most striking point however in the structure of the Armadillos, with reference to the support of a bony covering, is the remarkable production of a part of the vertebra from above the anterior articular process on each side, in a straight direction upwards, outwards, and forwards, to nearly the level of the true spinous processes. Now these oblique processes, which are developed only in the loricated Edentata, beautifully correspond in form and use with the tie-bearers in the architecture of a roof, and are entirely wanting in the Megathere, the structure of this part of the vertebral column of that animal corresponding with the character of the vertebræ of the hair-clad Sloths and Ant-eaters. Mr. Owen noticed other supposed adaptations in the skeleton of the Megathere to sustain a bony covering, as the breadth of the ribs, but the ribs of the Sloths and Ant-eaters are broader than those of the Armadillos.

The paper contained a tabular account of the discovery of twelve skeletons of the Megathere, and in no instance did any portion of bony armour occur with or near the bone.* A notice was also given of the remains of a Glyptodon, found in the left bank of the Pedernal before its junction with the Sala, an affluent of the Rio Santo, near Monte Video, and preserved in the museum of that town. From the accounts which have been given of these remains, they appear to have belonged to the same species as that described in the paper. An allusion was also made to some portions of bony armour obtained in the Rio Seco, in the Banda Oriental, and similar in structure to the specimen of the Pedernal. One of the portions was the covering for the tail. It was hollow to its extremity, and presented in its concavity vestiges of caudal vertebræ very distant from each other.

In conclusion, Mr. Owen observes, that having brought together evidence of the remains of five specimens (found in the Rio Seco, Rio Janeiro, Villanueva, Pedernal, and the Banda Oriental) of a large Edentate species undoubtedly covered with armour, and more or less corresponding with the characters of the Glyptodon, and having established the characters of that genus on both dentary and locomotive organs; he trusts at the same time that he has vindicated the opinion of Cuvier with reference to the Megathere, by proving it to be, by its tegumentary covering as well as its osseous system, more nearly allied to the Ant-eaters and Sloths than to the Armadillos. (*Geol. Proc.*, 1839.)

May we venture a suggestion as to the immediate probable cause of the extinction of these and other gigantic quadrupeds whose remains are found in America? The southern parts of that great continent are even now subject to long continued droughts, sometimes lasting for three years in succession, and bringing destruction on the cattle; and, indeed, the discovery of the remains collected by Sir Woodbine Parish was owing to a succession of unusually dry seasons, as we have seen. The upright position of most of these skeletons found in situ, with the ponderous vertebræ and bones of the pelvis in their natural situation, indicates that the animal must have been bogged in adhesive mud sufficiently firm to uphold the ponderous bones after

the decomposition of the soft parts. A long continued drought would naturally have brought these extinct animals from the drained and parched country to the rivers, dwindled, by the continued dry seasons, to a slender stream running between extensive mud banks, in which these gigantic quadrupeds may have been engulfed in their anxious efforts to reach the water.*

Megalonyx. (Jefferson.)

Under this name Mr. Jefferson, formerly President of the United States, described, from some bones found in caverns in the west of Virginia, an extinct mammiferous animal, which he considered to be carnivorous. The bones on which his description was founded were, a small fragment of a femur or a humerus, a complete radius, an ulna complete but broken in two, three claws,† and half a dozen other bones of the foot.

From the materials above mentioned, and on comparison with the analogous bones in the Lion, Mr. Jefferson came to the conclusion that the *Megalonyx* must have been upwards of five feet in height, that it must have weighed nearly nine hundred pounds, that it was the largest of Unguiculated animals, and that it was probably the enemy of the Mastodon of the Ohio, as the Lion is of the Elephant. When once a theory takes possession of the human mind, there is generally no want of materials to confirm it in the imagination of the theorist. Thus Mr. Jefferson appeals to certain figures resembling a Lion mentioned by the most ancient historians of the Anglo-Americans as visible on a rock at the mouth of the Kanhawa, a branch of the Ohio, which must have been traced by the hands of the Indians from their rudeness; and to the accounts of travellers, some of them then living, who had heard during the night frightful roarings which terrified the dogs and the horses; and he asks if they do not prove the existence of some great unknown carnivorous species in the interior of America, and whether this redoubtable animal may not have been the *Megalonyx*?

Dr. Wistar, Professor of Anatomy in the University of Philadelphia, subsequently perceived some analogy between the bones of the fossil foot of Jefferson's animal and similar bones in the foot of the Sloth, without other aid than Daubenton's description.

Cuvier, who saw at once the true analogies of the animal, and was ridiculed for his opinion by Faujas de St. Fond, who mistook the clear-sightedness of that great zoologist for the blindness of one who would constrain nature to bend to the factitious classification of an artificial system, obtained casts of the bones indicated by Jefferson from Mr. Peale of Philadelphia, and was afterwards furnished by M. Palisot de Beauvois with two *morceaux* found in the same cavern where Jefferson's specimens were discovered: fortunately one of these was a tooth. With these additional materials Cuvier completed his labours, and satisfactorily showed that the *Megalonyx* belonged to the *Edentata*.

Mr. Owen, in his description of his genus *Myiodon*, says, 'The greater part of Cuvier's chapter on *Megalonyx* is devoted to the beautiful and justly celebrated reasoning on the ungual phalanx, whereby it is proved to belong not to a gigantic Carnivore of the Lion kind, as Jefferson supposed, but to the less formidable order of Edentate quadrupeds; and Cuvier, in reference to the tooth,—the part on which alone a generic character could have been founded,—merely observes that it resembles at least as much the teeth of one of the great Armadillos as it does those of the Sloths. In the last edition of the "Règne Animal" Cuvier introduces the *Megatherium* and *Megalonyx* between the Sloths and Armadillos, but alludes to no other difference between the two genera than that of size,—"l'autre, le *Megalonyx*, est un peu moindre." Some systematic naturalists, as Desmarest and Fischer, have therefore suppressed the genus, and made the *Megalonyx* a species of *Megatherium*, under the name of *Megatherium Jeffersonii*. The dental characters

* Sir Woodbine Parish has just now (May 29, 1839) kindly communicated to us a letter received by him, giving information of the discovery of an almost entire skeleton of an adult *Megatherium* on the banks of the Rio de la Matanza, with all the vertebræ of the body, all the ribs, all the teeth, the head, and the legs, in short, with the whole of the bones except the tail and one foot. (Close to it was the skeleton of a '*Taton gymnesque*' (Glyptodon probably), with its bony armour complete. There was also found a very small and perfect *Megatherium* which must have been only just born at the epoch of destruction. No mention is made of any traces of bony armour or shell about the *Megatherium*. In the old animal only one foot is wanting. It has been suggested that the so-called young *Megatherium* may possibly be a skeleton of *Scelidotherium*.

* Mr. Darwin states that he was informed by an eye witness, that during the 'gran seco' the cattle in herds of thousands rushed into the Parana, and being exhausted by hunger, they were unable to crawl up the muddy banks, and were drowned. (*Voyages of the Adventure and Beagle between the years 1826 and 1836*, vol. iii., 1839.) Sir Woodbine Parish says, 'In the last great drought, which continued during the summers of 1830, 31, and 32, it was calculated that from a million and a half to two millions of animals died:—the borders of all the lakes and streamlets in the province were long afterwards white with the bones.' (*Buenos Ayres and the Provinces of the Rio de la Plata*, 8vo., 1839.)

† The ungual phalanx of *Megalonyx* is much more compressed than that of *Megatherium*.

of the genus *Megatherium* are laid down by Fischer, as follows:—"Dent. prim. et lan. $\frac{0}{0}$; molares $\frac{4-4}{4-4}$, obducti, tritores, coronide nunc planâ transversim sulcatâ, nunc medio excavatâ marginulis prominulis." That *Megalonyx* had the same number of molares as *Megatherium* (supposing that number in the *Megatherium* to be correctly stated, which it is not) is here assumed from analogy, for neither Jefferson, Wistar, nor Cuvier,—the authorities for *Megalonyx* quoted by Fischer,—possessed other means of knowing the dentition of that animal than were afforded by the fragment of a single tooth.* (Owen, in *Zoology of H. M. S. Beagle*.)

The same author (*loc. cit.*) adds, 'With respect to existing Mammalia, most naturalists of the present day seem to be unanimous as to the convenience at least of founding a generic or subgeneric distinction on well-marked modifications in the form and structure of the teeth, although they may correspond in number and kind, in proof of which it needs only to peruse the pages of a *Systema Mammalium* which relate to the distribution of the Rodent order. According to this mode of viewing the logical abstractions under which species are grouped together, the extinct Edentate Mammal discovered by Jefferson must be referred to a genus distinct from *Megatherium*, and for which the term *Megalonyx* should be retained. This will be sufficiently evident by comparing the descriptions given by Cuvier of one of the teeth of *Megalonyx Jeffersonii*, and by Dr. Harlan of a tooth of his *Megalonyx laqueatus*, with those of the *Megatherium* which have been published by Mr. Cist. The fragment of the molar tooth of the *Megalonyx Jeffersonii*, described and figured in the 'Ossements Fossiles,' seems to have been implanted in the jaw like the teeth of the *Megatherium* by a simple hollow base, similar in form and size to the protruded crown: its structure Cuvier describes as consisting of a central cylinder of bone enveloped in a sheath of enamel. The transverse section of this tooth presents an irregular elliptical form, the external contour being gently and uniformly convex; the internal one undulating, convex in the middle, and slightly concave on each side, arising from the tooth being traversed longitudinally on its inner side by two wide and shallow depressions. The imperfect tooth of the species called by Dr. Harlan *Megalonyx laqueatus*, and of which a cast was presented by that able and industrious naturalist to the Museum of the Royal College of Surgeons, resembles in general form, and especially in the characteristic double longitudinal groove on the inner side, the tooth of the *Megalonyx Jeffersonii*.'

Two claws of the fore-foot, a radius, humerus, scapula, one rib, an os calcis, a metacarpal bone, some vertebrae, a femur, and a tibia of *Megalonyx laqueatus*, which were discovered in Big-bone Cave, Tennessee, United States, are also described by Dr. Harlan,* who, though he does not enter into the question of the generic characters of *Megalonyx*, seems, as Mr. Owen observes, to feel that they do not rest entirely on dental modifications; for Dr. Harlan remarks that 'a minute examination of the tooth and knee-joint renders it not improbable, supposing the last-named character to be peculiar to it, that if the whole frame should hereafter be discovered, it may even claim a generic distinction, in which case either Aulaxodon or Pleurodon would not be an inappropriate name.' Upon this Professor Owen makes the following pertinent observation:—"There can be no doubt, as it appears to me, with respect to a fossil jaw presenting teeth in the same number and of the same general structure as in the *Megatherium*, and with individual modifications of form as well marked as those which distinguish *Megatherium* from *Megalonyx*, that the palæontologist has no other choice than to refer it, either as Fischer has done with *Megalonyx*, to a distinct species of the genus *Megatherium*, or to regard it as a type of a subgenus distinct from both. With reference however to the Pleurodon of Dr. Harlan, after a detailed comparison of the cast of the tooth on which that genus is mainly founded with the descriptions and figures of the tooth of the *Megalonyx Jeffersonii* in the "Ossements Fossiles," they seem to differ in so slight a degree as to warrant only a specific distinction, and this difference even, viewing the various proportions of the teeth in the same jaw of the *Megatherium*, is more satisfactorily established by the characters pointed out by Dr. Harlan, in the form and proportions of the radius, than by those of the tooth itself.'

* 'Medical and Physical Researches,' p. 323, &c.

Among the bones collected by Spix and Martius in the cave of Lassa Grande, near the Arrayal de Torracigos in Brazil, and described by Professor Doellinger,† there were no teeth, and only a few bones of the extremities. The Professor concludes from their shape, the presence of an osseous sheath for the claw, and the form of their articulation, that they doubtless belong to a Megatheroid animal of the size of an Ox. The bones, according to the Professor, are not those of an immature individual, and agree sufficiently with Cuvier's descriptions and figures of the *Megalonyx* to warrant their being referred to that kind of animal.

Glossotherium. (Owen.)

This genus is founded on a fragment of a cranium in Mr. Darwin's collection, discovered in the bed of the same river in Banda Oriental with the skull of the *Totoodon*. The fragment includes the parietes of the left side of the cerebral cavity, the corresponding nervous and vascular foramina, the left occipital condyle, a portion of the left zygomatic process, and, though last, not least, the left articular surface of the lower jaw. No tooth, no locomotive extremity, was present to lend its aid; and yet, upon the slender materials above stated, Professor Owen has been enabled to give generic distinction to the animal to which they belonged, and to fix its place in the animal series satisfactorily.

Professor Owen remarks, that the importance of the articular surface of the lower jaw in the determination of the affinities of a fossil animal has been duly appreciated since the relations of the motions of the lower jaw to the kind of life appointed for each animal were pointed out by Cuvier; but he observes that we should be deceived if we were to establish, in conformity with the generalization laid down by Cuvier, our conclusion, from this surface, of the nature of the food of the extinct species under consideration; for the shape of the glenoid cavity is such as to allow the lower jaw free motion in a horizontal plane from right to left, and forwards or backwards, like the movements of a millstone: 'Nevertheless,' continues Mr. Owen, 'I venture to affirm it to be most probable that the food of *Glossotherium* was derived from the animal and not from the vegetable kingdom, and to predict, that when the bones of the extremities shall be discovered, they will prove the Glossotherium to be not an ungulate but an unguiculate quadruped, with a fore foot endowed with the movements of pronation and supination, and armed with claws, adapted to make a breach in the strong walls of the habitations of those insect societies upon which there is good evidence, in other parts of the present cranial fragment, that the animal, though as large as an ox, was adapted to prey.'

The data on which Professor Owen rests this affirmation are, in the first place, a remarkable cavity situated immediately behind the tympanic bone, of nearly a regular hemispherical form and an inch in diameter. The surface of this cavity does not appear to have been covered with articular cartilage, because it is irregularly pitted with many deep impressions, and Mr. Owen concludes therefore that it served to afford a ligamentous attachment to the styloid element of a large *os hyoides*. In addition to this evidence of the size of the bones of the tongue, there is a more certain indication of the extent of its soft and especially its muscular parts in the magnitude of the foramen for the passage of the lingual or motor nerve, which anterior condyloid foramen is larger than any of those which perforate the cranium, with the exception of the great foramen; it is eight lines in the long diameter, and readily admits the passage of the little finger.

The professor remarks that it is only in the Ant eaters and Pangolins that we find an approximation to these proportions; and that in the Giraffe, the largest of ruminants, and having the longest and most muscular tongue in that order, the foramen for the corresponding nerve is scarcely more than one fourth the size of that of *Glossotherium*. In the other parts of the cranium Mr. Owen finds more decisive evidence of the relationship of this extinct edentate to the genera *Myrmecophaga* and *Manis*.

The question, Had the *Glossotherium* teeth? is answered by the Professor in the affirmative, from the rugged surface of the temporal fossa indicating an extensive temporal muscle; from the well-defined boundary, formed by

† Spix and Martius, 'Reise in Brazil,' band ii., p. 5.

a slightly-elevated bony ridge, extending to near the sagittal suture; the size of the zygomatic portion of the temporal bone, and the remains of the oblique suture by which it was articulated to the malar bone; and he is of opinion that they will probably be found to be molar teeth of a simple structure, as in the *Orycteropus*.

Here is evidence of the existence of an *os malæ*. This bone is wanting in the Pangolins; in the true Ant-eaters it does not reach the zygomatic process of the temporal bone. From this evidence of the completion of the zygomatic arch, the Professor concludes that *Glossotherium* was more nearly allied to the Armadillos and *Orycteropus*; and from the form and loose condition of the tympanic bone, which, through the care and attention of Mr. Darwin, was preserved *in situ*, that the affinity of the animal was closer to *Orycteropus* than to the Armadillos: but the tympanic bone of *Orycteropus* differs from that of *Glossotherium* in forming part of the circumference of an ellipse whose long axis is vertical, and in sending outwards from its anterior part a convex eminence, which terminates in a point directed downwards and forwards: in the distance from the origin of the zygoma to the occipital plane, which is relatively greater in *Glossotherium* than in *Orycteropus*, the former is more similar to *Myrmecophaga* and *Munis*.

The internal surface of the cranial fragment shows that in *Glossotherium*, as in other *Bruta*, the cerebellum must have been almost entirely exposed behind the cerebrum, that the latter was of small relative size, not exceeding that of the Ass; and that it was chiefly remarkable, as in *Orycteropus*, the Ant-eater, and Armadillo, for the great development of the olfactory ganglia.

Such are the leading points on which the establishment of this extinct genus is placed. Our limits do not admit of our following out the interesting details which confirm the view taken by Mr. Owen, and which the reader will find in his 'Fossil Mammalia,' as part of the 'Zoology of the Voyage of Her Majesty's Ship Beagle, under the command of Captain Fitzroy, R N., edited and superintended by Mr. Darwin, and published with the approval of Her Majesty's Treasury;' but we think it advisable, with reference to the succeeding fossil species described by the Professor, and here noticed, to give the concluding paragraph in his paper on *Glossotherium*.

'A question,' says Professor Owen, 'may arise after porusing the preceding evidence, upon which the present fossil is referred to a great Edentate species nearly allied to the *Orycteropus*, whether one or other of the lower jaws, subsequently to be described, and, in like manner, referrible, from their dentition, either to the *Orycteropodoid* or *Dasypodoid* families of *Edentata*, may not have belonged to the same species as does the present mutilated cranium. I can only answer, that those jaws were discovered by Mr. Darwin in a different and very remote locality; that no fragments or teeth referrible to them were found associated with the present fossil; and that, as it would be therefore impossible to determine from the evidence we have now before us which of the two lower jaws should be associated with *Glossotherium*; and as both may, with equal, if not greater probability, belong to a totally distinct genus, it appears to me to be preferable, both in regard to the advancement of our knowledge of these most interesting *Edentata* of an ancient world, as well as for the convenience of their description, to assign to them, for the present, distinct generic appellations.'

Mylodon. (Owen.)

A genus of Edentate Megatherioids, founded on some fossil remains described by Dr. Harlan in his 'Medical and Physical Researches,' and referred by him to *Megalonyx*, and on a mutilated lower jaw and teeth discovered by Mr. Darwin among the many interesting novelties which have been the result of that zealous naturalist's researches in the southern division of America.

The fossil last alluded to was found in a bed of partly consolidated gravel at the base of the cliff called Punta Alta, at Bahia Blanca, in Northern Patagonia, and consists of the lower jaw, with the series of teeth entire on both sides: the extremity of the symphysis, the coronoid and condyloid processes, and the angular process of the left ramus, are wanting.

The teeth are implanted in very deep sockets, and about one sixth only of the last molar projects above the alveolus; but the proportion of the exposed part increases gradually

Lower jaw of Mylodon, one-sixth nat. size. (Owen.)

in the anterior teeth. This and the relative distance of the teeth will be seen in the following figure.

External view of right ramus of lower jaw of Mylodon (profile), one-sixth nat. size.

The implanted part of each tooth is simple, of the same size and form as the projecting crown, and with a large conical cavity at the base, for the persistent pulp, and indicating that their growth, during life, was perpetual.

Teeth of Mylodon, showing the depth of their implantation. The cavity at the base of the tooth is seen in figure a. Two-thirds nat. size. (Owen.)

Professor Owen remarks that these teeth are composed, as in *Bradypus*, *Megatherium*, and *Megalonyx*, of a central pillar of coarse ivory, immediately invested with a thin layer of fine and dense ivory, and the whole surrounded by a thick coating of cement.

The exterior surface of the symphysis of the jaw (which is completely ankylosed) is characterised by two oval mam-milloid processes, situated on each side of the middle line, and about half-way between the anterior and posterior extremes of the symphysis. Nearly four inches behind the anterior extremity of the above process is the large anterior opening of the dental canal, which is five lines in diameter, and situated about one-third of the depth of the ramus of the jaw from the upper margin. The Professor observes that the magnitude of this foramen, which gives passage to the nerve and artery of the lower lip, indicates that this part was of large size; and that the two symphyseal processes, which probably were subservient to the attachment of large retractor muscles, denote that the motions of such

a lip were free and extensive. The angle of the jaw is produced backwards, and ends in an obtuse point, slightly bent upwards; a foramen, one-third less than the anterior one, leads from near the commencement of the dental canal to the outer surface of the jaw, a little below and behind the last molar tooth; and this foramen presents the same size and relative position on both sides of the jaw. Mr. Owen finds no indication of a corresponding foramen, or of symphyseal processes in the figures or descriptions of the lower jaw of the *Megatherium*, nor in that of the Sloths, Ant-eaters, Armadillos, or Manises, which he had examined with a view to this comparison.

Mr. Owen further observes that in the *Megatherium* the inferior contour of the lower jaw is peculiarly remarkable, as Cuvier has observed, for the convex prominence or enlargement which is developed downwards from its middle part; but in the *Myiodon* the corresponding convexity is slight, not exceeding that which may be observed at the corresponding part of the lower jaw of the Ai or the *Orycteropus*; and after entering into further interesting details, the Professor comes to the conclusion that the lower jaw of the *Myiodon* is very different from that of the *Megatherium*; with that of *Megalonyx* he had of course no means of comparing it.

'Among existing *Edentata*,' continues the Professor, 'the *Myiodon*, in the form of the posterior part and angle of the jaw, holds an intermediate place between the Ai and the great Armadillo: in the form of the anchylosed symphysis of the lower jaw it resembles most closely the Unau, or two-toed Sloth; but in the peculiar external configuration of the symphysis, resulting from the manilloid processes above described, the *Myiodon* presents a character which has not hitherto been observed in any other species of *Bruta*, either recent or fossil.'

Two species, *Myiodon Harlani*, founded on the fossil described by Dr. Harlan, and *Myiodon Darwinii*, on that discovered by Mr. Darwin, are recorded by Professor Owen; and he gives the following admeasurements of the lower jaw of the latter species:—

	Inches.	Lines.
Length (as far as complete)	17	6
Extreme width, from the outside of one ramus to that of the other	9	0
Depth of each ramus	4	9
Length of alveolar series	4	8
From first molar to broken end of symphysis	6	0
Breadth of symphysis	3	7
Longitudinal extent of symphysis	4	6
Circumference of narrowest part of each ramus	5	9

He further observes that the teeth and bones of *Myiodon Darwinii*, above described, exhibit all the appearances and conditions of those of a full-grown animal, and that they present a marked difference of size as compared with those of *Myiodon Harlani*, which must have been a much larger animal, for if the lower jaw of the latter species bears the same proportion to its teeth as that of *Myiodon Darwinii* does, it must be about two feet in length. (*Zoology of H. M. S. Beagle*.)

Scelidotherium. (Owen.)

A large extinct edentate mammal, allied to *Megatherium* and *Orycteropus*.

The remains on which this genus is founded include the cranium, which is nearly entire, with the teeth, and part of the *os hyoides*; the seven cervical vertebrae, eight dorsal and five sacral vertebrae, both scapulae, the left humerus, radius and ulna, two carpal bones, and an ungual phalanx; the two femora, the proximal extremities of the left tibia and fibula, and the left astragalus.

These bones were discovered by Mr. Darwin at Punta Alta in Northern Patagonia, and in the same bed of partly consolidated gravel as that wherein the lower jaws of *Toxodon* and *Myiodon* were imbedded. All the parts were discovered in their natural relative position, indicating, as Mr. Darwin observes, that the sublittoral formation in which they had been originally deposited had been but little disturbed. This beach is covered at spring-tides, and many portions of the skeleton were encrusted with *Fusustræ*: small marine shells were lodged within the crevices of the bones.

Sufficient of the cranium remains to indicate that its general form resembled an elongated, slender, subcompressed cone, beginning behind by a flattened vertical base

which expanded slightly to the zygomatic region, and thence contracted gradually in all its dimensions to the anterior extremity.

Remains of skull of *Scelidotherium*. (Owen.) Reduced.

'The Cape Ant-eater (*Orycteropus*)' [AARD-VARK], says Professor Owen, 'of all *Edentata*, most nearly resembles the present fossil in the form of its cranium, and next in this comparison the great Armadillo (*Dasypus Gigas*, Cuv.) may be cited: on the supposition therefore that the correspondence with the above existing Edentals observable in the parts of the fossil cranium which do exist, was carried out through those which are defective, the length of skull of the *Scelidotherium* must have been not less than two feet. The cranium is singularly small and slender in proportion to the rest of the skeleton, especially the bulky pelvis and femur, of which bones the latter has a length of seventeen inches, and a breadth of not less than nine inches: the astragalus again exceeds in bulk that of the largest Hippopotamus or Rhinoceros; yet the condition of the epiphyseal extremities of the long bones proves the present fossils to have belonged to an immature animal. Hence, although the *Scelidotherium*, like most other Edentals, was of low stature, and, like the *Megatherium*, presented a disproportionate development of the hinder parts, it is probable that, bulk for bulk, it equalled, when alive, the largest existing pachyderms not proboscidean. There is no evidence that it possessed a tessellated osseous coat of mail.'

Professor Owen gives a most minute and interesting description of the various parts of the cranium, for which we refer to his memoir, remarking only that the most interesting features in the region of the temporal bone consist in the fine condition of the tympanic bones, and the presence of a semicircular pit, immediately behind the tympanic bone, for the articulation of the styloid element of the hyoid or tongue bone.

'In these points,' observes the Professor, 'we trace a most remarkable correspondence with the *Glossotherium*, and in the separate tympanic bone the same affinity to the *Orycteropus* as has been already noticed in the more bulky extinct Edental. This correspondence naturally leads to a speculation as to the probable generic relationship between the *Glossotherium* and *Scelidotherium*: now it may first be remarked that the styloid articular depression is relatively much larger and much deeper in the *Glossotherium* than in the *Scelidotherium*: in the former its diameter equals, as we have seen, one inch; in the *Scelidotherium* it measures only a third of an inch, the whole cranium being about two-fifths smaller. If we turn next to the anterior condyloid foramina, which in the *Scelidotherium* are double on each side, we obtain from them evidence that the muscular nerve of the tongue could only have been one-third the size of that of the *Glossotherium*. These proofs of the superior relative development of the tongue in the *Glossotherium* indicate a difference of habits, and a modification probably of the structure of the locomotive extremities; and when we associate these deviations from the *Scelidotherium* with the known difference in the position of the occipital plane, which in the *Glossotherium* corresponds with that in the *Myrmecophaga* and *Bradypus*, we shall be justified in continuing to regard them, until evidence to the contrary be obtained, as belonging to distinct genera.'

The bones of the cranium connected with the organ of hearing and an accidental fracture of the right *os petrosum*, demonstrating its usual dense and brittle texture, and at the same time exposing the cochlea with part of its delicate and beautiful lamina spiralis, give Professor Owen occasion to observe that the conservation of parts of the organs of vision in certain fossils has given rise to arguments which prove that the laws of light were the same at remote epochs of the earth's history as now; whilst the structures just

alluded to demonstrate, in like manner, that the laws of acoustics have not changed, and that the extinct giants of a former race of quadrupeds were endowed with the same exquisite mechanism for appreciating the vibrations of sound as their existing congeners enjoy at the present day.

'The brain,' says Mr. Owen, 'being regulated in its development by laws analogous to those which govern the early perfection of the organ of hearing, appears to have been relatively larger in the Scelidotherium than in the Glossotherium: it was certainly relatively longer; the fractured cranium gives us six inches of the antero-posterior diameter of the brain, but the analogy of the Orycteropus would lead to the inference that it extended further into the part which is broken away. The greatest transverse diameter of the cranial cavity is four inches eight lines; their dimensions however are sufficient to show that the brain was of very small relative size in the Scelidotherium; and, both in this respect and in the relative position of its principal masses, the brain of the extinct Edental closely accords with the general character of this organ in the existing species of the same order. We perceive by the obtuse ridge continued obliquely upwards from above the upper edge of the petrous bone, that the cerebellum has been situated wholly behind the cerebrum; we learn also, from the same structure of the enduring parts, that these perishable masses were not divided, as in the Manis, by a bony septum, but by a membranous tentorium, as in the Glossotherium and Armadillos: in the Orycteropus, as has been before remarked, there is a strong, sharp, bony ridge extending into each side of the tentorium. The vertical diameter of the cerebellum and medulla oblongata equals that of the cerebrum, and is two inches three lines: the transverse diameter of the cerebellum was about three inches nine lines; its antero-posterior extent about one inch and a half. The sculpturing of the internal surface of the cranial cavity bespeaks the high vascularity of the soft parts which it contained, and there are evident indications that the upper and lateral surfaces of the brain had been disposed in a few simple parallel longitudinal convolutions. The two anterior condyloid foramina have the same relative position as the single corresponding foramen in the Glossotherium, Orycteropus, and Armadillos; and the inner surface of the skull slopes outwards from these foramina to the inner margin of the occipital condyle.'

The size of the orbit is relatively smaller than in the Orycteropus, and still less than in the Ant-eaters. 'Here however,' observes Mr. Owen, 'we have merely an exemplification of the general law which regulates the relative size of the eye to the body in the Mammalia. The malar bone does not extend so far forwards in front of the orbit as in either the Orycteropus or Armadillo; in the inclination however with which the sides of the face converge forwards from the orbits, the Scelidotherium holds an intermediate place between the Armadillos and Orycteropus.'

The dental formula of Scelidotherium appears to have been:—

$$\text{Incisors } \frac{0}{0}; \text{ Canines } \frac{0}{0}; \text{ Molars } \frac{5-5}{4-4} = 18.$$

Though the teeth of *Myiodon* and *Scelidotherium* have a close analogy to those of existing small Insectivorous Edentals, there is nothing in their structure to militate against the presumption that these extinct genera were fed on succulent plants, such as cabbage-palms, or on farinaceous vegetables, such as large ferns. Their teeth are well adapted to chew vegetable tissues of moderate firmness. (*Zoology of H. M. S. Beagle*.)

One-half nat. size.

Dentition of Scelidotherium.

a, Teeth of upper jaw in situ, seen from above; b, teeth of lower jaw in situ, same view; c, d, teeth, showing the depth of their implantation in the jaw and their structure; e, crown of tooth, seen from above. (Owen.) Reduced.

After the above was written, and indeed while the article was in the press, we received the *Comptes Rendus* (April, 1839), in which appears an extract of a letter from M. Lund to M. Victor Audouin, dated the 5th of November, 1838, giving an account of the discovery by M. Lund of numerous fossil mammals in Brazil. The portion of the country examined by this zealous zoologist is comprised between the rivers Rio das Velhas, one of the confluent of the Rio de S. Francisco, and the Rio Paraopeba. This tract forms an elevated plateau of 2000 feet above the level of the sea, and is traversed in the midst by a mountain-chain only from 300 to 700 feet high. The chain is formed by a secondary limestone (calcaire secondaire) stratified horizontally and having all the characters of the *zechstein* and the *hohlen-kalkstein* of the Germans (*calcaire à cavernes*). It is entirely riddled with caverns and traversed in all directions by fissures, the interior of which is more or less filled with a red earth identical with the red earth which forms the superficial bed of the country. In this basin of the Rio das Velhas, M. Lund has discovered in company with the remains of *Feræ*, *Glires*, *Pachydermata*, *Ruminantia*, *Marsupialia*, *Cheiroptera*, and *Simia*, the following mammiferous fossils, which seem to claim attention here.

'Family of Edentata.

'A *Myrmecophaga* of the size of an ox (*Myrmecophaga gigantea*).

'Family of Effodientia.

'1. Two species of *Dasypus*; one allied to *D. octocinctus*, and the other twice as large as the living species.

'2. *Xenurus*. 3. *Euryodon*, a lost genus of *Tatou*, or Armadillo. 4. *Heterodon**, distinguished from all the living armadillos by the proportion of its teeth. 5. *Chlamydothorium*, a new genus of armadillo, representing on a great scale the genus *Euphractus* of Wagler (the *Encober* of Buffon); two species, one of the size of a tapir, the other larger than a rhinoceros.

'6. *Hoplrophorus*. A very extraordinary genus, whether we consider the massive proportions of the species, their gigantic stature, or the singular combination of different types of organization manifested in them. Their characters nevertheless approach more and more to the family of sloths.

'These singular animals were armed with a cuirass which covered all the upper parts of their body, and was composed of small hexagonal scutcheons, except on the middle of the body, where the scutcheons put on a square form and were arranged in immoveable transverse bands. The bones of the trunk as well as the large bones of the extremities are very similar to those of the Armadillos (*Tatous*) and especially to those of the *Cachicames* [*ARMADILLO*, vol. ii., p. 352]; but the bones of the feet are so abridged and the articular surfaces present such a considerable flattening, that nothing similar is to be seen in any animal skeleton, and one cannot conceive how such feet could serve for digging in the earth (*creuser la terre*): the form of the teeth, too, indicates that these singular animals could only have been nourished with vegetable substances, and we must suppose that they fed after the manner of the great *Pachydermata*. However this may be, the *Hoplrophori*, of which

* This name is preoccupied. See the title.

M. Lund distinguishes two species, present this particularity, that their zygomatic arch is furnished with a descending branch, a character regarded till now as exclusively proper to the Sloths. These two species were each of the size of an ox. Fragments of these skeletons have already been described by MM. Weiss and D'Alton of Berlin.

M. Lund has found fragments belonging to a genus approaching *Hoplophorus*, and to which he assigns the name of *Pachytherium*. Its proportions were still more massive and its stature taller.

Family of Bradypoda.

M. Lund is thus conducted to the family of the Sloths, which, "at the Antediluvian epoch," played in the countries a very important part, whether the number and variety of their forms, or the great size which the species attained, are considered.

The first genus which he notices is *Megalonyx*. It is connected with the Armadillos (Tatous) by the osseous plates which protected a part of its body; but these plates, although of excessive size, far from forming a continuous cuirass as in the Tatous, were separated from each other by great intervals. The *Megalonyx* exhibits the greatest affinity to *Megatherium*, principally in the structure and composition of the feet, but those of the posterior limbs present the same torsion as the feet of *Bradypus tridactylus*, although proceeding from a different cause. In the *Ai* this torsion is produced by the particular mode of the articulation of the leg with the astragalus; in the *Megalonyx*, according to M. Lund, the articulation is effected in the ordinary manner, and it is the carpal surface of this last bone which, by its anomalous conformation, caused the contorsion of all the rest of the foot.

The molars, to the number of five above and four below, are deprived of roots as in the animals of the order *Edentata*; in that they differ from those of *Megatherium*, which are described as having two roots.*

The *Megalonyxes* were provided with a tail, which was excessively strong and probably prehensile, and this, joined to the contorsion of the hind feet and the enormous size of their claws, leads to the belief, says M. Lund, that these animals, notwithstanding the enormous weight of their body, were destined to climb, like their analogues in the present creation.

This genus appears to have been very rich in species. M. Lund already distinguishes five; one of which, *M. Cuvieri*, was of the stature of a very stout ox; and this was not the largest species.

By the *Megalonyxes*, a new genus (*Sphenodon*), which was of the size of a hog, finds its place.

Still nearer to the Sloths must be arranged a new genus which M. Lund designates under the name of *Colodon*, and which consists of one species.

Returning to the consideration of the animals which he enumerates, and which are comprised in the order *Bruta* or *Edentata* of Cuvier, M. Lund observes,—

1. That the family of Ant-eaters properly so called, that of the Tatous, and that of the Sloths, which, at the present epoch, are peculiar to America, were also found at the preceding epoch.

2. That then, these same families were exclusively proper to this part of the world, as they are at the present epoch; and that this gives cause for thinking that no species of these three families has hitherto been found in the diluvial beds of the other parts of the world.

3. That this great order of the *Edentata* was then more numerous both in genus and species than it now is.

4. That the greater part of these mammiferous genera which once peopled the country have disappeared.

5. That every species has been destroyed, two species only exhibiting affinity, but not perfect identity, with the living species.

6. Finally, that the animals of this order attained at that epoch dimensions much greater than those which they now present.

The family of the Sloths has now entirely disappeared in the basin of the Rio das Velhas, which is explained by the want of virgin forests, all this country being occupied by the form of vegetation called by the Brazilians *Campos*. It is probable that at the epoch when these great animals lived it was otherwise, and that the country was then covered by immense forests. Everything leads to the belief

that they led the same kind of life as their analogues of the present creation, that is to say, that notwithstanding the colossal proportions of their bodies, they sought their nourishment on trees.

Such is the extract from the letter of M. Lund relating to the subject of the present article. The zoologist will look with anxiety for more detailed descriptions, which will enable him to ascertain which of the animals mentioned by M. Lund are identical with those noticed above, and give him a further insight into the species detected by this magnificent discovery. *Hoplophorus*, we presume, is the *Glyptodon* of Owen. The gigantic *Myrmecophaga* is probably the *Glossotherium* of the same author.

MEGATRE'MA, Dr. Leach's name for those species of *Pyrgoma* which have a large aperture. [CIRRIPEDA, vol. vii., p. 209.]

MEIBOM, MARC, a member of a numerous German family, who were distinguished in the seventeenth century for their classical knowledge and scientific attainments. He was born at Tonningen, in the duchy of Schleswig, about the year 1630, and died at Utrecht about the year 1711. Dr. Hutton gives 1590 as the year of his birth, and 1668 as that of his death, which are no doubt incorrect. Marc Meibom was patronised by Christina, queen of Sweden, to whom he dedicated a collection of seven Greek authors upon music. Amster., 1652, 4to. He was subsequently appointed to a professorship in the university of Upsal, by Frederick III., to whom he acted in the capacity of librarian. He quitted Upsal for the professorship of belles-lettres in the academy of Amsterdam, where he remained but a short time. In 1674 he came to England, where he prepared the publication of a new edition of the Hebrew Bible, asserting that the edition then in use was full of errors; his pretensions appear however to have been ridiculed by the learned. Among his published works, a list of which will be found in the 'Biographie Universelle,' there is a curious 'Dialogue on Proportion,' wherein he introduces the whole of the ancient geometricians, Euclid, Theon, Apollonius, &c. Many of the views advanced by Meibom in this work respecting the doctrine of proportion were shown to be erroneous by Langius, and by Dr. Wallis in a tract printed in the first volume of his works. (Hutton's *Dict.*; and *Biograph. Univer.*)

MEIGLYPTES. [WOODPECKERS.]

MEINAN, River. [SIAM.]

MEININGEN, or MEINUNGEN, the capital of the duchy of Saxe-Meiningen-Hildburghausen, is situated in 50° 35' N. lat. and 10° 24' E. long., in a pleasant valley on the banks of the river Werra, which here divides into several arms. It is a well-built town, with broad, straight, and paved streets; the ducal palace, called the Elisabethenburg, is a handsome building; the centre part is 500 feet in length, and it has two wings. It contains a library of 25,000 volumes, a gallery of paintings, a collection of engravings, and the archives of Henneberg. In a separate building in the garden there is a cabinet of medals and a collection of natural history. The other principal buildings are the house of the assembly of the Estates, the town-hall, with a good library, the four churches, an infirmary, and a theatre. There are a lyceum, a gymnasium, a seminary for country schoolmasters, and several schools. The environs are very agreeable. The inhabitants, now 6000 in number, have manufactures of black crape, yarn, calico, and woollens of various descriptions, in which they carry on a considerable trade.

MEISSEN, one of the circles of the kingdom of Saxony, is a part of the ancient Margraviate of the same name. It lies on both sides of the Elbe, between 50° 42' and 51° 26' N. lat., and 12° 45' and 14° 17' E. long. Its area is 2355 square miles, and its population 379,378 souls. This circle is one of the most fertile and best cultivated parts of the kingdom: it produces corn, fruit, flax, hemp, tobacco, hops, and in some parts wine. It likewise contains the principal manufactures in Saxony of woollen, linen, and cotton. Dresden, the capital of the kingdom, is in this circle, which is peculiarly distinguished by its natural beauties, such as the mountainous country known by the name of the Saxon Switzerland, the basaltic groups of Stolpen, and the romantic environs of Dresden. Pillnitz, and Meissen. [DRESDEN.]

MEISSEN, the second town in the circle of the same name in the kingdom of Saxony, is situated in 51° 10' N. lat. and 13° 25' E. long., on the little river Meise or Misi, on and between hills on the left bank of the Elbe, over which there

* But see above, pp. 67, 69.

is a covered bridge, supposed to have been originally built in the eleventh century; this bridge was destroyed in 1547, 1757, and in 1813, but has since been rebuilt. Meissen is one of the oldest towns in the country, having been founded in 922 (as some say, 928), by king Henry I., as a bulwark of his German settlements against the conquered Slavonians. His son, Otho I., founded the cathedral, and established a bishopric, of which the town continued to be the seat till the Reformation. There are now but few remains of the fortifications which were begun by Henry I. The cathedral, a masterpiece of ancient German architecture, has a tower surmounted with a spire 60 feet high, composed of beautiful open work. It is rich in ancient monuments. Adjoining it is the princes' chapel, founded in 1425, by Frederick the First, elector of Saxony, of the house of Meissen, for the hereditary vault of his family, in which there is a bronze monument of the founder. The palace of Albrechtsburg, near the cathedral, was formerly the common residence of the margraves, burgraves, and bishops of Meissen; but the margraves transferred their residence to Dresden in the thirteenth century. The palace was almost entirely rebuilt in 1471. Ever since 1710 it has contained the celebrated porcelain manufactory, the productions of which rival or surpass those of China and Japan in hardness, durability, the beauty of the forms, and the taste of the painting. The former convent of St. Afra, on a lofty rock, which is joined by a stone bridge to the eminence on which the palace stands, contains the prince's school, in which there are 120 scholars, most of whom live free of all expense. There are various flourishing manufactures, but the chief source of profit is the making of wine. (Reinhard, *Die Stadt Meissen*, &c.; Ursinus, *Die Domkirche zu Meissen*.)

MEISSNER, AUGUSTUS GOTTLIEB, a popular and voluminous German writer of the last century, was born at Bauzen in Upper Silesia, November 4, 1753. In 1785 he was appointed professor of æsthetics and classical literature at the university of Prague, and in 1805 director of the high school at Fulda, where he died, February 20, 1807. He wrote several dramatic pieces, including some translations from Molière and Destouches; also an abridgement in German of Hume's 'England': but it is his 'Skizzen' that rendered him a favourite with the public. These sketches, extending to fourteen *sammlungen*, or series (the first of which appeared in 1778, the last in 1793), consist of essays, tales, narratives, anecdotes, dialogues, &c.; and recommend themselves by their agreeable liveliness, shrewdness, and pleasantry. Although not entirely free from blemishes of style, they have the merit of being the most successful attempts in the lighter walks of literature which Germany could then produce. Many of these pieces were translated or imitated in French, Danish, and Dutch, and one or two were translated by Thompson in his 'German Miscellany.'

His 'Tales and Dialogues' (1781-9) may be considered as a continuation of his sketches, being similar in plan. His 'Alcibiades,' 'Massaniello,' 'Bianca Capello,' and 'Spartacus,' are productions of greater length (the first mentioned being in four volumes), and are specimens of the historical and biographical romance. With the exception of the last, they have all been translated into French. Besides the above and a variety of other works, Meissner contributed a great number of literary and historical articles to different periodicals.

MEISTERSINGERS. [GERMANY—*Language and Literature*.]

MEKINEZ. [MAROCCO.]

MEJERDA, or BA'GRADAS, is a river in Northern Africa, and probably the largest river of that continent which falls into the Mediterranean, except the Nile. Its upper course lies within the territories of Algiers; in its middle course it forms the boundary-line between that country and Tunis, and in its lower course it traverses the northern district of the last-mentioned state. A great number of rivers rise in the mountains which between 35° and 36° N. lat. and 7° and 8° E. long. constitute the most eastern of the elevated ranges of Mount Atlas: after watering a rich and populous country, which extends east of those ranges, they unite about 35° 30' N. lat., and form the Wady Serat, the principal branch of the Mejerda river. In its course, which is nearly due north, it separates Algiers from Tunis, until it reaches 36° 10' N. lat., where it is joined by the Wady Hamiz from the west, and takes the name

of Mejerda. Up to this junction its course exceeds 100 miles, and from this point it runs about 60 miles eastward through a hilly country. It then turns north-north-east, and continues this course until it falls into an inlet of the bay of Tunis near Cape Farina, after a course of more than 260 miles. The Mejerda does not appear to be navigated, but it is used to irrigate the fields in the lower part of its course, where it flows through a wide and level valley. It overflows and fertilises the adjacent country; but these inundations do not, as in the Nile, take place in the middle of summer, but in the spring. They are the effect of the winter and spring rains, and of the melting of snow on the high mountains which surround its upper branches.

MEKRAN. [PERSIA.]

MELA, POMPO'NIUS, a Roman writer on geography. He is thought by some critics to have been the same person as the Annæus Mella, or Mela, who was implicated in a conspiracy against Nero, and who put an end to his own life (Tac., *Ann.*, xvi. 17; Plin., *H. N.*, xix. 6); but this opinion is only founded on the similarity of the names. It is probable, from a passage in which Mela speaks of the recent conquest of Britain (iii. 6), that he was contemporary with the emperor Claudius; and it is evident from many passages in his work that he could not have lived before the time of Augustus (iii. 1, 'turre Augusti titulo memorabilis'; compare iii. 2, &c.). It appears from a passage in his own work (ii. 6) that he was born at Tingitana in Spain; but the MSS. differ so widely in this passage, that it is difficult to determine the right reading: many critics think that we ought to read Mellaria.

Mela's work is entitled in most MSS. 'De Situ Orbis.' It is divided into three books, and contains a very brief description of the various parts of the world. In the first book, after giving a short account of the great divisions of the earth, Mela commences with Mauritania (part of Morocco), and following generally the coast, he describes successively Numidia, the province of Africa, Cyrenaica, Egypt, Arabia, Syria, Phœnicia, Cilicia, Pamphylia, Lycia, Caria, Ionia, Æolis, Paphlagonia, and the countries on the Euxine and the Maeotis as far as the Rhiphæan mountains. In the second book he commences at the river Tanais (Don), and gives an account of the countries in Europe on the western side of the Maeotis and the Euxine as far as Thrace. He then proceeds to describe Greece, Italy, Gallia Narbonensis, and the coast of Spain as far as the Straits of Gibraltar, from which he commenced his description in the first book. The remainder of the second book is occupied with an account of the islands in the Mediterranean, Adriatic, Ægean Sea, &c. In the third book he commences again at the Straits of Gibraltar, and follows the western coast of Spain till he reaches Gaul; he then gives an account of the western coast of Gaul, and afterwards describes Germany and the central parts of Europe and Asia as far as the Caspian. After mentioning some of the islands in the ocean, he next describes India and the maritime coast of Carmania, Persia, and Arabia, and concludes with a description of the central parts of Africa.

Mela appears to have been a mere compiler, and to have had no scientific knowledge of his subject. If we consider him later than Strabo, it does not appear from Mela's work that geography had made any progress in the meantime. Like Strabo, he considers the earth as penetrated by four great inlets of the ocean, of which the Mediterranean, the Red Sea, and the Persian Gulf were three; the fourth was the Caspian Sea. The singular error as to the Caspian is the more remarkable when contrasted with the fact that Herodotus knew the Caspian to be a lake. (Herod., i. 203; Strabo, p. 121; Mela, i. 1; iii. 6.)

The best editions of Mela are by Gronovius, Leyden, 1685, frequently reprinted; by Tzschucke, 7 vols. 8vo., Leip., 1807; and the Bipont, 1809. Mela has been translated into English, by Arthur Golding, Lond., 1585 and 1590; into Italian, by Porcacchi, Ven., 1557; and into French, by Fradin, 3 vols. 8vo., Paris, 1804.

MELAIN, a name which has been given to the colouring matter of the ink of the cuttle-fish. It is obtained pure by evaporating the ink to dryness and boiling the residue successively in water, alcohol, hydrochloric acid, more water, and a little carbonate of ammonia. Dr. Prout found 100 parts of the dry residue of the ink of the cuttle-fish to be composed of—Melain, 78; carbonate of lime, 10.40; carbonate of magnesia, 7; substance analogous to mucus, 0.84; various salts, 2.16.

MELALEUCA CAJEPUTI (Roxb.), the *Melaleuca*

Minor (Smith), a native of the Molucca islands, yields the oil termed cajeput. It is obtained by distillation of the leaves and branches, which are collected the night before they are subjected to this process. It is very limpid, pellucid, and of a light or yellowish green colour. Specific gravity, 0.927; it boils at 140° (Réaumur). It is possessed of a penetrating odour; the taste is acridly aromatic, leaving a sense of coldness in the mouth. Its chemical composition is, carbon 78.12, hydrogen 11.49, oxygen 10.38. It seems to consist of two distinct oils: one transparent as water, of specific gravity 0.897; the second dark green, of specific gravity 0.920. Unrectified oil reddens litmus paper, but rectified does not. It does not detonate with iodine, nor does it form an artificial camphor with hydrochloric acid gas, but has its colour much changed by that gas. It never deposits a stearopten. Some samples of cajeput oil contain copper, which may be detected by different tests; an artificial oil is also sometimes vended, but it is not difficult to detect the fraud.

In its action on the human frame cajeput participates in the properties of other volatile oils, and is rubefacient externally, stimulant and antispasmodic when taken internally. Mixed with other ingredients it has proved a useful application to the joints in rheumatism and similar affections, while a few drops of it have often relieved or warded off slight attacks of hysteria or epilepsy. It by no means realised the expectations entertained of it as a remedy in spasmodic cholera.

MELAMPUS (Zoology), De Montfort's name for a genus of turbinated testacea (*Conovula* or *Conovulus* of Lamarck) placed by Cuvier next to the great genus *Auricula*, and by M. de Blainville and M. Rang under the family *Auriculacea*. De Blainville arranges both *Melampus* (*Conovula*) and *Tornatella* under *Pedipes* (Adanson).

This genus has, like the *Auriculæ*, plaits on the columella or pillar of the shell, but the external lip has no roll or *bourrelet*, and is finely striated internally. The general contour of the shell is that of a cone, of which the spire forms the base.

Example, *Melampus coniformis*.

Melampus coniformis, a little enlarged.

MELANCHTHON, PHILIP, (or MELANTHON, as he himself was most accustomed to write the name, according to Christ. Saxius, 'Onomast.' iii. 589), was born in the small town of Bretten or Bretheim, in the Palatinate of the Rhine, or Lower Palatinate, as it used to be called, the dominion of the elector palatine. They still show at Bretten, or did a few years ago, the house in which his parents lived. His father was George Schwarzerde, or Schwarzerdt, and is called by Melchior Adam, the earliest authority, Magister Armorum, a description which has given rise to some controversy. It appears that whatever was the original condition of Melanchthon's father, he was a man of remarkable ingenuity in his profession, and had worked his way up to a situation of some distinction, that of principal engineer to the elector, before the birth of his son. (See Bayle, *Dict. Crit.*, 2nd edit., ii. 2089, and the authorities there quoted.) According to Joachim Camerarius (in *Vit. Ph. Melan.*) he was a native of Heidelberg, and came to take up his residence at Bretten upon marrying the daughter of John Reuterus, a person who had been mayor of that town. Reuterus, who lived till his grandson was eleven years old, has the credit of having been the chief superintendent of his earliest training. On the death of his grandfather, which was followed within a fortnight by that of his father, he was sent to the college of Pfortsheim, where the remarkable progress he had already made in his studies was continued at an answerable or an accelerated rate. (See a short notice of the early life of Melanchthon in Baillet's *Enfance Célèbres*, pp. 42, 43.)

At Pfortsheim he lodged in the house of a sister of the celebrated Greek scholar John Reuchlin, who was his relation, and it was from Reuchlin, who had trans-

lated his own Teutonic surname into the Greek formation Capnio, on the supposition of its connection with Rauch (smoke), that the young Schwarzerde, a compound, meaning, in English, 'black earth,' received the more melodious Grecised appellation of Melanchthon (quasi μέλαινα χθών), intended to signify the same thing; by which alone he is now known.

After spending about two years at Pfortsheim, Melanchthon was removed in 1509 to the university of Heidelberg, which however he quitted in 1512 for that of Tübingen, where he remained till, on the recommendation of his friend Reuchlin, he was in 1518 appointed, by the elector Frederic of Saxony, professor of Greek in the newly established university of Wittemberg. This situation he held so long as he lived.

It was at Wittemberg that Melanchthon became acquainted with Luther, then occupying the chair of theology in that university. In his young colleague the great reformer found, along with a ready disposition to imbibe his opinions in religion, a piety as sincere as his own, and an erudition greatly superior; while, if Melanchthon wanted the fiery energy and boldness, and the large heart of Luther, he was free also from some of the defects apt to attend upon such endowments of strength and passion, and, by the calmness, moderation, and gentleness of his whole nature, was formed both to temper the impetuosity of his friend, and to win admittance for their common views into minds of a certain class, and that by no means the lowest, which all the powers of the other might have assailed in vain.

Thus attached by the characteristics in which they were contrasted, as well as by those in which they resembled each other, they soon became the most intimate of associates and fellow-workers. After that of Luther, Melanchthon is the most distinguished name in the history of the Reformation in Germany; and the remainder of his biography is chiefly the detail of his various labours in the promotion of that great cause. In 1519 he accompanied Luther to Leipzig, to hold a disputation on the divine original of the papal authority with Eccius, or Eckius, one of the ablest of the Catholic champions of that age. For some years after this he was actively employed, not only in writing books in defence of the reformed doctrines, but in founding schools and colleges, in visiting churches, and in other services of the same kind, undertaken at the command of the elector.

In 1530 he was appointed by the general body of the reformers to draw up what was intended to be the conciliatory Confession, or exposition of their opinions, which was presented to the emperor at the diet held at Augsburg in March that year. Both Francis I. of France, and Henry VIII. of England, were desirous of obtaining the assistance of Melanchthon in their religious reforms, but circumstances interfered to prevent him from visiting either country. In 1540 and 1541 he maintained another great disputation with Eccius, which was begun at Worms, and afterwards transferred to Ratisbon, where it was carried on before the diet, the emperor presiding in person. After the death of Luther, Melanchthon became involved in a bitter controversy with the more ardent spirits of his party, in consequence of his aversion to extreme courses, and especially the timidity he was accused of showing in his approval of the system of compromise between the two religions issued by the emperor in 1548, and afterwards known by the name of the Interim, an approval in which, whether the circumstance is to be held honourable to him or the reverse, it must be admitted that he stood nearly alone among the distinguished men of both sides. He died at Wittemberg, 19th April, 1560, leaving two sons and two daughters by his wife, the daughter of a burgomaster of that town, whom he had married in 1520, and who died in 1557. His numerous works, consisting of theological treatises, commentaries on several of the Greek and Latin classics, Latin poems, and some historical and philosophical writings, were published in a collected form in five vols. fol., at Basle, in 1544, and in four vols. fol., at Wittemberg, in 1564, again in 1580, and again in 1601.

Melanchthon principally contributed to the diffusion of the Aristotelian philosophy in Germany, both by his teaching and his writings, among which were his 'Elements of Logic and Ethics.' [ARISTOTLE, p. 336.]

MELANERPES. [WOODPECKERS]

MELANIA, a genus of fluviatile, testaceous, opercu-

lated Gastropods, placed by Lamarck in his family *Melanians* [MELANIANS]; by M. de Blainville in his family *Ellipsostomata* [ELLIPSOSTOMATA]; by Cuvier in his order *Pectinibranchiata*, between the genera *Helicina* and *Rissoa*; and by M. Rang under the order last mentioned, and in the first family of it (*Turbinés* of De Férussac), between the subgenera *Puludina* and *Rissoa*.

Generic Character.—*Animal* elongated, with a foot which is ordinarily short and not thick; head probosciform, subconical, truncated, and terminated by a buccal slit which is small and longitudinal; one pair of tentacles elongated, filiform, carrying the eyes on the external side, sometimes near the base, sometimes towards one-fourth of their length; mantle open, with festooned edges; *operculum* horny, elongated, and narrow, with an apical and paucispiral summit. (Deshayes.)

Shell with an epidermis, of an oval oblong, a pointed spire, which is often elongated or turriculated, and an oval aperture which is widened anteriorly, and has a very sharp edge.

Animal and Shell of *Melania* (*Pirena*) *aurita*. a, Operculum.

Geographical Distribution of the Genus.—The rivers of warm climates generally, and of Asia especially. Species are also recorded from Africa and North and South America. Mr. Conrad has described several new species from the rivers of Alabama.

Melania amarula.

Melania subulata.

M. Deshayes thus divides the *Melanice* —

a.

Shell oval or subturriculated.

Example, *Melania amarula*

Shell elongated, turriculated.

Example, *Melania truncata*.

γ.

Shell with the inferior angle detached.

Example, *Melania costellata*.

δ.

Shell with a bordered aperture.

Examples, *Melania marginata* and *Melania subulata*

Lamarck gives the rivers of the East Indies, Madagascar, the Isle of France, &c., as the locality of *Melania amarula*, the animal of which, he says, is very bitter, and passes for an excellent remedy for the dropsy.

The apex of all the species is generally eroded as the animal advances in age.

FOSSIL MELANIÆ.

M. Deshayes, in his Tables (Lyell, 1833), makes the number of living species thirty-four, and the number of fossil (tertiary) twenty-five. The species recorded as both living and fossil (tertiary) are, *Melanice inquinata*, *inflexa*, *Cambessedesii*, and a new species. The habitations allotted to the living species of *inquinata*, *inflexa*, *Cambessedesii*, and the new species, are, the Philippine Isles, the Mediterranean, and the lakes of Como and Geneva. *Melanice lactea*, *nitida*, and *costellata*, are noticed as fossil species found in more than one tertiary formation. In the last edition of Lamarck (1838) the number of recent species is thirty-six, and of these *M. inquinata* only is noted as occurring in a fossil state. The number of fossil species recorded in this edition is eight, and of these M. Deshayes notes the species *costellata*, *marginata*, and *nitida*, as not being *Melanice*, *M. nitida* having all the characters of the genus *Eulima*. The other two M. Deshayes keeps provisionally among the *Melanice*. *Melania semiplicata*, another of the eight, he conceives to be a variety of *M. lactea*, and is of opinion that it should be expunged from the catalogue.

Dr. Mantell records two species (*sulcata* and *costellata* ?) in the blue clay of Bracklesham. Professor Phillips notes a *Melania* ? in the Speeton clay, and two species (*M. Heddingtonensis* and *M. striata*) in the coralline oolite, *M. Heddingtonensis* and *M. vittata* in the cornbrash, and *M. Heddingtonensis* and *M. striata* in the Bath oolite. In the table at the end of his work (*Geology of Yorkshire*) he records *Melanice striata* in the coralline and Bath oolite, *Heddingtonensis* in the coralline oolite, cornbrash, and inferior oolite, *lineata* in the inferior oolite, and *vittata* in the coralline oolite and cornbrash. Dr. Fitton records *Melania Heddingtonensis* in the Oxford oolite (Dorset and Oxford).

MELANIANS, Lamarck's name for a family of fluviatile, testaceous, operculated Mollusks, breathing water only, and belonging to the order *Trachelipoda*. The family consists of the genera *Melania*, *Melanopsis*, and *Pirena*, according to Lamarck, and Mr. G. B. Sowerby, Jun. (*Conchological Manual*) suggests that to these may be added *Anculosa* and *Pasithæa*. M. Deshayes, in the last edition of Lamarck, adds the genera *Eulima* and *Rissoa* to *Melania*, *Melanopsis*, and *Pirena*, the latter of which, it seems, should be expunged.

MELANOPSIS, a genus of fresh-water, testaceous, turbinated mollusks, to which Lamarck assigns a position among his family of *Melanians*. M. de Blainville places it in his family *Entomostomata*, between *Cerithium* and *Planaxis*; and M. Rang, who includes in it the genus *Pirena*, between *Scularia* and *Planaxis*.

The genus *Melanopsis* was established by M. de Férussac, and much difference of opinion appears to have existed among zoologists as to its proper place in the series. M. Deshayes, in the last edition of Lamarck, gives it as his opinion that it should be arranged in the family of *Melanians*; and he observes that if one considers the zoological and conchological characters of the two genera *Melania* and *Melanopsis*, the conviction that they should be united soon arises. He remarks that M. de Férussac gave, in the first volume of the 'Memoirs of the Society of Natural History of Paris,' an interesting account of the animal of the *Melanopsides*, which he had observed in Spain in the neighbourhood of Seville and Valencia, and that M. Quoy has since made known the animal of *Pirena terebralis* of Lamarck; so that the means are now at hand for comparing with exactness the three principal types of the family of

Melanians, and of observing the analogy of their zoological characters.

If, continues M. Deshayes, 'we have before us a great number of species of *Melania* and *Melanopsides*, living and fossil, we remark a phenomenon entirely similar to that which we have pointed out with relation to the genera *Bulimus* and *Achatina*; that is to say, that we have seen the columellar truncation established by nearly insensible degrees from the most uncertain commencement to a notch as deep as that which marks the *Buccina*. If, in relying on the identity of the organization of the *Bulimi* and *Achatinæ*, we have been able to reduce almost to nothing the value of the character of the columellar truncation, we are authorised to employ here the same means for demonstrating the little importance which the truncation of the columella in the *Melanopsides* ought to have in the eyes of zoologists as a ground for separating them from the *Melania*. Already we have explained ourselves as to the value of the genus *Pirena*, and have shown that it was composed by Lamarck from heterogeneous materials: on one side we find true *Melania*, and on the other singular shells, approximating in their characters to certain *Cerithia* which Linnæus comprised among his *Strombi*. On approximating these species we soon find that they have all the principal characters of *Melanopsis*, and that they do not in reality differ from them, except by a notch in the right lip, which notch occupies in these species the place of the posterior gutter in the bucciform *Melanopsides*. M. de Férussac clearly perceived the relation of these shells to the *Melanopsides*, and joined them to that group, leaving in the genus *Pirena* only those which we actually comprise among the *Melania*. Thus dismembered, the genus *Pirena* should be expunged from the system.'

Geographical Distribution of the Genus.—M. Deshayes observes that the *Melanopsides* inhabit the fresh waters of the south of Europe, and particularly those in the neighbourhood of the Mediterranean; and that they show themselves abundantly in a fossil state in the greater part of the tertiary beds of Europe. He remarks that M. de Férussac has noticed that among the fossil species in our temperate countries there are some analogous to those which live in much warmer regions,—an interesting fact, from which he has been led to conclude that the lowering of the temperature had been a sufficient cause for the destruction of the races which once lived in the centre of France. M. Deshayes states that he had objected to M. de Férussac's drawing a conclusion so general from so confined a number of observations; and he thinks that, in order to establish a fact so important as that of change of temperature by the aid of observations on the mollusks, it would be necessary to find a great collection of facts, not only regarding the fresh-water mollusks, but also respecting those which inhabit the sea. He has, he says, collected these facts, and is thus able to estimate approximatively the temperature proper to each of the principal tertiary epochs.

Generic Character.—(*Melanopsis*, Fér., and *Pirena*, Lam.)—*Animal* with a probosciform muzzle and two contractile tentacula, which are conical, annulated, and each with an oculated peduncle at their external base; foot attached to the neck, very short, oval, angular on each side anteriorly; respiratory orifice in the gutter formed by the union of the mantle with the body. *Operculum* horny, subspiral.

Shell with an epidermis, elongated, fusiform or conico-cylindrical, with a pointed summit; spire consisting of from six to fifteen whorls, the last often forming two-thirds of the shell; aperture oval, oblong; columella twisted, solid, callous, truncated at its base, separated from the external border by a sinus, the callosity prolonging itself on the convexity of the penultimate whorl, forming a gutter backwards; sometimes a sinus at the posterior part of the right lip.

a.

A single sinus at the external border of the aperture, separating it from the columella. (Genus *Melanopsis*, Lam.)

Example, *Melanopsis prærosa* (*Melanopsis lanigata*, Lam., *Melania buccinoidea*, Oliv., *Melanopsis buccinoidea*, Fér.).

β.

Two distinct sinuses at the external border of the aperture, one which separates it from the columella, the other situated near the union of this border with the penultimate whorl.

Melanopsis prærosa.

Example, *Melanopsis atra* (*Pirena terebralis*, Lam., *Strombus ater*, Linn.).

Locality.—Madagascar.

Melanopsis atra.

FOSSIL MELANOPSIDES.

Mr. G. B. Sowerby, who also includes the genera *Melanopsis* and *Pirena* under the first generic appellation, says, 'We are not aware that any of the *Melanopsides* are marine, for all the recent species occur either in rivers or lakes, and yet most of the fossil species are found in beds that are considered by geologists (in this country) to be of marine formation. We know not what degree of credit is to be given to the assertion of a celebrated author, "that the greater number of the genera of the Pectinibranchia might formerly have contained species peculiar to rivers and lakes as well as to the sea," but this we do know, that wherever the fossil *Melanopsides* are found, they are accompanied by many other species of genera that at present only live in fresh water; and therefore we think they ought to be considered as characteristic of the formation in which they occur.'

M. Deshayes, in his Tables, makes the number of living species of *Melanopsis* ten, of fossil species (tertiary) eleven, and notes *Melanopsides buccinoidea* (prærosa), *Dufourei*, *costata*, *nodosa*, *acicularis*, *incepta*, as species occurring both living and fossil (tertiary). He assigns as habitations to the latter, Asia, Spain, Greece, and Laybach. Of *Pirena* he makes the number of living species three, and of fossil (tertiary) two. In the last edition of Lamarck, M. Deshayes gives nine recent species, and of these he notices *Melanopsides costata*, *prærosa*, *nodosa*, *Dufourei*, and *acicularis*? (*M. subulatus*, Sow., 'Min. Con.'), as occurring in a fossil state, observing that it is to be presumed that the species found fossil at Dax is to be distinguished from *M. Dufourei*, which occurs in a fossil state in the Isle of Rhodes. The number of species which are fossil only he makes seven. The number of recent species of *Pirena* he gives as four, but records none as fossil only. Under *Pirena terebralis* (*Melanopsis atra*) is a reference to Férussac's fossil *Melanopsides*, pl. 2, f. 7, &c.

Dr. Fitton records three species with a query, two under the names of *Melanopsis*? *attenuata* and *M.*? *tricarinata*, in the Weald-clay (Dorset), and Hastings sand (Sussex), and the third, without a name, in the Purbeck beds (Bucks).

* MELANORRHŒA, a genus of the natural family of Terebinthaceæ, tribe Anacardiaceæ, so called from the brown fluid turning black upon exposure to the air, with which every part of the principal species abounds. This tree (*M. usitata*) is familiarly known as the Burmese varnish-tree,

or theetsee, but was not described by botanists until discovered by Dr. Wallich, and figured in his splendid work 'Plantæ Asiaticæ Rariores,' t. 11 and 12. The tribe to which it belongs, abounds in plants yielding a blackish, acrid, and resinous juice used for varnishing and other such purposes, as the Marking Nut and the Japan Varnish-tree. This tree was first seen near Prome, and is found in different parts of Burma and along the coast from Tenasserim to Tavoy, extending from the latter in 14° to 25° N. lat., as Dr. Wallich has identified it with the *Kheu* or Varnish-tree of Manipur, a principality in Hindustan, bordering on the north-east frontier districts of Silhet and Tippera. It grows especially at Kubbu, an extensive valley elevated about 500 feet above the plains of Bengal, and 200 miles from the nearest sea-shore. There it attains its greatest size, some, and those not the largest, having clear stems of 42 feet to the first branch, with a circumference near the ground of 13 feet. It forms extensive forests, and is associated with the two staple timber-trees of continental India, Teak and Saul (*Tectona grandis* and *Shorea robusta*), especially the latter, and also with the gigantic Wood-oil tree, a species of *Dipterocarpus*. A second species of the genus, *M. glabra*, has been obtained by Dr. Wallich from Tavoy.

The Theetsee forms a large tree, with the habit of *Semecarpus*, and abounds in every part with a viscid ferruginous juice, which quickly becomes black by the contact of the atmosphere. Its leaves are large, coriaceous, simple, very entire, and deciduous. The panicles of flowers are axillary, oblong; those of the fruit simple and lax, with very large rufous and finally ferruginous involucre. It sheds its leaves in November, and continues naked until the month of May, during which period it produces its flowers and fruit. During the rainy season, which lasts for five months, from the middle of May until the end of October, it is in full foliage.

A branch with leaves.

At Prome a considerable quantity of varnish is extracted from this tree, but very little at Martaban. It is collected by inserting a pointed joint of a bamboo, which is closed at the other end, into wounds made in the trunk and principal boughs, which are removed after twenty-four or forty-eight hours, and their contents, which rarely exceed a quarter of an ounce, emptied into a basket made of bamboo and rattan previously varnished over. The collecting season lasts from January to April. In its pure state it is sold at Prome at about 2s 6d. for about 3½ lbs. avoirdupois. (Wallich.) Mr. Smith, who was long resident at Silhet, and was acquainted with this substance in 1812, states that it is procurable in great quantities from Manipur, where it is used for paying river-craft and for varnishing vessels designed to contain liquids. The drug, he says, is conveyed to Silhet for sale by

the merchants, who come down annually with horses and other objects of trade. In Burma, Dr. Wallich states that almost every article of household furniture intended to contain either solid or liquid food is lacquered by means of it. The process consists in first coating the article with a layer of pounded calcined bones, after which the varnish is laid on thinly, either in its pure state or variously coloured. The most difficult part consists in the drying. It is also much employed in the process of gilding: the surface, being first besmeared with this varnish, has then the gold leaf immediately applied to it. Finally, the beautiful Pali writing of the Burmese on ivory, palm-leaves, or metal, is entirely done with this varnish in its native and pure state. Some difference of opinion exists as to the effects of this juice on the human frame. Dr. Wallich states that it possesses very little pungency, and is entirely without smell, and that both Mr. Swinton and himself have frequently exposed their hands to it without any serious injury, and that the natives never experience any injurious consequences from handling its juice; but he has known instances where it has produced extensive erysipelatous swellings attended with pain and fever. Sir D. Brewster, on the contrary, considers it a very dangerous drug to handle, one of his servants having been twice nearly killed by it. (Wallich, *Pl. As. Rar.*, i., p. 9, t. 11 and 12; and *Edinb. Journ. of Science*, viii., p. 96 and 100.)

A naked fruit-bearing branch, with the large involucres.

MELANO'SIS is a malignant disease distinguished by the deposition of a peculiar soft morbid substance, of which the most prominent character is a deep brown or black colour. This substance may be deposited in separate masses, or infiltrated into the tissue of different parts of the body, or it may be effused from the blood in a fluid form into natural or morbidly formed cavities, or separated from it with the secretions. The deposition of melanotic matter generally takes place successively in numerous parts of the body, producing in all the injurious effects of compression and irritation, till it proves fatal either by its direct influence on some important organ or by the exhaustion which it gradually induces.

MELANTERITE, one of the mineralogical names for native sulphate of iron, or green vitriol. [IRON.]

MELANTHACEÆ are a natural order of poisonous Endogens, very nearly related to Liliaceæ, from which indeed they are only to be distinguished with certainty by their anthers being turned towards the sepals and petals, and by their styles or carpels being distinct or at least separable. The species vary exceedingly in their appearance, some being subterranean-stemmed herbaceous plants, producing a few flowers without their leaves just above the surface of the ground, as is the case with *Colchicum*; others forming a stem of considerable size with large leaves and numerous flowers. The consequence of this difference

in their manner of growth is a considerable difference in the appearance of the species, but they are all found to conform to the characters of Liliaceæ, with the difference above explained. Iridaceæ, to which they bear a striking resemblance, because of the similarity between *Colchicum* and *Crocus*, are readily distinguished by their inferior fruit and triandrous flowers.

The most important species of this order are medical plants, viz.: *Colchicum*, or Meadow Saffron, which is employed as a remedy for gout and rheumatism; *Veratrum album*, whose acrid poisonous rhizoma is White Hellebore; *Asagrea officinalis* and *Veratrum Sabadilla*, both of which furnish the seeds called Cebadilla, now largely consumed in the preparation of *Veratria*; and a few North American plants of less moment.

1, A diminished figure of *Veratrum Sabadilla*; 2, an expanded flower; 3, a vertical section through part of the ovary; 4 a ripe seed-vessel.

MELASOMA. [SHRIKES.]

MELASTOMACEÆ, an extensive natural order of polypetalous Exogens, nearly related to Myrtaceæ. They have opposite ribbed leaves without any trace of dots;

1, A branch of *Rhexia speciosa*; 2, a vertical section of the flower; 3, a calyx; 4, a transverse section of the ovary.

anthers prolonged into a beak, and having in the bud their points curved downwards, and inserted into sockets between the side of the ovary and that of the calyx. The ovary itself is many-celled and many-seeded, and connected with the calyx by vertical plates, which form the partitions between the sockets in which the anthers are confined. The species are extremely numerous in tropical countries, where they usually form bushes or small trees, and are scarcely known beyond the tropics, with the exception of some *Rhexias*, which straggle into North America. In Europe the order is unknown, unless in gardens, where many species are cultivated for the sake of their gay purple or white flowers. Some of the species bear berries, which are eatable, and stain the mouth a deep purple, whence their name *Melastoma*, or black-mouth; otherwise they are of no known use to man; not a trace of aromatic secretions being found in them, notwithstanding their near relationship to the aromatic Myrtaceæ.

MELAZZO. [MESSINA.]

MELCOMBE REGIS. [WYOMOUTH]

MELEA'GER. [ANTHOLOGY]

MELEAGRI'NA. [AVICULA; MALLEACEA.]

MELEA'GRIS, the generic name for the Turkeys. [TURKEY; PAVONIDÆ.]

MELES. [BADGER.] N.B. Remains of a Fossil Badger, *Meles vulgaris fossilis* (*Ursus Meles*, Linn.), occur in the Bone-caves at Lunel and in Brabant.

MELI, GIOVANNI, born at Palermo, in Sicily, about 1740, studied medicine, in which science he took the degree of doctor, and afterwards became professor of chemistry in the university of his native city. But he is best known for his poetical compositions in the vernacular dialect of Sicily, which have earned him the name of the modern Theocritus. His pastoral poems are equal, if not superior, to any compositions of the same kind which Italy has ever produced. The luxuriant beauty and variety of Sicilian scenery inspired the author, who has faithfully portrayed in his eclogues the various appearances of the seasons in that fine climate, as well as the rich tints of the sky, the bold features of the mountains and coasts, the occupations of the shepherd and the husbandman; and he has enlivened his description with love-songs, which have become popular in Sicily, and have been set to music for the favourite native instrument, the guitar. One of his finest songs, beginning

'Sti silenzi, sta viridura,
Sti montagni, sti vallati,'

is given with an English translation, and other specimens of Meli's poetry, in an article 'On the Dialects and Literature of Southern Italy,' in No. IX. of the 'Foreign Quarterly Review,' November, 1829.

Meli has excelled particularly in his 'Ecloghe Pescatorie,' or fishermen's dialogues, in which he has borrowed the peculiar language and humour of that class of people. Unlike Guarini, Tasso, and other courtly writers of pastoral poetry, Meli makes his shepherds, husbandmen, and fishermen speak their own homely and unpretending language, which is nevertheless susceptible of poetical imagery. The seventh idyll is in a loftier key: it is the lamentation of Polemuni, a man persecuted by fate, forsaken by his fellow-creatures, a despairing outcast, who is represented as seated on a lonely cliff which overhangs the deep waves that have wasted the base of the rock, and have hollowed out caves in it, within which the surge roars in dark eddies. The halcyon has built its nest on the bare sides of the cliff, and its melancholy cry is heard far over the foaming billows. Polemuni was the son of a substantial fisherman, who himself followed for a time his father's trade, had a tight gallant boat, and store of nets and tackle: when on shore he was the gayest of the gay, and the favourite of the girls of his district. Misfortune came: a storm swamped his boat, his love proved faithless, and he found himself slighted and forsaken by all. Houseless and almost naked, he is sitting on the lone cliff with his poor reed in his hand, attempting to follow his wonted occupation, while he vents his grief in song. He remembers his former happy days, and contrasts them with his present bereavement; he rails at the faithlessness of pretended friends, he sees the gloom of despair closing all around him, until at last a fearful tempest breaks forth, the waves swell beyond all bounds, and, rising in one mountain billow, overflow the cliff, and hurl the devoted victim down into the abyss of the sea.

Meli's odes, which fill the second volume of his works,

are mostly amorous, though not indecent. Some of them are exquisitely finished, such as 'Lu Labbru' (the lip), and 'Lu Pettu' (the breast). An Italian version of them has been published by Professor Rosini of Pisa, which however is inferior in gracefulness to the original.

Meli has written a mock heroic poem, under the title of 'Don Chisciotti' (Don Quixote), in twelve cantos, which is a sort of imitation of Cervantes's celebrated novel. It abounds with beauties of detail, but the ludicrous prevails throughout, and often becomes mere farce. He also wrote a volume of fables, besides satires, some of which reflect on peculiar features of Sicilian life and manners, and other minor poems. His works were collected and published at Palermo, under his own revision, in 1814, in seven volumes. King Ferdinand granted the author a copyright for ten years, and gave him also a small pension, for which the author expresses his gratitude in one of his compositions. Meli died, not long after, at an advanced age.

The Sicilian dialect has assumed, under his pen, a delicacy of refinement which places it foremost among the written languages of Italy. Some remarks on the Sicilian and other Italian dialects, with specimens of their poetical capabilities, are given in an article 'On the Study of the Italian Language and Literature,' in No. X. of the 'Quarterly Journal of Education.'

ME'LIA (Zoology), M. Latreille's name for a genus of *Cancerians* (*Lybia* of M. Milne Edwards, who has since withdrawn the name in favour of M. Latreille's prior appellation). This form approximates to *Pilumnus*, but has also some analogy with *Grapsus*.

Example, *Melia tessellata*. Colour whitish with red lines; some hairs on the feet. Length about five lines.

Locality, Isle of France.

Melia tessellata.

ME'LIA, so called from *Μελία*, the Greek name of the common ash, which one species of the genus is thought to resemble in foliage. It belongs to the natural family *Meliaceæ*, to which it has given its name, and which is, like *Melia*, characterised by having the filaments of the anthers combined into a tube, with the anthers sessile within it, and opening inwards; the seeds without wings. The species are few in number, and chiefly Indian; one is naturalised in the South of Europe, and one is found in North America; of these, *Melia Azadirachta*, the *Neem tree* or *Margosa tree* of the Peninsula of India, has been separated into a distinct genus on account chiefly of its ternary, not quinary, structure of the parts of the pistil, and its single-seeded fruit. This has been named *Azadirachta* from the Persian (*Azad-i-durukht*, the excellent tree). Its bark is bitter, and considered a valuable tonic. The fleshy part of the fruit (like that of the olive) yields a fixed oil, which is bitter, and considered anthelmintic and stimulant. The leaves are universally used in India for poultices, and both the flowers and seeds are irritating and stimulant. According to Dr. Ainslie a kind of toddy is procured by fermenting the sap of healthy young margosa-trees.

Melia Azedarach, sometimes called Persian lilac, Pride of India, and Common Bead-tree (*Hill Margosa*, by Dr. Ainslie), is said by Dr. Roxburgh to be a native of China: it is also a native of the North of India. It is much cultivated in the southern parts of the United States of America. It is called *dek* in the north provinces of India, and may be confounded with another species under the name *Azedarach* by Avicenna. When in flower it has some resemblance to the lilac, and its flowers are very fragrant. The berries are sweetish, and, though said to be poisonous, are eaten by children in the United States without inconvenience, but are reputed to be a powerful vermifuge. The bark of the root in its recent state has a bitter nauseous taste, yielding its virtues to boiling water, and is cathartic and emetic, and considered in the United States an efficient anthelmintic, and also useful in infantile remittents.

Melia Bukayun is distinguished by Dr. Royle from the West Indian *M. sempervirens* of Schwarz, with which it was

united by Dr. Roxburgh. This tree appears to be a native of Persia, though common throughout India: it is called by the Arabs *ban*, and by the Persians *azad i-durukht*. It is probable therefore that this may be one of the trees included under the *Azedarach* of Avicenna. The seeds are bitter, and considered laxative and anthelmintic, as is also the bark. *M. tomentosa* is a species found in the island of Penang, and *M. composita*, in which are included both *M. superba* and *M. robusta*, is a species found in Malabar and Mysore.

MELIA'CEÆ, a natural order of polypetalous Exogens, distinguished from all others by their stamens being united into a complete cup, within, and often below, the rim of which the anthers are inserted. It consists of trees or shrubs with alternate, often compound, leaves, inhabiting all countries within the tropics, but very rare in colder climates; the *Melia Azedarach*, or Bead-tree, a Syrian plant, now naturalised in the south of Europe, forming the principal exception. In general the species are bitter and astringent, but they are sometimes dangerously poisonous, acting violently as emetics and purgatives. Notwithstanding this, the pulpy fruit of the *Lansch* is esteemed in the Indian Archipelago, and that of *Milnea edulis* is eaten in Silhet, where it seems to resemble the Litchi and Longan of China.

1. *Trichilia spondioides*; 2, an expanded flower; 3, a ripe fruit; 4, a transverse section of the same.

MELICERTA. (Zoology.) [PULMOGRADA.] *Melicerta* and *Melicertus* are also used to designate genera of Crustaceans. [SALICOQUES.]

MELILOT, the Melilotus or Honey-lotus of botanists, so called from its smell, is a tall yellow-flowered annual. It has loose racemes of small flowers formed like those of Clover, of which it was once regarded as a species. The *Melilotus officinalis*, or *Trifolium Melilotus officinalis* of Linnæus, has long roots and a branching stem two or three feet high. It grows wild in woods, hedges, and neglected fields. When cultivated in a dry soil and made into hay, it has a powerful aromatic smell, and mixed in a small proportion with meadow-hay, gives it an agreeable flavour. This plant is used in making the Swiss cheese called *Schabzieger*. It is ground in a mill, and mixed with the curd into a kind of paste, which is put into conical moulds and there dried. [CHEESE.]

The white or Siberian melilot rises several feet high, with a strong branching stem. It was strongly recommended by Thouin in a memoir addressed to the Agricultural Society of Paris in 1788, and has been tried occasionally with some success by various agriculturists, without however having been so generally adopted for cultivation as might have been expected from the high encomiums passed upon it. It will bear four cuttings in the year, and produces a very great quantity of green fodder. It should be cut before the stems become woody, and thus it will continue several years in the ground, although it is naturally only biennial. A light and moist soil suits this plant best.

MELI'NA, Schumacher's name for the genus *Perna* of authors. [MALLEACEA, vol. xiv., p. 335.]

MELINDA, or, as it is written in Captain Owen's 'Voyages,' Maleenda, is a port situated on the eastern shores of Africa, in about 3° S. lat. and 40° E. long. It derives its chief title to notice from the first voyage of Vasco de Gama, who sailed along the eastern coast of Africa as far north as this place, where he got a pilot from the king to conduct his vessel to India. Gama describes the town as situated on a plain near the sea-shore, surrounded with gardens, and consisting of houses neatly built of hewn stone, with handsome rooms and painted ceilings. It was at that time evidently a place of some importance. In 1605 the Portuguese, under Don Francisco d'Almeida, took possession of this place, and, about twenty-three years later, they occupied Mombas also; and as the harbour of the latter is much superior, Melinda began to decline. It is not known when and in what manner it was taken from the Portuguese; but it seems that in the beginning of the last century it was in possession of the Arabs. Nor is it known in what manner it was lost by the Arabs; but when Captain Vidal visited the place in 1824, he found that the territories of the antient kingdom of Melinda were totally occupied by the Galla, a savage nation, which has carried its conquests from the southern declivity of the Abyssinian Alps as far south as Melinda. On the site of the town Captain Vidal found nothing but ruins, and he thinks that it has been entirely destroyed by the Galla in their wars against the Arabs, who possessed and still possess most of the ports along this coast. (Owen's *Narrative of Voyages to explore the Shores of Africa*, &c.)

MELIPHAGA. [MELIPHAGIDÆ.]

MELIPHAGIDÆ (Honey-suckers), a family of Tenuirostral birds. [TENUIROSTRES.]

Mr. Vigors, in his paper 'On the Natural Affinities that connect the Orders and Families of Birds' (*Linn. Trans.*, vol. xv.), thus generally refers to the *Meliphagidæ*. 'That extraordinary group, the existence of the much more considerable portion of which was unknown to the Swedish naturalist, for which there was consequently no place in his system, occupies a prominent and important situation in the ornithological department of nature. Chiefly confined to Australasia, where they abound in every variety of form, and in an apparently inexhaustible multitude of species, they find a sufficient and never-failing support in the luxuriant vegetation of that country. There the fields are never without blossom, and some different species of plants, particularly the species of *Eucalyptus*, afford a constant succession of that food which is suited to the tubular and brush-like structure of the tongue in these birds. Their numbers and variety seem in consequence to be almost unlimited. Like the *Marsupial Animals* of the same country, a group to all appearance equally anomalous, which contains within its own circle representatives of all the other groups of the *Mammalia*, this division of birds comprises every form which is observable among the families of the *Insectores*. From the powerfully constructed and strong-billed *Corvidæ* and *Orioli*, down to the slender *Merops* and the delicately shaped *Cinnyris*, every *Insectorial* group has its analogous type in this family. Their approach to the *Scansorial* tribe is strongly conspicuous. The hind toe of the greater portion of the group is long, powerful, and apparently formed for climbing, as Mr. Lewin has pointed out in his generic description of *Meliphaga* (*Birds of New Holland*). In this point of view they seem in Australasia to supply the place of the genuine *Pici*; no species of *Woodpecker*, as far as I have been able to ascertain, having hitherto been found in that country. This strong affinity to the *Scansores* is preserved by their forming one of the extremes of the present circle, which comes in contact with that tribe. I have indeed some doubts whether, in consequence of this affinity, they may not be even still more intimately united to that group, and form the immediate point of junction of the present tribe with the *Certhiada*. I have consequently entered them and their conterminous families into the tabular series with a mark of uncertainty. Time, with more accurate examination of their manners and internal economy, will clear away, it is to be hoped, these and similar points of doubt respecting groups so interesting. The following facts however are, I think, sufficiently decided, namely, that the three groups, the *Promeropidæ*, *Meliphagidæ*, and *Nectariniadæ*, constitute distinct and prominent divisions in the tribe, of which,

P. C., No. 922.

by that generally stronger and more perfect conformation which distinguishes them from the more typical families, they form the aberrant groups; that they are united among themselves by general affinities; and that they connect the tribe on each side with the conterminous tribes that approach it, that is, with the *Scansores* at the one extreme, and with the *I'issirostres*, where we first entered on the order, at the other.'

Mr. Swainson (*Classification of Birds*, vol. i.), after observing that he never had the opportunity of examining the tongue of the African Sun-birds (*Cinnyridæ*), states that by a fortunate chance he had discovered that the type among the Australian Honey-suckers (*Meliphagidæ*) which represents the *Trochilidæ*, has the tongue constructed precisely the same as in those birds. 'This brings us,' continues Mr. Swainson, 'to the second description of extensible, or rather of suctorial tongues, and which is of a form almost peculiar to the honey-suckers of Australia and its islands. In these birds the tongue is not nearly so extensible as in the *Trochilidæ*, being seldom more than half as long again as the bill; nor are the bones of the *os hyoides* carried back upon the skull, as in the woodpeckers and humming-birds. Nevertheless the structure appears especially adapted for suction; the form of the lower part is the same as in ordinary birds, but the end is composed of a great number of delicate fibres or filaments exactly resembling a painter's brush. Lewin, who drew and described these birds in their native region, has figured the tongue of the warty-faced honeysucker (*Meliphaga Phrygia*) (*Birds of New Holland*, pl. 4), and describes the bird as sometimes to be seen 'in great numbers, constantly flying from tree to tree (particularly the blue gum), feeding among the blossoms by extracting the honey with their long tongues from every flower as they passed.' What will appear still more extraordinary to the scientific naturalist is the fact that some birds of this meliphagous group are actually woodpeckers, and yet retain the typical structure of the tongue of their own natural family. The same observer, speaking of the blue-faced honey-sucker, describes it as being 'fond of picking transverse holes in the bark, between which and the wood it inserts its long tongue in search of small insects, which it draws out with great dexterity.' Now, as Lewin describes this bird as a honey-sucker, we must conclude, until facts prove otherwise, that it has the filamentous tongue of the honey-suckers, but that it is used for the purpose, not of spearing insects, but of catching them by means of the glutinous matter on the filaments, a mode of capturing its prey by no means improbable, provided the insects are of small size. It must not be supposed however that the food of the *Meliphagidæ*, several of which are as large as a thrush, and three or four much larger, is restricted, any more than that of the humming-birds, simply to the nectar of flowers. They indeed feed upon the honey, but, as Lewin declares, combined with the numerous small insects lodged in most of the flowers, which they extract in a dexterous manner with their tongues, peculiarly formed for that purpose. It is clear however, when we come to reflect upon the matter, that birds which are attached to the secretions of particular trees, as are many of the *Meliphagidæ*, can only enjoy their favourite food for a comparatively short season, that is, while the tree or plant is in blossom. They must therefore either feed at other times upon small insects or upon fruit. The two first habits we have shown them to possess; and the last, that of devouring fruits also, is exemplified in the yellow-eared honey-sucker of Lewin, who remarks that 'in the winter season these birds have been seen feeding on the sweet berry of the white cedar in great numbers.'

Mr. Swainson makes the *Meliphagidæ* the first family of the tribe *Tenuirostres*; and he thus characterizes these *Honey-suckers* :—

Bill the strongest in this tribe (*Tenuirostres*), having the mandible distinctly notched. *Feet* large, strong; the hinder toe much developed. *Tongue* extensible, generally ending in a bunch of filaments.

The following genera and subgenera are placed by this author under the *Meliphagidæ*.

Genera. *Meliphaga*. (Lewin.)

Bill moderate or short, weak; the under mandible not thickened. *Lateral toes* unequal; the inner the shortest. *Tail* rounded or graduated. *Tongue* bifid; each division ending in numerous filaments. (Sw.)

VOL. XV.—M

Subgenera:—*Meliphaga*. (Example, *Meliphaga barbata*.* 'Ois. Dor.,' pl. 57, and *M. Australasiana*.) *Ptilotis* (Sw.), leading to *Glyciphila*. (Example, 'Low. Bds.,' pl. 5.) *Zanthomiza* (Sw.). (Example, *Zanthomiza Phrygia*, Shaw. 'Zool. of N. H.,' pl. 4, the tenuirostral type.) *Anthochaera*† (Horsfield and Vigors), the rasorial type. (Example, *Anthochaera carunculata*. White's 'Voyage,' pl. 6.)

Glyciphila. (Sw.)

Habit of *Meliphaga*. Bill either shorter or slightly longer than the head; the notch in the upper mandible far removed from the tip. Tongue rather short, terminated by numerous filaments. The third and three following quills longest and nearly equal. Lateral toes equal. Tail even. (Sw.)

(Example, *G. fulvifrons*. Lewin, *N. H. Birds*, pl. 22.)

Anthomiza.

Habit of *Meliphaga*. Bill rather short. Tongue? Wings much rounded; all the quills more or less terminating in points. Tail forked. Lateral toes equal. The fissirostral type. (Sw.)

Example, *A. caeruleocephala*. ('Mus. Carl.,' i., pl. 5.)

Leptoglossus. (Sw.)

Habit of *Cinnyris*. Bill remarkably long, slender, and curved. Tongue retractile, long, bifurcated, as in *Trochilus*. Lateral toes unequal. Tail nearly even. The tenuirostral type. (Sw.)

Example, *L. cucullatus*. ('Ois. Dor.,' pl. 60.)

Ptiloturus. (Sw.)

Bill much lengthened, slightly curved; the upper mandible dilated, and folding over the base of the under; the margins of both inflected towards their tips. Nostrils lengthened; the aperture linear. Wings moderate, rounded; the first quill spurious; the four next very broad at their base, and emarginate at the inner web. Lateral claws unequal. Tail very long, graduated; the middle feathers lax and narrow. The rasorial type. (Sw.)

Example, *P. Capensis*. (Le Vaill., 'Af.,' vi., pl. 287, 288.)

Manorhina. (Vieill.)

Bill short, robust; the under mandible thickened: culmen arched, and much elevated from the base, considerably compressed its whole length; commissure curved; upper mandible notched near the tip.

Example, *M. viridis*. ('Ill. of Orn.,' pl. 78.)

Subgenera:—*Gymnophrys* (*Gymnophrys*?) (Sw.). Example, *G. torquatus*. (Lewin, 'N. H. Birds,' pl. 24.) *Eidopsarus* (Sw.). (Example, *E. bicinctus*.)

Entomiza. (Sw.)

Bill strong, moderate; culmen much elevated. Nostrils large, naked; the aperture large, oval, and placed in the middle of the bill, at the termination of the naked membrane; culmen obtuse, convex. Frontal feathers small, compact. Hind toe and claw very large, and as long as the middle toe.

Example, *E. cyanotis*. (Lewin, 'N. H. Birds,' pl. 4.)

Philedon. (Cuv.)

Culmen sharp, carinated. Head and face naked. Front with an elevated protuberance. Hind toe and claw shorter than the middle.

Example, *P. corniculatus*. (White's 'Voy.,' pl. 16.)

Myzomela. (Horsf. and Vigors.)

Bill with both mandibles very considerably curved; the sides broad and much compressed. Tongue and nostrils as in *Meliphaga*. Wings lengthened; the third, fourth, and fifth quills equal. Tail short, even. Middle toe much longer than the hinder; lateral toes equal.

Example, *M. cardinalis*. (Lewin, 'N. H. Birds,' pl. 19.) Mr. Swainson inquires whether this can be the fifth subgenus of *Meliphaga*? or an aborrent *Melithreptes*?

Mr. Vigors and Dr. Horsfield, in their 'Description of the Australian Birds in the Collection of the Linnean Society,' after remarking on the then (1826) imperfect state of knowledge with regard to this group, and the constant influx of

new species from New Holland and the Australian Islands, observe that the then known species exhibited five prominent modifications of form, according to the variation chiefly of the characters of the bill and tail, and that they wished to consider these types of form as sections only of the group which they name provisionally the genus *Meliphaga*. When the species should become more known, they express their opinions that the sections there marked out might justly be considered genera, and the higher group be denominated *Meliphagina*. 'When this subdivision takes place,' say our authors in conclusion, 'the section which stands first in our text may be considered the true *Meliphaga*.' The *Meliphaga Novæ Hollandiæ* will form the type. It may be thus characterised:—Bill rather slender, subelongate; the culmen arched, subcultrated at the base; nostrils longitudinal, linear, very narrow, covered above by a membrane, and exceeding the middle of the bill in length. Tongue furnished at the apex with many bristles. Wings moderate, somewhat rounded; first quill short; second, third, and fourth (which last is longest) gradually longer; the third and fifth, the second and sixth, equal: external beards (pogoniæ) of the third to the seventh inclusive widest in the middle. Tail subelongate, rounded. Feet rather strong; hallux subelongate, strong; acrotarses scutellated.

Example, *Meliphaga Novæ Hollandiæ*.

Mr. Caley says, 'This bird is most frequently met with in the trees growing in scrubs, where the different species of *Banksia* are found, the flowers of which, I have reason to think, afford it a sustenance during winter. In the summer I have shot it when sucking the flowers of *Leptospermum flavescens*. In the scrubs about Paramatta it is very common.'

Meliphaga Novæ Hollandiæ.

The following are the sections given by Mr. Vigors and Dr. Horsfield.

*

Tail rounded, bill rather long and slender.

Mel. Novæ Hollandiæ, Australasiana, and melanops.

* *

Tail rounded; bill rather shorter, and rather strong.

Mel. auricomis, chrysotis, and leucotis.

* * *

Tail equal, bill rather short, strong. (*Melithreptes* of Vieillot?)

Mel. chrysops, lunulata, indistincta, and brevirostris.

* * * *

Tail equal, bill rather short and slender.

Mel. cardinalis.

* * * * *

Tail equal, bill rather slender and longer.

Mel. tenuirostris, fulvifrons.

The other genera recorded by Mr. Vigors and Dr. Horsfield are *Myzantha* (V. and H.), *Anthochaera*, *Tropidorhynchus* (V. and H.), *Sericulus* (Sw.), *Mimeta* (King), *Prophodes* (V. and H.), and *Pomatorhinus* (Horsf.).

* *Certhia Novæ Hollandiæ* of old authors; and of which Mr. Swainson is led to believe *M. Sericea* is only a sexual difference.

† Mr. Swainson has the following note to *Anthochaera*:—'I hardly think it advisable to discriminate these subordinate types by subgeneric names; but as that of *Anthochaera* has been already done, I have designated what appears to me to be three of the others; the fifth I am unacquainted with.'

ME'LITA, Dr. Leach's name for a genus of Amphipodous crustaceans generally found beneath stones on the sea-shores.

Example, *Melita palmata*, *Cancer palmatus*, Montagu. Colour blackish; antennæ and feet annulated with pale greyish.

Melita palmata, enlarged.

MELITÆA. This term is employed by Peron and Blainville for a group of Medusidæ, by Lamarck and Lamouroux for Polyparia, analogous to Isis and Gorgonia. [POLYPIARIA CORTICIFERA.]

MELITHREPTUS. [MELIPHAGIDÆ; SOU-MANGA.]

ME'LITO, SAINT, was bishop of the church at Sardis in Lydia, in the second century. He is supposed by some to have been the angel of the church at Sardis, to whom St. John addressed the epistle in *Rev.*, iii. 1-6; but this conjecture is not supported by any antient writer, and it is also improbable on account of the length it assigns to the episcopate of Melito.

By Polycrates, bishop of Ephesus, in the second century, he is called 'Melito the Eunuch,' probably because he lived in celibacy, in order the better to discharge the duties of his office: the same writer adds, that he was guided in all his conduct by the influence of the Holy Spirit. (Euseb., *Hist. Ecc.*, v. 24.) Tertullian, as quoted by Jerome, praises his eloquent and oratorical genius, and says that he was thought by many to be a prophet. Yet he has been charged with heterodoxy; but upon no better ground than the titles, or perhaps a misunderstanding of the titles, of one or two of his works.

During the persecution of the Christians in the reign of Marcus Antoninus, Melito wrote an apology for them. It is addressed to the emperor, but we are not told whether it ever reached his hands. Eusebius, who has preserved an extract from this apology, places it in A.D. 170; Tillemont assigns to it the date of 175; Basnage and Lardner, that of 177.

Melito died and was buried at Sardis before the end of the second century.

Eusebius and Jerome have given lists of Melito's works, of which the most important is a 'Catalogue of all the Books of the Old Testament which are universally acknowledged.' This is the earliest catalogue of the O. T. Scriptures found in any Christian writer. It was obtained, as Melito himself informs us, in Palestine, whither he had travelled on purpose to procure it. It contains all the books at present received as canonical, except *Nehemiah* and *Esther*, of which the former is probably included under 'Esdras' (Ezra). The 'Proverbs of Solomon' are also called 'Wisdom.'

Melito wrote a book on Easter, a fragment of which is preserved by Eusebius, on the occasion of a controversy which arose in Laodicea concerning the time of keeping that feast.

All his other works are lost; but from the title of one of them, 'Concerning the Devil and the Revelation of John,' Lardner thinks it probable that he received the Apocalypse as canonical, and ascribed it to the Apostle John.

(Eusebius, *Hist. Ecc.*, iv. 26; Hieronymus, *De Vir. Illust.*; Du Pin's *Ecc. Hist.*, cent. 2; Cave's *Lives of the Fathers*, vol. i., p. 179; Lardner's *Credibility*, part ii., c. 15.)

MELIZO'PHILUS, Dr. Leach's name for a genus of Insectorial birds. [MERULIDÆ; SYLVIADÆ.]

MELLILITE, a mineral which occurs crystallized. Primary form a square prism. Scratches apatite. Colour reddish or greyish yellow. Lustre vitreous. Translucent. Specific gravity 3.24 to 3.28.

Fuses by the blow-pipe into a greenish glass; the powder gelatinizes in nitric acid. Found at Tivoli and Capo di Bove near Rome.

Analysis by Carpi:—Silica, 38.0; Lime, 19.6; Magnesia, 19.4; Alumina, 2.9; oxide of Iron, 12.1; oxide of Manganese, 2.0; oxide of Titanium, 4.0.

MELLITE. *Honey-Stone*. Occurs nodular, granular, and crystallized. Primary form a square prism. Fracture conchoidal. Hardness 2.0 to 2.5. Colour honey-yellow, orange-yellow. Streak white. Lustre resinous, vitreous. Translucent; transparent. Specific gravity 1.597. In the flame of a candle it becomes white and opaque. When more strongly heated it becomes black and falls to powder.

Found at Artern in Thuringia, in bituminous wood.

Analysis by Klaproth:—Mellitic acid, 46; Alumina, 16; Water, 38.

Mellitic Acid was discovered by Klaproth in mellite, which is a mellitate of alumina; this, when digested in carbonate of ammonia or potash, is decomposed, and the alkaline mellitate formed is to be decomposed by acetate of lead, by which mellitate of lead is precipitated, and this treated with hydrosulphuric acid is decomposed, and sulphuret of lead is precipitated, while mellitic acid remains in solution.

This acid has a sour bitter taste, is very soluble in water, and also in alcohol, and it crystallizes in colourless needle-form crystals. Neither nitric nor hydrochloric acid produces any effect upon it, but it undergoes some change when heated with alcohol.

According to Liebig and Pelouze this acid consists of—

One equivalent of hydrogen	1.
Four equivalents of carbon	24.
Four equivalents of oxygen	32.

Equivalent . 57.

MELLI'VORA. [RATEL.]

MELLON, a compound of azote and carbon, discovered by Liebig, and which, like cyanogen, consisting of the same elements in different proportions, is considered as a compound radical. When dry sulphocyanogen is heated to redness in a retort, it is decomposed; there are obtained a considerable quantity of sulphur and sulphuret of carbon, and there remains a substance of a lemon-yellow colour, which is mellon.

The properties of this substance are, that it has a yellow colour; is insoluble in water, alcohol, dilute hydrochloric or sulphuric acids; but it is dissolved and decomposed by nitric acid and the solutions of potash and soda; and with the last mentioned, ammonia is evolved. Mellon decomposes the iodide, bromide, and sulphocyanide of potassium, when fused with them, iodine, bromine, and sulphocyanogen being evolved. When heated with potassium it forms melonuret of potassium, which, being dissolved in boiling water, and nitric, hydrochloric, or sulphuric acid being added to the solution, hydromellonic acid is formed, which is precipitated, in the state of hydrate, as a dirty white gelatinous substance, which becomes yellow on drying: it is slightly soluble in water, has a weak acid reaction, and is not decomposed by hydrochloric or nitric acid.

Mellon is composed of—

Six equivalents of carbon	36
Four equivalents of azote	56

Equivalent . 92

and this, with one equivalent of hydrogen = 1, forms 1 equivalent of hydromellonic acid = 93.

MELMOTH, WILLIAM, benchet of Lincoln's Inn, born in 1666, died in 1743. The work by which his name is known is 'The great Importance of a Religious Life,' a book of which the author was not known till after his death, and which was ascribed by Walpole to the first earl of Egmont. Nichols mentions, in his 'Literary Anecdotes,' that since the death of Melmoth to his time above 100,000 copies of this work had been sold.

MELMOTH, WILLIAM, son of the above, born in 1710, died in 1799, was appointed commissioner of bankrupts by Sir Eardley Wilmot. He was twice married, first to the daughter of the well-known Dr. King, secondly to Mrs. Ogle. He was an accomplished scholar, though not educated at either University, and his translations of the Epistles of Pliny, those of Cicero to his friends, and the treatises on Old Age and Friendship, are generally allowed to be the best in the English language. These translations are made in an easy and pleasing but rather diffuse style. He was the writer of 'FitzOsborne's Letters, containing dissertations both moral and literary.' He wrote a treatise on the Christian Religion, and Memoirs of his father. Both Birch and Warton, the former in his life of Tillotson, the

latter in a note on Pope's works, mention Melmoth's translations with the highest praise. He also wrote a poem on Active and Retired Life, in Dodsley's 'Collection,' which is characterised by smooth versification and sound morality. (Chalmers's *Biographical Dictionary*; Nichols's *Literary Anecdotes*.)

MELO (Malacology), Broderip's name for a subgenus of *Voluta*. [VOLUTA.]

MELOBE'SIA, a genus of Polyparia, proposed by Lamouroux. The small porous plates of this stony substance are attached to the leaves of marine plants.

MELOCRI'NUS, a genus of Crinoidea, employed by Goldfuss in his 'Petrifacta Europæ' for some fossils of the transition limestone. It has not yet been mentioned as British. [ENCRINITE.]

MELODRAMA. [ENGLISH DRAMA, p. 409.]

MELODY (μελωδία), in music, is Air or Song—a succession of single diatonic sounds, in measured time.

Melody and Air are synonymous terms in modern music, whatever their difference may have been in that of ancient Greece; we therefore shall add but little to what we have already said on the subject under the word AIR, to which the reader is particularly referred.

The question—which exercises most influence over the mind, melody or harmony? has often been agitated, Rousseau taking the lead, who certainly has treated it eloquently, but inconsistently, acting the part of advocate on both sides, and on each refutes himself. He seems to admit, and thus to agree with Metastasio, that music is a kind of language, but overlooks the fact, that, like every other language, it can only affect those who understand it by either studying its principles, as in the case of the few, or by frequently hearing, and thus becoming empirically acquainted with it, as in the case of the many. He does not seem to have considered that simple music, that is, melody, like simple language, makes most impression on the unlearned majority, because easily understood; while complex music, namely, harmony, like high-wrought rhetoric, excites more pleasure in the minds of the instructed minority, who enter into its combinations and perceive all its relations. Melody and harmony may be said to generate each other, the one being a selection of single sounds from a harmonic source, the other a union of two or more melodies simultaneously heard. Thus both are closely connected; and Dr. Burney has remarked, that after melody and harmony have been heard together, nothing can compensate for their separation.

ME'LOE VESICATO'RIOUS. [CANTHARIS.]

MELOGALLIC ACID. The reference to this article under GALLIC ACID is a typographical error. It should have been METAGALLIC ACID. [METAGALLIC ACID.]

MELOLO'NTHIDÆ, a family of Coleopterous insects of the section *Lamellicornes*, and subsection *Phyllophagi*. This family, of which the common cockchafer (*Melolontha vulgaris*) is an example, may be thus characterised: labrum transverse, and in most instances deeply cleft in the middle; mentum as long as broad, or with the length exceeding the breadth; sometimes nearly heart-shaped, and sometimes square; the anterior margin either straight or notched in the middle, but without any projecting process or tooth; mandibles strong and horny, and having at most but a single membranous appendage, which is situated in a concavity on the inner margin; the apex truncated, and having two or three denticulations; maxillæ generally horny, and armed in most cases with five or six denticulations; antennæ usually with more than three lamellated joints; all the tarsi terminated by two claws, which are usually furnished with a spine on the under side near the base, and sometimes divided at the apex.

The family Melolonthidæ consists of three genera: *Melolontha*, *Rhizotrogus*, and *Serica*, and some subgenera of minor importance. Species of this family are found in all parts of the world. In the genus *Melolontha* the antennæ are ten-jointed; the terminal five, six, or seven joints are lamellated, and form a large fan-like appendage; in the females the lamellated joints form a smaller club than in the males, owing to their smaller size, and also to a decrease in their number, there being six, five, or four; the labrum is deeply cleft on its lower margin; the claws of the tarsi are furnished with a spine on the under side near the base; the abdomen in the male sex often terminates in a horny pointed process.

Two species of this genus are found in England, the com-

mon cockchafer (*Melolontha vulgaris*, Fab.), of which there is a figure in the article COLLEOPTERA, and the *Melolontha fullo*, a large species nearly an inch and a half in length, and which is of a blackish-brown colour, with irregular white markings. This beautiful insect is common in some parts of the Continent, but rare in this country, and has been found chiefly in the neighbourhood of Deal.

The genus *Rhizotrogus* differs from *Melolontha* chiefly in having but three lamellated joints to the antennæ, which are nine-jointed.

Rhizotrogus solstitialis, an insect which makes its appearance in the month of June, and often occurs in great abundance in some parts of this country: it very closely resembles the common cockchafer, but is of a smaller size, narrower form, and paler colour.

In the species of *Rhizotrogus*, as in *Melolontha*, the claws of the tarsi are furnished with a spine on the under side at their base; but in the next genus, *Serica*, the claws of all the tarsi are divided at the apex; the body is of a convex, ovate form, generally has a silk-like appearance, and changes in hue according with a change in the direction of the light.

Serica brunnea, a common insect in England, as well as in various parts of the Continent, is about three-eighths of an inch in length, and of a uniform pale-brown colour: the elytra are rather deeply striated, and, as well as the thorax, thickly punctured.

Serica Ruricola, another British species of the present genus, is of a black colour; the elytra are reddish-brown, and have the suture and outer margin black. This is a smaller insect than the last (being about three-twelfths of an inch in length), and of a shorter and more rounded form: it also differs in having the palpi obtusely terminated, and not acute, as in *S. brunnea*. This difference in the form of the palpi is considered by many authors of sufficient importance to separate the two insects generically, and by these authors the *S. Ruricola* is placed in the genus *Omdolopia*.

The genus *Serica* is found in all the quarters of the globe; and in M. Dejean's 'Catalogue des Coléoptères' there are sixty species enumerated.

In addition to the foregoing three groups, which appear to constitute the more typical *Melolonthidæ*, Latreille places in this family the following six genera:—

1. *Dasyus* (Lepel. et Serv.). This genus contains but few species, and appears to be confined to Brazil: they have the claws of the two anterior tarsi bifid, and those of the other tarsi entire.

2. *Macroductylus* (Latreille). In this genus all the joints of the tarsi are alike in both sexes, and all the claws are bifid. The legs are very long, and the body is of an elongated and slender form: the thorax is narrower than the elytra, and is contracted both anteriorly and posteriorly.

Macroductylus subspinosus, a common insect in some parts of North America, is about three-eighths of an inch in length; the head and thorax are black, but covered with minute yellow scales; the elytra are of a yellowish-brown colour, also covered with yellow scales: the under parts of the body are nearly white, owing to the dense clothing of scales with which they are furnished; the legs are deep-yellow, and the tarsi are black. About seven other species of the present genus are known, nearly all of which inhabit South America.

3. *Diphucephala* (Dejean). The species of this genus are confined to Australia. [DIPHUCEPHALA.]

4. *Plectris* (Lepel. et Serv.). The claws of the intermediate tarsi unequal in size; the larger of these two pairs of claws are bifid, and all the claws of the remaining tarsi are also bifid. Twelve species are known: they inhabit Brazil.

5. *Ceraspis* (Lepel. et Serv.). The species of this genus, all of which inhabit Brazil, may be distinguished by having two small notches near the middle of the hinder margin of the thorax; the space between the notches is received into a notch in the scutellum. The antennæ are 10-jointed: the claws of all the tarsi, with the exception of the anterior pair, are unequal; the larger claw of the intermediate tarsi is entire in the male sex, the other claws are bifid. In the females all the claws are bifid. The body is covered with minute scales, and is of an elongated form.

6. *Areoda* (Leach). Antennæ 10-jointed; sternum produced anteriorly; the claws of the tarsi unequal in the male sex, and equal in the females. The larger claws of the males

are bifid. The basal joints of the tarsi are short, and the terminal joint is very large, and grooved beneath. These insects are of large size, and adorned with brilliant colours. In the form of the sternum, and structure of the tarsi and claws, they depart from the true *Melolonthidæ*, and evince an affinity to the *Rutelidæ* and *Anoplognathi*, where, as in the present genus, the species have the power of folding the claws backwards against the under side of the terminal joint of the tarsus (like the closing of the blade of a pen-knife); and when thus closed, the point of the larger claws is lodged between the penultimate and antepenultimate joints of the tarsi.

Areoda lanigera, a common species in some parts of North America, is rather more than three-fourths of an inch in length, of an oval form and pale yellow colour, with green reflections: the under parts of the body are of a dark green colour, and thickly furnished with white hairs.

There are six other known species of this genus: one is found in Guadeloupe, and the remainder inhabit South America.

MELON (*Cucumis Melo*) is an herbaceous, succulent, climbing or trailing annual, cultivated for its fruit in hot Eastern countries from time immemorial. In regions where most cooling vegetables disappear on the approach of great summer heat and drought, the melon, together with the water-melon, become essential substitutes. The antiquity of the cultivation of melons being so remote, and their dispersion over large portions of Asia and Africa so extensive, their indigenous locality cannot be traced at the present day. The originals of the varieties called Cantaloup, from a place of that name about 15 miles from Rome, where melons have been cultivated since the time of the Mithridatic war, are said to have been brought from Armenia by Lucullus. In that country and Persia, melons are well known to be extremely plentiful; and their cultivation, in the open air, is supposed now to equal that which is practised in the plains of Ispahan and in Bokhara. The soil is there manured with pigeons' dung. But the varieties cultivated at and near Ispahan differ very much from the Cantaloups, which have hitherto been preferred for European culture. The Persian varieties are adapted to circumstances of soil and climate which it seems impossible to imitate artificially; for the skill of the horticulturist has been exerted in vain in attempting to produce fruit of these varieties in full perfection with regard to flavour and size.

If the roots be favourably situated, so far as moisture is concerned, the melon will bear a tropical heat; and, generally speaking, it will not succeed perfectly in the open air beyond the 43rd parallel of latitude. Its range of atmospheric temperature may be estimated at between 70° and 80°. The medium in which the roots are placed should of course be more uniform, and about 75° of bottom heat will be found both safe and efficacious.

The soil should be a fresh strong loam, not too adhesive. The topsoil of rich alluvial pasture-ground is found to answer the purpose exceedingly well, particularly where it has been overflowed in winter. If dung be used, it should be well rotted and intimately mixed with the soil; and it must not be used in such quantity as to occasion a too luxuriant growth of foliage, which in this climate would cause the fruit to be deficient in flavour.

Light is so essential, that unless the plants are kept near the glass, no tolerable degree of flavour will be acquired. As much of the direct rays of the sun should be admitted as the plants will endure, more especially when the fruit is approaching maturity. A screen may be occasionally necessary, but it should be of very thin texture.

If melon plants were not adapted for a dry atmosphere, during a considerable portion of the day at least, they could not exist in the parching climates in which they naturally grow; and therefore a free admission of air is to be recommended, so far as is consistent with the maintenance of a high temperature. The health of the plant soon suffers if evaporation by the foliage is not freely carried on; for it is found that when it is obstructed by continued moist foggy weather, disease commences, and mildew ensues. The regulation of moisture in the artificial atmosphere in which melons are grown, under an English sky, is, of all others, the most insurmountable difficulty. Covering the soil with slates or tiles or with clean gravel has been successfully resorted to as a mode of preventing the air in the frame from being at all times saturated with moisture exhaled from the soil.

Melons will thrive if their roots are actually allowed to extend themselves in water; and in the case of the floating-beds on which they are grown in some parts of Persia, they find their way through the mould and its support into the water. But a drier medium for the roots becomes essential for good flavour in the comparatively close mode which in forcing them it is necessary to adopt in this country, in order to prevent the dissipation of heat, which would otherwise take place from a limited atmosphere the temperature and elasticity of which are so much above that by which it is surrounded.

About four months may be allowed, on an average, for the period between the sowing of melons and the ripening of the fruit. The middle of January is found to be early enough to sow; and the young plants are so exceedingly tender, that accidents are then very likely to occur to them. It is on this account necessary to make successive sowings, in order to be prepared for replacement, if requisite, and also for continuing the supply throughout the summer. A sowing for the latest crops will require to be made in April. Melons may be grown by means of frames on hot-beds [HOT-BED], or in pits heated according to some of the various modes of hot-water application now so generally adopted. The seeds are sown in pans, or in small pots, and transplanted into other small pots when their seed-leaves are about half an inch broad. It is best to put only a single transplanted melon into each pot. While this is done in a separate frame, that which is intended for their future growth and fruiting is prepared for their reception, by placing small hills, rather more than a foot high, of light rich mould below each sash, and nearer to the back of the frame than the front. Care must be taken that this mould be of the proper temperature before the young plants are introduced, which is to take place when they have made a few rough leaves. As the roots extend, more soil should be added of a gradually stronger nature; and ultimately the roots should have a depth of about 15 inches of such soil. The soil should never be introduced in a cold state; and if there be no means for previously bringing it to the temperature of at least 70°, it should be put into the frame in small quantities. When water is required, it should never be much below the above-mentioned temperature, nor should it exceed 78°. It should not be applied when the air of the frame is at a high temperature from sun-heat. Shading is necessary immediately after watering, when the sun's rays have any great degree of power; unless this precaution is attended to, scorching will be induced, and the red spider will be likely to attack the foliage.

With regard to pruning and training the runners or vines of melon plants, it is necessary that a sufficient number of these for filling the frame should be made to ramify as close to the base of the main stem as can be conveniently effected by pinching off the top of the latter when it has made a few joints, or four leaves above the cotyledons; and the laterals, which in consequence become developed, may be again subdivided by a similar process. Blossoms of a monœcious character will soon after make their appearance. The male blossoms, or at least a portion of them, must be retained for the purpose of fertilisation till the requisite quantity of fruit is fairly set, after which those shoots which have only male blossoms may be dispensed with, in order to afford more space for the foliage connected with the fruit. The extremities of the fruit-bearing vines are stopped by pinching at the second or third joint above the fruit. The vines must afterwards be kept regulated so as not to overcrowd the frame with more foliage than can be duly exposed to the light. The regulation should be early and frequently attended to, so as not to have occasion to remove many vines from the plant, or divest it of much foliage at any one time. A piece of slate or tile is placed under each fruit for the purpose of keeping it from the damp soil. The heat must be fully maintained, or even considerably increased, as the fruit approaches maturity, in order to allow the admission of a more free circulation of air; but if at the same time the bottom heat be allowed to decline, the plants will become diseased and fall a prey to the mildew or to the red spider.

It has been observed that the Persian melons differ from those generally cultivated in Europe; the best account of them is in the sixth volume of the 'Transactions of the Horticultural Society.' It is there stated that 'they are found to require a very high temperature, a dry atmosphere, and an extremely humid soil. In that country we are told

that the melon is grown in open fields, intersected in every direction by small streams, between which lie elevated beds richly manured with pigeons' dung. Upon these beds the melons are planted.' It is further observed that 'the Persian gardener has therefore to guard against nothing but scarcity of water; the rest is provided for by his own favourable climate. With us the atmosphere, the ventilation, the water, and the heat are all artificial agents operating in opposition to each other.' From what has been experienced it seems in vain to attempt to bring those fruits to that delicious perfection here which they are known to acquire in their native country, except at the most favourable period of our season; for if this be chosen the two greatest essentials for producing flavour, a copious ventilation and high temperature, may be frequently combined without the latter being at the same time much counteracted by the former.

The varieties of melons can scarcely be kept permanent, particularly where many are cultivated, as they hybridise so readily. One of the finest, and perhaps the best of all, is the Beechwood melon. The Early Cantaloup, Windsor Scarlet Fleshed, Cephalonian, Green Fleshed Egyptian, Green Fleshed Italian, Early Polignac, and Golden Rock, are esteemed excellent. Of the Persian varieties the Green Hoosainee, Striped Hoosainee, and the large Germek are considered the hardiest; and the Melon of Keiseng, Melon of Nukshevan, Sweet Melon of Ispahan, and the Gereé Melon are the highest flavoured. The Dampshâ is a winter melon, or one of those varieties which are cultivated in the East, and have the property of keeping for a long time after being out.

(*Guide to the Orchard and Kitchen Garden; Transactions of Hort. Soc.; Loudon, Encyclopædia of Gardening.*)

MELO'NIA. [FORAMINIFERA, vol. x., p. 349, where the name of the genus is erroneously printed *Melonis*.]

MELO'PHUS, Mr. Swainson's name for a subgenus of *Leptonyx* (Sw.). The subgenus is thus characterised:—

General structure of *Fringillaria*, but the upper mandible is notched near its tip. Hinder claw lengthened, but rather shorter than its toe. Lateral toes equal. Tail even. Head crested. Tertials not lengthened. (Sw.)

Example. *M. erythropterus*. ('Ill. of Orn.' pl. 132.)

[FRINGILLIDÆ, vol. x., p. 483.]

MELOS. [MILO.]

MELPO'MENE. [MUSES.]

MELROSE. [ROXBURGHSHIRE.]

MELTON MOWBRAY. [LEICESTERSHIRE.]

MELUN, a town in France, capital of the department of Seine et Marne, situated on the Seine, 24 miles in a direct line south-east of Paris, or 28 miles by the road.

Cæsar, who mentions the place in his 'Commentaries' by the name Melodunum, and perhaps Metiosedum, describes it as being 'a town of the Senones, situated in an island of the Sequana (Seine), in the same manner as Lutetia (Paris).' (*B. G.*, lib. vii., c. 58.) It was taken by Labienus, Cæsar's legatus, in his campaign against the Parisii. (*Ibid.*) It was a place of note in the earlier times of the French monarchy, and was repeatedly taken by the Northmen or the English. It was taken, after an obstinate resistance by the governor Barbazân, by the English under Henry V. (A.D. 1419 or 1420); but in 1435 the inhabitants drove them out and admitted the troops of Charles VII.

The town is for the most part built on a slope on the right bank of the Seine, and, from the advantage of its situation, presents a good appearance, though neither well laid out nor well built. It has a large circular place, and two insignificant promenades. Of its two churches, that of St. Aspais is distinguished by some handsome stained-glass windows. The prefect's residence was formerly a Benedictine abbey, and there are the ruins of an old castle on the island, in which the Celtic town stood. The population in 1831 was 6604 for the town, or 6622 for the whole commune; in 1836 it was 6846. The chief manufactures are cotton yarn, printed cottons and other cotton goods, woollen cloths, druggets and serges, leather, window-glass, and earthenware. There are flour and tan mills, and lime and plaster kilns. Trade is carried on in corn, flour, wine, cheese, wool, and cattle: there is a well-frequented market for corn intended for the supply of Paris. There is much meadow-land round the town. There are a prison or house of correction, a barrack for cavalry, and a theatre; a high school, a free drawing-school, &c.

The arrondissement of Melun has an area of 390 square miles: the population in 1831 was 57,697; in 1836, 57,821 it is divided into six cantons or districts, each under a justice of the peace, and comprehends 105 communes.

MELVILL, or MALEVILL, GEOFFREY DE, of Melville Castle, in the shire of Edinburgh, first appears in the records about the middle of the twelfth century, when he is designated by King Malcolm IV., 'Vicecomes meus de castello puellarum,' that is to say, sheriff of Edinburgh. There was then no sheriff of the shire of Edinburgh; none had yet been constituted, nor for some time afterwards; and the public business was in all likelihood principally transacted in the castle, of which he was said to be sheriff.

In the same reign and forwards to the year 1171, Melville was lord-justiciar of 'Scotland,' then strictly so called, or the territory of the king of Scots north of the Frith of Forth; the district south of the Forth (once a part of Northumberland) long continuing a distinct territory under the name of 'Lothian,' and having its own separate justiciar. Melville is the earliest justiciar of Scotland yet discovered in our records. The time of his death is uncertain. He had a younger son Philip, who by his marriage obtained the barony of Monethyn in the Mearns. Philip de Malovill, the son of the said Philip, was sheriff of the Mearns about the year 1200. In 1222 he was made sheriff of Aberdeen; and in 1240 a joint-justiciar of Scotland with Richard de Montalt.

MELVILLE, SIR JAMES, is supposed to have been born in the year 1535. He was the third son of Sir John Melville of Raith, one who early joined the party of the Reformation in Scotland, and after suffering from the animosity of Cardinal Beaton, at length fell a victim to his successor, Archbishop Hamilton, in 1549. Young Melville, then about 14 years old, was upon this, it seems, sent by the queen dowager's influence and direction, and under the protection of the French ambassador returning to France, to be a page of honour to the youthful Mary, queen of Scotland. He appears, however, to have rather continued in the ambassador's employ till 1553, when he got into the service of the constable of France. He afterwards made a visit to the court of the Elector Palatine, and being well received, remained there for some time, but ultimately came to Scotland. It would be a profitless task to follow the knight in all his missions and movements. He was a courtier in the strict sense of that term, one to whom a court was the whole world, and its principles of action the great code of duty. He appears to have had a high idea of his own importance, and sometimes blames himself for the unfortunate temper, which he says he possessed, of finding fault with the proceedings of the great. All this and much more we learn from the elaborate memoirs of his own life and times, which he was careful to write for the benefit of posterity. Two mutilated editions of this curious work were published in English, besides a French translation, but an accurate edition has been recently published from the original manuscript. Sir James died on the 1st November, 1607.

MELVILLE, ANDREW, was born on the 1st August, 1545. He was the youngest of nine sons, children of Richard Melville of Baldov, a small estate on the banks of the South Esk, near Montrose; and he had the misfortune to lose both his parents when only about two years old, his father falling at the battle of Pinkie in 1547, and his mother dying in the course of the same year. The care of young Melville devolved upon his eldest brother, who was minister of the neighbouring parish of Maritoun after the establishment of the Reformation in 1560. The year preceding this, Melville, then at the age of fourteen, was removed from the grammar-school of Montrose, where he had been for some time, to St. Mary's College, in the university of St. Andrew's. This place he left in 1564, with considerable reputation for his proficiency in philosophy and the languages, and repairing to the Continent, entered himself a student in the university of Paris, where he remained two years, when, in order to acquire a more perfect knowledge of the civil law, he proceeded to Poitiers. He had scarcely arrived there when, such was the opinion entertained of him, that though a stranger and only twenty-one years of age, he was made a regent in the college of St. Marceon. He continued in this situation for three years, prosecuting at the same time the study of the law, when, on account of the political disturbances of the place, he retired to Geneva, and was there, by the influence of Beza, appointed to the

chair of humanity in the Academy, which happened to be then vacant. When he received this appointment he was, as to pecuniary means, in a state of almost total destitution. Leaving his books and other effects behind him, he had set out on his journey to Geneva on foot along with a young Frenchman, who wished to accompany him, and on reaching their destination the joint fund of the two travellers did not exceed a crown. The quarter's salary, which was advanced to Melville at his admission to the chair, proved accordingly a most seasonable relief. Geneva was a scene to which the mind of Melville often recurred in after-life. It was there he made that progress in Oriental learning for which he became so distinguished. There also he enjoyed the society of some of the best and most learned men of the age; but above all it was there the hallowed flame of civil and religious liberty began to glow in his breast, with a fervour which continued unabated ever after. He left Geneva in the spring of 1574, at the urgent request of his friends at home, and returned to his native country after an absence altogether of about ten years. On this occasion Beza addressed a letter to the General Assembly, in which, among other expressions of a like kind, he declared that Melville was 'equally distinguished for his piety and his erudition, and that the Church of Geneva could not give a stronger proof of affection to her sister church of Scotland than by suffering herself to be bereaved of him that his native country might be enriched with his gifts.'

It was about this time Melville seems to have made his first appearance as an author. His earliest publication consisted of a poetical paraphrase of the 'Song of Moses,' and a chapter of the Book of Job, with several smaller poems, all in Latin, and worthy of the disciple of Buchanan,* especially his 'Carmen Mosis.'

On Melville's arrival in Edinburgh, in July, 1574, he was invited by the regent Morton to enter his family as a domestic tutor; but this invitation was declined by Melville, who was averse to a residence in court, and preferred an academic life. He was early gratified in this wish; for shortly afterwards he was appointed by the General Assembly Principal of Glasgow College. Here his learning, energy, and talents were eminently serviceable, not only to the university over which he presided, but to the whole kingdom and to literature in general. He introduced improvements in teaching and discipline, of great importance, and infused an uncommon ardour into his pupils. His very table-talk and conversation were so interesting and instructive that the master of the grammar-school, who was afterwards principal of the college, used to say 'he learned more of Mr. Andrew Melville, cracking and playing, for understanding of the authors which he taught in the school, than by all his commentators.' It was not however as a mere scholar or academician that Melville was distinguished. He took a prominent part in the ecclesiastical disputes of the time, and was active in the church courts and in the conferences held with the parliament and privy-council on the then much agitated subject of church government. To him is generally ascribed the overthrow of episcopacy at that time and the establishment of presbytery, and he commonly went afterwards by the name of *Episcopomastix*, or the Scourge of bishops. His intrepidity was often very remarkable. On one occasion, when threatened by the regent Morton in a menacing way, which few who were acquainted with his temper could bear without apprehension, Melville replied, 'Tush, man! threaten your courtiers so. It is the same to me whether I rot in the air or in the ground; and I have lived out of your country as well as in it. Let God be praised; you can neither hang nor exile his truth!'

Another matter to which the attention of the General Assembly was at this time directed was the reformation and improvement of the universities. Here Melville also took a leading part. At the end of the year 1580 he was translated from Glasgow to be principal of St. Mary's College in the university of St. Andrew's, where he distinguished himself by his usual zeal and ability. Besides giving lectures on theology, he taught the Hebrew, Chaldee, Syriac, and Rabbinical languages, and his prelections were attended not only by young students in unusual numbers, but also by several masters of the other colleges. In these scholastic labours however he did not lose sight of the condition of the Church, and being called on to open an extra-

ordinary meeting of the General Assembly in 1582, he inveighed in his sermon in strong terms against the arbitrary and oppressive measures of the court. His boldness gave offence to the regent, and shortly afterwards he was cited before the privy-council on a charge of high-treason founded on some expressions which it was alleged he had made use of in the pulpit. The charge was not proved; but being determined to silence him, the privy-council found him guilty of behaving irreverently before them, and sentenced him to imprisonment, and to be further punished in his person and goods as his majesty should see fit. Fearing his death was ultimately intended, he was urged by his friends to make his escape, and accordingly leaving Edinburgh he went first to Berwick and then to London, where he remained till about the end of the year 1585, when the indignation of the kingdom having driven Arran from the court, Melville returned to Scotland after an absence of about twenty months, and resumed his former station in the university. His sincerity and zeal however were by no means agreeable to the king, who wished to assume an absolute control over the affairs of the Church; and in order to accomplish his wish to get rid of him, the king had recourse to one of those stratagems which James thought the essence of 'king-craft.'

In May, 1606, after the king had ascended the English throne, Melville received a letter from his majesty desiring him to repair to London that his majesty might consult him and others of his learned brethren on ecclesiastical matters. Melville and others went accordingly, and had various interviews with the king, who at times condescended even to be jocular with them; but they soon learned that they were interdicted from leaving the place without special permission from his majesty. Melville having written a short Latin epigram, in which he expressed his feelings of contempt and indignation at some rites of the English church on the festival of St. Michael, was immediately summoned before the privy-council, found guilty of *scandalum magnatum*, and, after a confinement of nearly twelve months, first in the house of the dean of St. Paul's, and afterwards in that of the bishop of Winchester, was committed to the Tower. Here he was kept a prisoner till the month of February, 1611, a period of about four years, when, at the solicitation of the duke of Bouillon, who wished his services as a professor in the university of Sedan, he was permitted to depart the kingdom.

In 1620 his health, which had previously been slightly impaired, grew worse, and in the course of the year 1622 he died at Sedan, in the seventy-seventh year of his age, but under what circumstances is not accurately known.

Melville appears to have been low in stature and slender in his person, but possessed of a sound constitution and great physical energy. His voice was strong, his gesture vehement, and he had much force and fluency of language, with great ardour of mind and constancy of purpose. His natural talents were of a superior order; and, in the concluding words of his biographer, 'next to the Reformer I know no individual from whom Scotland has received such important services, or to whom she continues to owe so deep a debt of national respect and gratitude as Andrew Melville.' (*McCrie's Life of Melville.*)

MEMBRANE (in Anatomy) is an expansion of any tissue in a thin and wide layer. Since the time of Bichat [*BICHAT*], the membranes have been generally enumerated as of three kinds, the serous, the mucous, and the fibrous, which are distinguished as well by their physical characters and their functions, as by the diseases to which each is peculiarly subject.

The serous membranes are so named from the character of their secretion, which consists of a very small quantity of thin serous fluid. In the adult condition of man and the higher vertebrata, they form what are called shut sacs. In each of the cavities of the chest, for example, which are exactly filled by the lungs, there is a serous membrane, the pleura, which lines the walls of the chest, and is then reflected on and covers the surface of the lung; and thus there is enclosed between the surface of that part which lines the chest, and of that which envelopes the lung, an extremely narrow space, a sac, into which a very small quantity of fluid is secreted. During respiration there is a constant friction between the lung and the walls of the chest, which the fluid, by its lubrication of their surfaces, renders easy. It is the general condition of serous membranes, that they exist, with the single exception of the conjunctiva of the eye [*EYE*], wherever there is friction between the

* In a copy of verses addressed to Buchanan, Melville calls him his master: 'Andreas Melvinus Geo. Buchanano preceptor suo et Musarum parenti.' To what period this alludes however, we have no precise information.

surface of an organ and the cavity in which it is contained. They are adapted for this condition by possessing a remarkably smooth polished surface, covered by a very fine layer of epithelium, through which their moistening secretion can easily pass. The basis of their structure is a fine and rather loose cellular tissue, which by boiling is at once converted into gelatine. The serous membranes in man are, the arachnoid, which is found in the cerebro-spinal cavity [BRAIN], lining the dura mater, and covering the brain and spinal chord, and lining the ventricles; the pleura, lining the chest and covering the lungs [RESPIRATION]; the pericardial serous membrane, similarly related to the heart and its investing sac [HEART]; the peritoneum, lining the abdominal walls and covering the abdominal part of the digestive canal, the liver, spleen, part of the pancreas, &c.; and the tunica vaginalis, forming the sac of the testis.

The synovial membranes, by which joints are lined, and the heads of bones which move on each other covered, may be regarded as a modification of serous membranes, differing from them chiefly in the character of their secretion and in some of their diseases. [ARTICULATION.]

A membrane very similar to the serous lines the whole vascular system, and forms the internal membrane of the arteries, veins, lymphatics, and lacteals, forming a closed cavity with innumerable ramifications, and affording, with its polished surface and fine epithelium, the least possible obstacle to the movement of the circulating fluids.

The mucous membranes, like the serous, are named from their peculiar secretion. [MUCUS.] While the serous membranes line all those cavities whose surfaces are in contact with living parts, the mucous membranes line those canals and cavities which, in the adult condition of man and the higher vertebrata, are exposed to the contact of the air and other inorganic substances. The basis of these membranes is a compact cellular tissue, which does not yield gelatine in boiling, and whose areolæ do not contain fat. Their epithelium is thicker than that which covers serous membranes, but thinner than the epidermis covering the skin, to which they are in many respects similar. In the parts where they line the organs of sense, the mucous membranes are generally beset with fine nervous papillæ; in other parts, numerous glands for peculiar secretions open on their surface by orifices through which the membrane is continued up the branches of the ducts into the very substance of the gland. [GLAND.] Nearly all the tracts of mucous membrane in man communicate with each other: they are, the nasal, which lines the cavities of the nose; the conjunctival, which covers the front of the eye-ball and lines the eye-lids, and opens by the lacrymal duct into the nose [EYE; LACHRYMAL GLAND]; the auditory, which lines the cavities of the ear [EAR] and opens into the pharynx; the digestive, including that which lines the mouth, œsophagus, stomach, intestines, and the several glands whose ducts open into this canal; the respiratory, which lines the larynx, trachea, and bronchial tubes [RESPIRATION]; the urogenital; and the mammary.

The fibrous membranes are those which are chiefly formed of tendinous tissue. They serve either to form strong cavities for the protection of important parts, as the pericardium, the dura mater, the fibrous capsules of joints, the sheaths of tendons, &c., or to envelop and strengthen certain parts, as the periosteum, fasciæ, &c.; or they are merely expanded tendons, as aponeuroses. They are tough and inelastic membranes, composed of the shining dense wavy fibres which constitute the usual structure of tendons, mixed with more or less of a dense cellular gelatinous tissue.

MEMBRANI'PORA. [POLYPIARIA MEMBRANACEA.]

MEMECYLA'CEÆ are a very small natural order of Polypetalous Exogens, consisting of a few tropical plants of little interest. Most of them inhabit the East Indies, the Isle of France, and Madagascar. They are in habit and foliage like Myrtaceæ, with which order they agree in most respects; but they have anthers which in form resemble those of many Melastomaceæ, and the leaves have no transparent dots. From the latter order they are distinguished by their leaves not being ribbed, and by their cotyledons being convolute. In the opinion of Brown and Chamisso, it is rather as a section of Melastomaceæ than as a peculiar order that Memecylaceæ are to be accounted. No useful properties have been assigned to any of the species, except to Memecylon edule, an East Indian plant, whose leaves are an ingredient in the dyes of Coromandel,

according to Roxburgh, and whose ripe astringent pulpy black berries are eaten by the natives.

MEMEL, River. [NIEMEN.]

MEMEL (called Klaipeda by the Lithuanians), the capital of the circle of the same name, in the government of Königsberg, in East Prussia, is situated in $55^{\circ} 42'$ N. lat. and $21^{\circ} 5'$ E. long. It is the most northern town in the Prussian dominions; and being only 13 miles from the frontiers of Russia, has long been the centre of a very extensive contraband trade with that empire, which has however been extremely restricted by the very rigorous measures employed by the Russian government. It is situated at the mouth of the little river Dange (pronounced Danie), near the Kurisches Haff, which is connected by a narrow channel with the Baltic. The harbour, which is good and safe, is defended by the citadel. Before it there is a lighthouse, 73 feet high, on a sand-hill. Memel is extremely well situated for commerce; and the number of ships that annually visit it may be taken at 700 on an average, of which at least two-thirds are British. The principal articles of exportation are:—timber, which is brought down in floats; hemp, flax, corn, hides, tallow, bristles, wax, feathers, and yarn. The imports are chiefly colonial produce and calicoes. There are breweries, distilleries, soap-manufactories, and saw-mills. The town was formerly well fortified; but only a part of the works now remain, and no use is made of them. There are several public offices and public schools; the churches are four in number, viz. one German Lutheran, one Lithuanian Lutheran, one Roman Catholic, and one Calvinist. None of the public buildings are remarkable. The town is however on the whole regularly built. The population, by the census of 1837, was 9034. Memel is likewise the German name of the river Niemen.

(A. G. Preuss, *Beschreibung von Preussen*, 8vo., 1835; Stein; Hirschelmann.)

MEMINNA, a genus of the subfamily *Moschina* (Gray). [MOSCHIDÆ.]

MEMNON, a personage frequently mentioned by Greek writers. He is first spoken of in the 'Odyssey,' as the son of Eos, or the morning, as a hero remarkable for his beauty, and as the vanquisher of Antilochus. (iv. 188; xi. 521.) Hesiod calls him the king of the Ethiopians, and represents him as the son of Tithonus. (Th., 985.) He is supposed to have fought against the Greeks in the Trojan war, and to have been killed by Achilles. In the *Phuocraia*, a lost drama of Æschylus, the dead body of Memnon is carried away by his mother Eos. (Fragm., No. 261, Dindorf.) He is represented by most Greek writers as king of the Ethiopians, but he is also said to have been connected with Persia. According to Diodorus (ii. 22), Tithonus, the father of Memnon, governed Persia at the time of the Trojan war, as the viceroy of Teutamus, the Assyrian king; and Memnon erected, at Susa, the palace which was afterwards

known by the name of Memnonium. Diodorus also adds that the Ethiopians claimed Memnon as a native of their country. Pausanias combines the two accounts: he represents Memnon as king of the Ethiopians, but also says that he came to Troy from Susa, and not from Ethiopia, subduing all the nations in his way. (Paus., x, 31, § 6; i. 42, § 2.) Æschylus also, according to Strabo, spoke of the Cissian, that is, Susian, parentage of Memnon (xv., p. 720); and Herodotus mentions the palace at Susa, called Memnonia, and also says that the city itself was sometimes described under the same name. (Herod., v. 53, 54; vii. 151.)

The great majority of Greek writers agree in tracing the origin of Memnon to Egypt or Ethiopia in Africa; and it is not improbable that the name of Memnon was not known in Susa till after the Persian conquest of Egypt, and that the buildings there called Memnonian by the Greeks were, in name at least, the representative of those in Egypt. (British Museum, *Egyptian Antiquities*, i., p. 267.) The partial deciphering of the Egyptian proper names affords us sufficient reason for believing, with Pausanias (i. 42, § 2), that the Memnon of the Greeks may be identified with the Egyptian Phamenoph, Phamenoth, Amenophis, or Amenothph; of which name the Greek is probably only a corruption. Phamenoph is said to mean 'the guardian of the city of Ammon,' or 'devoted to Ammon,' 'belonging to Ammon.'

Memnon then must be regarded as one of the early heroes or kings of Egypt, whose fame reached Greece in very early times. In the eighteenth dynasty of Manetho the name of Amenophis occurs, with this remark:—'This is the one who is supposed to be the Memnon and the vocal stone.' He is Amenophis II., and the son of Thutmosis, who is said to have driven the shepherds out of Egypt.

There are many colossal statues in Egypt, which have been called Memnonian, of which the most celebrated is the vocal statue described by Strabo and Pausanias. At sunrise a sound was said to proceed from this statue, which Pausanias compares to the snapping of a harp or lute (i. 42, § 2). Strabo states that he heard the sound himself, in company with Ælius Gallus (p. 816); and Tacitus relates that Germanicus also heard the sound. (Ann., ii. 61.) This statue is identified, by the descriptions of Strabo and Pausanias, with the northernmost of the two colossal statues in the Theban plain, on the west bank of the Nile. Its height, according to modern travellers, is about 50 feet; and its legs contain numerous inscriptions in Latin and Greek, commemorating the names of those who had heard the sound. Most of these inscriptions belong to the period of the early Roman emperors. There is some difficulty however, notwithstanding these inscriptions, in identifying this statue with the one described by Strabo and Pausanias. These writers say that the upper part had in their time fallen down; but at present the upper part exists in its proper position, though not in a single piece. Heeren conjectures that the broken statue might have been repaired after the time of Strabo. With respect to the sounds supposed to come from this statue, it is conjectured that they were caused by some trickery of the priests. 'Alexander Humboldt speaks of certain sounds that are heard to proceed from the rocks on the banks of the Oronoko at sunrise, which he attributed to confined air making its escape from crevices or caverns, where the difference of the internal and external temperature is considerable. The French *sarans* attest to having heard such sounds at Carnak, on the east bank of the Nile; and hence it is conjectured that the priests, who had observed this phenomenon, took advantage of their knowledge, and contrived, by what means we know not, to make people believe that a similar sound proceeded from the colossal statues.' (British Museum, *Egyptian Antiquities*, vol. i., p. 266.)

The head of the colossal Memnon in the British Museum has no claim to be considered as the vocal Memnon described by Strabo, Tacitus, and Pausanias. The height of the figure to which the head belongs was about 24 feet when entire. There is also an entire colossal Memnon in the British Museum, 9 feet 6½ inches high, which is a copy of the great Memnon at Thebes.

(Hamilton's *Egyptiaca*; British Museum, *Egyptian Antiquities*; *Philological Museum*, No. 4, art. 'Memnon.')

MEMNON, of Rhodes, was the brother of the wife of Artabazus, the satrap of Lower Phrygia, and was advanced, together with his brother Mentor, to offices of great trust and

power by Darius Ochus, king of Persia. We are ignorant of the time of Memnon's birth, but he is mentioned by Demosthenes as a young man in B.C. 352. (*Aristocrat.*, p. 672.)

Memnon possessed great military talents, and was entrusted by Darius, the last king of Persia, on the invasion of Asia by Alexander of Macedon, with an extensive command in western Asia; but his plans were thwarted and opposed by the satraps, and it was contrary to his advice that the Persians offered battle to the Macedonians at the Granicus. After the defeat of the Persians at the Granicus, Memnon was appointed to the chief command in western Asia, as the only general who was able to oppose the Macedonians. He first retired to Miletus, and afterwards withdrew to Halicarnassus in Caria, which he defended against Alexander, and only abandoned at last when it was no longer possible to hold out.

After the fall of Halicarnassus, Memnon entered into negotiations with the Lacedæmonians, with the view of attacking Macedonia. He was now completely master of the sea, and proceeded to subdue the islands in the Ægean. He took Chios, and obtained possession of the whole of Lesbos, with the exception of Mitylene, before which place he died, B.C. 333. The loss of Memnon was fatal to the Persian cause: if he had lived he would probably have invaded Macedonia, and thus have compelled Alexander to give up his prospects of Asiatic conquest, in order to defend his own dominions.

(Arrian; Diodorus Siculus; Quintus Curtius.)

MEMNON, a Greek historian of Heraclea in Bithynia, lived in the first or second century of the Christian æra. He wrote a history of the tyrants of his native town, of which considerable extracts have been preserved by Photius; these extracts have also been published separately. The best editions are by Orellius, Leip., 1816. They have also been translated into French by the Abbé Gêdoyn, in the *Mém. de l'Acad. des Inscriptions*, vol. xiv., p. 279-333. Photius was not acquainted with the first eight books of Memnon's History, nor with those which follow the sixteenth book. (Phot., c. 224.) The 'Excerpts' of Photius embrace a period from the assassination of Clearchus to the death of Bithagoras, which was at least later than 45 B.C.

MEMOIRS, a term, in its application to a particular species of writing, of French origin, and in appearance properly signifying, as its obvious etymology would denote, a narrative or account mainly or primarily intended for no higher purpose than that of simply recording the facts it embraces, or addressing the one faculty of the memory. Perhaps the modern memoirs may be held to answer pretty nearly to what the Romans understood by *Commentarii* or *Commentaria* (see the meanings of this word in Facciolati, *Lexic.*), unless when that title was given, in genuine or affected modesty, to writings of a more artificial character than that to which it rightly belonged. The philosophical ends, and the gratification of the imagination and the taste, aimed at in what is properly called a history, are not therefore to be looked for in memoirs, which, when they relate to historical subjects, are in truth not so much history as materials for history. A common description of French works of this kind is *Mémoires pour servir* (i.e. *à l'histoire*). Most frequently too, but not universally, memoirs detail events in which the writer himself has been personally concerned. Very often the work is purely biographical, and not historical at all; and sometimes materials for biography only, and not a biographical work in the proper sense of the term. Sometimes it is neither historical nor biographical, but merely a discourse or statement on some point in science or literature; of this kind are the published memoirs of many academies ('*Mémoires de l'Académie des Inscriptions*,' for instance), and other literary or scientific societies. It may be noted, that when Horace Walpole wrote his amusing account of the last ten years of the reign of George II., probably soon after the middle of the last century, the word 'Memoires,' which is the title he has given his work, was still so far from being completely naturalised among us, that he has retained the French spelling. At the same time, we have several English memoirs—such for instance as 'Memoires of the Reign of King Charles I.,' by Sir Philip Warwick, 1701; 'Memoirs concerning the Affairs of Scotland,' by George Lockhart, Esq., 1714; 'Memoirs of John Ker, of Kersland,' by himself, 1726, &c. The French language is particularly rich in those kinds of historical and biographical materials which are expressed by the term *Mémoires*.

MEMORIAL. [ANNUITY.]

MEMORY is a name given to one of what are called the faculties of the mind,—the faculty (as it is otherwise expressed) of remembering or recollecting. The word is used to denote at the same time the operation or act of remembering, the state of the mind when it exercises the faculty, as distinguished from the faculty itself; but this last is a derived and by far the rarer use of the word.

What ideas are, how they are first generated, and how afterwards reproduced, are matters the explanation of which belongs to other articles. [IDEA; SENSATION; ASSOCIATION.] But when an idea is reproduced in the mind by any of the ordinary modes of association, and there co-exists with this idea the idea of its having been before present in the mind, this complex state of mind is a case of memory. We are then said to remember the thing (whatever it may be), the idea of which is thus present to the mind. This is an exercise of the faculty of memory.

Mr. Stewart seeks to make a distinction between the memory of events and the memory of things, on the ground that in the former case alone does the idea of past time form part of the complex state of mind. This does not seem to be correct. In all cases of memory, in the memory of things as well as of events, there is (as has been said) the idea of the idea which is now present to the mind having been present before. And this idea is obviously a complex idea, of which the idea of the previous time and the idea of the interval between that and the present time are parts. The particular idea of past time, by means of which Mr. Stewart seeks to make his distinction, belongs to the event that is remembered, and has evidently nothing to do with the mental phenomenon of memory. It is the idea of the event having taken place at a past time, and not (which alone is concerned with the mental phenomenon of memory) the idea of the idea of this event having been before present to the mind.

There is a distinction between *remembering* and *recollecting*, which, though not always observed in conversation, it is yet worth while to notice. The ideas that are remembered either come into the mind without any effort on the part of the person remembering, or with such effort. In the first case the person is more properly said to remember; in the second to recollect. The effort of recollection may be generally described as consisting in seeking out for different ideas which are likely to recall, by any of the ordinary modes of association, the desired idea. What these modes of association are has already been fully explained in two previous articles, ASSOCIATION and DREAMS.

It will be seen that the thing which is essential to the faculty of memory, and which distinguishes it from other faculties of the mind, that indeed which the faculty of memory may be said to be, is the faculty of recognising an idea which has before been present to the mind, as having been before present. But this faculty of recognition can never be exercised until the idea that is to be recognised has been introduced by one of the ordinary modes of association. Thus the principle or (as it may also be called) the faculty of association is necessary to the exercise of the faculty of memory. This principle of association, which, though necessary to the exercise of the faculty of memory, is yet only accidentally connected with that faculty, becomes consequently the basis of mnemonics, or the art of recollection.

The principle of all systems of mnemonics, however much these may differ in complexity, is the same, and simple. It is to select a number of objects which, whether of themselves or by reason of the order of selection, are more easily remembered than those which it is our object to remember, and to associate in our minds each one of the latter set with some one of the former. One of the simplest systems of mnemonics is the plan which used to be resorted to by the ancient orators, of connecting in their minds the different parts of a speech with different parts of the building in which it was delivered. The different systems of *Memoria Technica* which have been put forth in later times are more complex specimens of the art. Of these, or of any one of these, it is unnecessary to give a detailed account here. One of the best known is that of Dr. Grey (Lond., 1730).

MEMPHIS. [EGYPT.]

MENA, JUAN, the best Castilian poet of the fifteenth century, was born about 1412 at Cordova, the 'alma ingenuorum parens,' as Nicolas Antonio calls it, on account of its numerous authors, especially Latin, Arabic, Hebrew, and Castilian poets. Although Mena did not show an ardent love of letters till he attained his twenty-third year,

yet he so quickly and fully stored his mind, both in his native city and at Salamanca and Rome, that he was much courted by the elegant poet the Marquis of Santillana, Don Enrique de Villena, the constable Alvara de Luna, and the rhymesters who attended Juan II. This king appointed Mena his Latin secretary, and, what is more, his historiographer, a most honourable office, which was instituted by Alphonso X., 'el Sabio,' i.e. 'the Learned.' A fatal pleurisy stopped Mena's career in 1456 at Torrelazuna, where his friend the Marquis of Santillana erected a sumptuous monument to his memory.

Mena's chief performance, 'El Laberinto,' or 'Las Tre-scintas (coplas),' is a didactic moral poem of the allegorical kind, but the scene is different from that of Dante, and it is unlike the work of the Italian poet also both in metrical form and style. It was published for the first time in 1496.

Quintana, a high authority (*Poesi. Selec. Introduc.*), dwells on it with little of his wonted severity. Stuthey, on the contrary, appears to forget the age in which the poem was written. The scenery, says he, and machinery, are despicable. He has however overlooked its most glowing passages, such as the patriotic end of the naval hero Conde de Niebla: he observes, 'There is no glimpse of imagination, and scarcely a trace of feeling' in it. Even the erudition of the commentator Fernan Nuñez, which must have been prodigious in his time, is mere schoolboys' learning, according to this critic. If Mena, coming 200 years after Berceo, is to be denied the title of the Spanish Ennius, it is much to be regretted that his more fortunate and immediate successors did not estimate his merit, and themselves imitate him in making new words and poetical forms or inflections, which are so congenial to inspiration and originality of thought, and so productive of deep impressions.

Mena also wrote some fugitive pieces; 'La Coronación,' in honour of his patron and friend Santillana, and part of another moral allegory, 'Tratado de Vicios y Virtudes.' His latter was unsuccessfully continued by Gomez Maurique (Petro Guillen) (styled 'el gran trovador,' probably of Segovia), and Jeronimo de Olivaes, Knight of Alcántara. He wrote also 'La Cronica de Juan II.,' from 1420 to 1435. Some old memoirs on noble families of Castile ('Libro de Linages'), and a portion of the Iliad in Spanish, still in MS., are properly attributed to him. This is not the case however either with the first act or the whole of 'La Celestina,' Tragi-Comedia de Calisto y Melibea, which was begun by Rodrigo Cota, and continued in a different style by Fernan de Rojas; nor with the anonymous 'Coplas de Mingo Rebulgo' (a satirical eclogue against Enrique IV., not Juan II., as Bouterwek has hastily fancied); nor the commentary, which, as well as the text, belongs to Fernando del Pulgar, according to Mariana (year 1472 of his history) and the learned Sarmiento ('Obras Postumas'). The primitive sources for Mena's biography are, Bachiller Fernan Gomez de Cibda Real ('Cento Epistolario'), Valero Francisco Romero ('Epicedio a Hernan Nuñez'), and Sanctius Boccensius, the editor of the corrected edition of all his works, which Lucas Junta published at Salamanca in small 12mo. in 1582, and which was the foundation of a 25th, published in 1804 at Madrid, in small Spanish 8vo., by Repulles. This has not however the glosa, or comment, of Fernan Nuñez above mentioned, who is not to be confounded with the chronista Fernan Perez de Guzman.

ME'NAGE, GILLES, was born at Angers (where his father, a man of considerable learning and eloquence, held the office of *Avocat du Roi*), on the 23rd of August, 1613, as he has himself informed us in his 'Anti-Baillet,' chap. 71, where he inveighs with no small bitterness against the malignity of Baillet, who, in his 'Jugemens des Savans,' had made him more than three-years older than he was, forgetting, observes Ménage, that the older I am, the more respect he owes me, and that Callistratus, the jurisconsult, on the fifth law of the Digest, 'De Jure Humanitatis,' has said, 'In our state, old age hath been at all times venerable; for our ancestors were wont to give to old men almost the same honour as to magistrates.' Ménage began life by practising as an advocate at Paris; but finding this profession not to suit his taste or his temper, he got himself made an abbé, which enabled him to hold some livings in the church without cure of souls. He then resided for a time in the family of Cardinal de Retz; but he finally established himself in a house of his own in the cloister of Nôtre Dame, which soon became celebrated for the assemblies of men of letters, whom he continued to gather around him on

the Wednesday evening of every week to the end of his long life,—his *Mercuriales*, as he called them, from the Latin name for that day. A very considerable range of learning, an admirable memory, and some wit enabled Ménage, notwithstanding a pedantry which was often ridiculous, to maintain his position with sufficient éclat as the central figure of these réunions; and he also made some small profession of gallantry, both Madame La Fayette and Madame Sevigné having the honour of ranking him among their avowed admirers. These social enjoyments however did not prevent him from writing a great many books, which brought him a wide reputation, and were highly applauded in his own day by the general voice of the literary world, although the satiric and contemptuous style in which he was apt to indulge had not failed to make him a good many enemies; and one unfortunate performance in particular, his '*Requête des Dictionnaires*,' published in ridicule of the Dictionary of the Academy, for ever shut against him the doors of that institution, or at least excluded him from a seat till he thought himself too old and infirm to accept one when he might have had it. (See the account he himself has given of this affair in his *Anti-Baillet*, chap. 82.) Of his numerous works, the following are the most important:—'*Origines de la Langue Française*,' 4to., Paris, 1650, afterwards enlarged and republished under the title of '*Dictionnaire Etymologique de la Langue Française*,' folio, 1694, and 2 vols. folio, 1750; '*Poemata Latina, Gallica, Græca, et Italica*,' 8vo., Par., 1658, and 12mo., Amstel., 1687; '*Observations sur la Langue Française*,' 12mo., Par., 1672; '*Origini della Lingua Italiana*,' folio, Genev., 1685; '*Anti-Baillet*,' 8vo., Par., 1685, and, along with Baillet's '*Jugemens*,' 4to., Amst., 1725; a valuable edition of Diogenes Laertius, with annotations; and some other editions of classical and other works. After his death, which took place in 1692, his friends published, under the title of '*Ménagiana*,' a collection of his bon-mots and other remarks made in conversation, upon the value of which Bayle, in his Dictionary, has pronounced a very high eulogium, and which is still generally considered to be one of the best, if not the very best, of this class of works. It was originally published in two volumes, the first of which appeared in 1693, the second in 1694; but the best edition is the third, published in 1715, and enlarged by the additions of the learned editor, M. de Monnoye, to four volumes.

MENAI BRIDGE, across the Menai Strait, where it connects Caernarvonshire with the Isle of Anglesey, at the rocky point called Ynys-y-Moch (of Pigs' Island), situated in the latter, is the finest Suspension Bridge hitherto erected, and a noble monument of the scientific skill of the late Thomas Telford. Formerly the passage between Anglesey and the opposite mainland was kept up by six ferries, the chief of which was called Bangor Ferry, from its proximity to that town; but a permanent connection, by means of a bridge, had been in contemplation, and various projects for one had been considered long before the present structure was undertaken. In 1785 a petition for such a bridge was presented to parliament, but the scheme advanced no further until after the union with Ireland, when it was deemed expedient to facilitate the intercourse between the two countries by forming a commodious route to Holyhead. Mr. Rennie, the engineer, was accordingly directed to make plans for the purpose in 1801, and four different designs were made by him, one of which was for a cast-iron arch of 450 feet span, and rising 150 feet above high-water mark. The measure was however postponed until 1810, when it was again resumed, and a committee of the House of Commons for the purpose appointed. Mr. Telford was then instructed to make a survey of the roads from Shrewsbury and Chester to Holyhead, and also to prepare designs for a bridge across the Menai Strait. He made two, adapted to two several points: one at the Swellies, where he proposed a bridge of three cast-iron arches, each 260 feet in span, with a stone arch between each two of them, 100 feet in span; the other at Ynys-y-Moch, with a single cast-iron arch 500 feet in span, to which latter he himself gave the preference. The subject excited much public attention, but great doubts were entertained of the practicability of the plan. In the meanwhile Telford published his design for Runcorn Bridge, with a centre opening 1000 feet wide, and two others of 500 feet each. Upon this he was directed by government to design one on a similar principle, that is, a suspension bridge, for the passage across the Menai.

The site fixed upon by him at Ynys-y-Moch was highly favourable, the opposite shores being bold and rocky, and allowing the roadway of the bridge to be 100 feet above high-water mark. The distance between the supporting pyramids or points of suspension was proposed to be 560 feet, the height of the pyramids 50 above the level of the roadway, the main chains to be 16 in number, with a deflection of 37 feet, their ends being secured in a mass of masonry built over stone arches between each of the supporting piers or pyramids and the adjoining shore, and these arches, four on the Anglesey and three on the Caernarvonshire side, being each 50 feet in span. The roadway is divided into two carriage ways, each 12 feet wide, with a footpath 4 feet wide between them.

The plan having been approved of by parliament, the sum of 25,000*l.* was voted to enable the commissioners to commence operations. Accordingly, in July, 1815, all the requisite preparatory steps were taken, labourers were engaged, workshops built, and the levelling for the foundations commenced, when such opposition was made to the scheme that the commissioners were obliged to apply to parliament for an act to confirm and amend their powers. Although this occasioned considerable delay, all the preparatory works continued to be proceeded with. The new bill received the royal assent, July 2, 1819, and the first stone was laid on the 10th August following. The three arches on the Caernarvonshire side were keyed in on January 18, February 27, and March 25, 1822; those on the Anglesey side, August 31, September 14, and October 3 and 24 of the same year. In March of the following year the iron-work for the attachment of the main chains to the rock was begun to be fixed; and in July a new act of parliament was passed, conferring greater authority on the commissioners; besides which the Treasury issued 108,498*l.* for completing the bridge and paying the sum awarded by the jury for the purchase of Bangor Ferry. In 1824 the works were so far advanced, that the only remaining difficulty was, 'How are the main chains to be put up?' a question that gave rise to much speculation and doubt, for no precise details had been determined upon up to that time, which was so far an advantage, that the engineer had the benefit of full consideration and experience, and many mistakes were obviated that must have happened had the details been all settled beforehand.

In the beginning of May the cast-iron segments and saddles were carried up to the pyramids; but it was not till the April of the year 1825 that the first chain was fixed, which operation was then most satisfactorily accomplished. After the second chain had been put up, it was found necessary to replace some of the bars which had been damaged; and owing to this it was practically ascertained that if one or more links of a chain should at any time be injured, they could be taken out and replaced. On the 9th of July the last chain was fixed, and by the end of August the whole of the suspended parts of the chains had been connected with each other; and on the 2nd September the suspending of the roadway-bearers was commenced. In January, 1826, preparations were made for opening the bridge, and on Monday the 30th the mails drove over it for the first time. Shortly after however (February 6) a tremendous gale did considerable damage to the iron-work, and repeated gales during the spring tended greatly to retard the necessary operations in repairs. But no inconvenience has been since felt; and there is reason to believe that, with ordinary care and attention, this noble structure will last for ages.

With respect to the constructive details and operations of the work, those who wish for such information will find all the particulars in a large folio by W. Alexander Provis, the superintending engineer, entitled, '*An Historical and Descriptive Account of the Suspension Bridge over the Menai Strait in North Wales*,' &c., London, 1828.

All that we add is the following (as given by Drewry in his work on suspension bridges):

The weight of the 16 main chains between the points of support, including connecting plates, screw-pins, wedges, &c., is

	Tons.	cwt.	qrs.	lbs.
The transverse ties	394	5	0	16
The suspending-rods and platform, &c.	245	13	2	27

Making the total suspended weight 643 . 15 2
N 2

According to Mr. Rhodes's experiment the tension on the iron at each point of suspension is 1.7 times the whole suspended weight, or 109.4.42 tons. The entire section of the bars of the chains is 260 square inches, which would bear 7020 tons without breaking; or taking the standard of 9 tons per square inch, the chains will bear without any risk ($9 \times 260 =$) 2340 tons, or $2340 - 109.4.42 = 1245.5$ tons more than the strain produced by the weight of the bridge

itself; consequently it may safely be loaded with $\frac{1245.5}{1.7}$ or 732.1 tons, besides its own weight.

MENANDER (*Μένανδρος*), a Greek comic poet, one of that class who are called the writers of the new comedy, was born B.C. 341, and died, as some suppose, by drowning, B.C. 289 or 290. According to Suidas he was the son of Diopithes and Hegistraté, was cross-eyed, and yet clear-headed enough.* The same authority says that he was inordinately addicted to women. He wrote more than one hundred comedies, of which only fragments remain, but in spite of this fertility, and although the most admired writer of his time, he was only eight times victor. His master was Theophrastus, according to the testimony of Hemphila.

All antiquity agrees in praise of Menander. We learn from Ovid that his plots all turned on love, and that in his time the plays of Menander were common children's books—

* *Fabula jucunda nulla est sine amore Menandri,
Et solet hic pueris virginibusque legi.*
Ovid, *Trist.*, ii. 70.

Julius Cæsar called Terence a 'dimidiatus Menander,' having reference to his professed imitation of the Athenian dramatist. Plutarch preferred him to Aristophanes, and Dion Chrysostomus to all the writers of the old comedy. Quintilian (*Inst. Orat.*, x., l. 69) gives him unqualified praise as a delineator of manners. From these notices, from the plays of Terence, and from an awkward compliment passed upon him by Aristophanes the grammarian, we may infer Menander to have been an admirable painter of real life. His effeminate and immoral habits, and that carelessness in his verses, which subjected him to the charge of plagiarism, or at least of copying, all point to the man of fashion rather than the imaginative poet. And indeed the writer of what is termed the new comedy (that, namely, which satirised characters, not persons) had more occasion for knowledge of the world than for higher qualities, just as the fashionable novel-writer of the present age had much better be a nobleman or a member of parliament than a philosopher or a speculative thinker. It has been observed that there is very little of the humorous in the fragments of Menander which remain; but we cannot judge of a play by fragments. Sheridan's plays, if reduced to the same state, would be open to a similar charge, although he is perhaps the most witty writer of any age or country. The essential aim of the comedy of manners is to excite interest and smiles, not laughter.

The plays of Menander were probably very simple in the dramatic action. Terence did not keep to this simplicity, but, as he tells us himself, he added to the main plot some subordinate one taken from a different piece of Menander; thus, as he says, making one piece out of two.

Between the time of Aristophanes and that of Menander a great change must have taken place in the Athenian character, which was probably mainly brought about by the change in the political condition of the Athenian state. The spirit of the people had declined from the noble patriotism which characterised the plays of Aristophanes at a time when Athens was struggling for supremacy in Greece; and in the time of Menander, Macedonian influence had nearly extinguished the spirit that once animated the conquerors of Marathon and Plataea. Manners probably had not changed for the better in Athens, though the obscenity and ribaldry of Aristophanes would no longer have been tolerated. The transition from coarseness of expression to a decent propriety of language marks the history of literature in every country. Thus the personal satire and the coarseness which characterised the old comedy were no longer adapted to the age and circumstances in which Menander lived, and there remained nothing for him to attempt as a dramatist, but the new species of comedy in which, by the unanimous judgment of all antiquity, he attained the highest excellence.

The fragments of Menander are principally preserved in

* *Στραβὸς τὰς ὕψας δέξας δὲ τὸν νοῦν.*

Athenæus, Stobæus, and the Greek lexicographers and grammarians. A good critical edition of the fragments of Menander and Philemon, by Meineke, was published at Berlin 1823, 8vo. It seems possible that some of the plays of Menander may yet exist; at least there is evidence to the fact of some of the plays having been in existence in the seventeenth century. (*Journal of Education*, i. 188.)

Many of the fragments of Menander have been well translated by Cumberland in the 'Observer.' (Suidas, ed. Gaisford, p. 2453; Fabr., *Bibl. Gr.*, vol. iii. p. 455, ed. Hailes; *Encycl. Metropolitana*.)

MENANDER PROTECTOR, a Greek writer, who lived at Constantinople during the latter half of the sixth century. He was one of the emperor's body-guards, whence he derived the surname of Protector. (*Cod. Theodos.*, vi. 24.) He wrote a history of the Eastern empire from A.D. 559 to A.D. 582, in eight books, of which considerable extracts have been preserved in the 'Eclogæ Legationum,' attributed to Constantine Porphyrogenetus. The best edition of Menander is by Bekker and Niebuhr, Bonn, 1830, together with the fragments of Dexippus, Eunapius, Patricius, &c.

MENASSEH BEN ISRAEL, a celebrated Jewish Rabbi, was born in Spain about A.D. 1604. He was educated in Holland, whither his father, Joseph Ben Israel, had fled to escape the persecution of the Inquisition. At the age of eighteen he succeeded his tutor, Rabbi Isaac Usic, as preacher and expounder of the Talmud in the synagogue at Amsterdam; and he soon after commenced his work entitled 'Conciliador,' on which his reputation as one of the most learned and accurate of Jewish theologians chiefly rests.

At the age of thirty-five he lost his fortune through the confiscation of his father's property by the Spanish Inquisition; and in consequence of this loss he betook himself to commerce, a necessity of which he grievously complained on account of the interference which it caused to his studies. He came over to England during the Protectorate, and was graciously received by Cromwell, from whom he obtained some favours for his nation. He died at Amsterdam about 1659.

Menasseh lived on terms of intimacy with several of the most learned men of his age, by whom he was highly esteemed for his erudition and moral worth. Grotius testified his respect for the Rabbi's learning by consulting him on the most difficult points of theology, and by recommending his works, especially the 'Conciliador,' to the attention of biblical students. Menasseh was strongly attached to Judaism, and some of his works are disfigured by the introduction of invectives against Jesus Christ.

The following are his chief works:—

1, 'Conciliador nel Pentateucho,' published in Spanish at Amsterdam in 1632. A Latin translation of this work, by Dionysius Voss, was published at Frankfort in 1633, with the title, 'Conciliator, sive de Convenientia Locorum S. Scripturæ quæ pugnare inter se videntur.' 2, 'De Resurrectione Mortuorum,' Amst., 1636. 3, 'De Creatione Problemata xxx,' Amst., 1635. 4, 'De Termino Vitæ Libri iii,' Amst., 1639. 5, 'Spes Israelis,' and in Spanish, 'Esperanza de Israel,' Lond., 1650. 6, 'A Defence of the Jews in England,' Lond., 1656. 7, An edition of the Hebrew Bible, in 2 vols. 4to., Amst., 1635.

MENDELSSOHN, MOSES, was born at Dessau, in 1729, where his father Mendel was a schoolmaster. Being a Jew, he instructed his son in the Hebrew language and the elements of Jewish learning, though he caused him to be instructed in the Talmud by others. The celebrated work of Maimonides, 'Moreh Nevochim' (the guide to the wanderers), he studied with such zeal that an impaired constitution and a distorted spine were lasting marks of his application. This work however seems to have strengthened his mental powers. In 1742 he went to Berlin, where he subsisted on the small bounties of the members of his own persuasion; but his mind was greatly improved by his intercourse with men of superior intellect. Israel Moses, a Jewish mathematician, urged him to read Euclid's 'Elements'; a physician named Kitsch instructed him in Latin; and by the aid of Dr. Aaron Salomon Gumpertz, he became acquainted with modern literature. He lived for some time in a very humble condition, until a rich silk-manufacturer, named Bernard, took him into his house as instructor to his children. He subsequently became a superintendent in the factory, and was ultimately taken into

partnership. His intimacy with Lessing began in 1754, and is said to have been of the greatest advantage to him. Philosophy now became his favourite study, and his first work was his 'Briefe über die Empfindungen' (letters on the sensations). He published other philosophical works from time to time, and gained a high reputation for acuteness, rather than for originality of thought: his excellent moral character also greatly contributed to the respect in which his religious authority was held. His 'Jerusalem, oder über Religiöse Macht und Judenthum' (Jerusalem, or an essay on the interference of the state in matters of religion and Judaism) appeared in 1783. He had begun a philosophical work entitled 'Morgenstunden' (morning hours), of which the first volume was published, when he received Jacobi's 'Essay on the Doctrine of Spinoza.' He thought that this essay charged his friend Lessing (the deceased) with Spinozism; a charge then much more heavy than at present, when many German philosophers are avowed admirers of Spinoza. The zeal with which he defended his friend by a written answer excited him to such a degree, that a cold, which he subsequently took, was sufficient to terminate his existence in 1786.

As an instance of the successful pursuit of knowledge under difficulties, Mendelssohn is immortalised; and to do him full justice, the circumstances of his life must be remembered by the reader of his works, one of which has been translated into almost every European language: this is his 'Phædon,' a dialogue on the immortality of the soul, held between Socrates and his disciples. The characters are taken from Plato's dialogue of the same name, and the descriptive parts are mere translations of the original. The Jewish philosopher however has made Socrates produce new arguments in place of those attributed to him by his disciple Plato; thinking these new arguments better adapted to the conviction of modern readers. The following is his principal and indeed his only argument, the rest of the dialogue being employed in its defence, and in expressions of reliance on the goodness of the Deity. For ~~the~~ ^{the} three things are required: first, a state of the changeable thing prior to its change; secondly, the state that follows the change; and thirdly, a middle state, as change does not take place at once, but by degrees. Between being and not-being there is no middle state. Now the soul being simple, and not, as a compound body, capable of resolution into parts, must, if it perish, be absolutely annihilated; and in its change from death to life, it must pass at once from being to not-being, without of course going through any middle state; a change which, according to the three requisitions of change, is impossible. Thus by *reductio ad absurdum* the immortality of the soul was proved. Kant, in his 'Critik der reinen Vernunft' (second edition*), has shown the futility of Mendelssohn's argument, while he admits his acuteness in perceiving that mere incapability of resolution into parts was of itself not sufficient to preserve the immortality of the soul, as had been supposed by many philosophers of the time. Mendelssohn, by assuming that change must be gradual and not sudden, thought that he had established his point, as the soul, being simple, could not admit of gradual resolution. Kant however shows that we may conceive a gradual annihilation even without resolution into parts; or, to use his own expression, a diminution of the *intensive magnitude*. Thus a deep red colour may grow fainter and fainter till at last all the redness is gone, and this without any diminution of the surface coloured. Another fallacy in Mendelssohn's argument is that his definition of change applies only to a transition from one state of being to another, and therefore does not include a transition from being to not-being. For if not-being be considered a state of being, there is no occasion for an argument at all, as the continuance of being is assumed in the definition of change, nor would anything be gained by supposing the soul in such a paradoxical state as nonentity with still a sort of being attached to it.

A magnificent edition of Mendelssohn's works was published lately at Berlin: an English version of the 'Phædon' appeared in 1789 and also in 1838.

MENDE. [LOZKE.]

MENDICITY. [PAUPERISM.]

MENDIP HILLS, a long ridge of limestone extending

from Wells in Somersetshire to the Bristol Channel at Bleydon Hill and Brean Down. Through its whole length it is what geologists term an anticlinal axis, the strata dipping to the north, under the drainage of the Avon and the Yeo, and to the south under the low plains watered by the Axe and the Brue. This axis passes from Frome by the Beacon Hill above Shepton Mallet, Mashury Castle, Nine-Barrow Hill, and Black Down, to Bleydon Hill, Uphill, and Brean Down, from whence, according to Buckland and Conybeare, it may be supposed to be continued into the Steep Holm in the Bristol Channel.

Along the line of the axis of Mendip old red-sandstone strata show themselves for considerable lengths, and form the nucleus of this miniature mountain-range. They are exposed on the roads from Wells to Chewton Mendip, and to Harptree, in each case evidently lying below the carboniferous limestone. Upon the slopes of this limestone, both north and south, rest considerable stratified masses of what is often justly termed magnesian conglomerate, and this is covered by the general mass of red marls which fill so large a tract in the low parts of Somersetshire. The limestone series is estimated by Buckland and Conybeare at from 500 to 1000 yards thick. The axis of the Mendip Hills runs irregularly east and west: the geological era of its principal upward movement appears to be anterior to the red marls, and probably to the red conglomerate; though near Wells, and in other parts the slope of the conglomerate beds proves a subsequent movement. There is no better example known of the unconformity of strata than that presented in Vallus Bottom, near Wells, by the junction of the lower oolite formation and the mountain or carboniferous limestone. Here the upturned and almost vertical strata of mountain-limestone are found covered by horizontal strata of oolite, each of these contrasted rocks containing the characteristic fossils which belong to them elsewhere. What renders the case more curious is the fact that the level surface of the subjacent ~~mass~~ ^{beds} of limestone is not only worn smooth by littoral action below the oolite, but also covered by attached oysters, and perforated by the lithophagous shells of the oolitic sea into large and small holes now full of the oolite, and partly retaining the boring shells not uncommon in that rock.

o, the oolite in level beds; l, the mountain limestone in steeply inclined beds.

The most elevated point of the Mendip Hills is Mashury Castle, about 999 feet above the sea-level.

The features of these hills remind the observer of some parts of northern Derbyshire, both in the wide bare surface of limestone and the rugged glens which suddenly break the dullness of the open country. These narrow valleys appear like cracks and fissures in the mass of calcareous rocks, which, in Cheddar Cliffs, rise 285 feet perpendicularly from the feet of the spectator, and undoubtedly exceed in grandeur the noblest rocks of Derbyshire or Yorkshire. Several of these glens are called 'combes,' and Brockley Combe may be taken as a beautiful example of the mixture of gray rock and ancient wood.

From the chasms just alluded to the transition is easy to the caves and internal fissures, which are numerous in Mendip. Many of these have become familiar to geologists by the uncommon abundance of bones found in them by a host of explorers since the days of Catcott, the celebrated and unfortunate explorer of Hutton Hole.

Dr. Buckland, in his 'Reliquiæ Diluvianæ,' describes, from the notes of Mr. Catcott and Mr. Conybeare, the circumstances under which the teeth and bones of elephants, horses, oxen, stag, bear, fox, and other animals of the 'Mastozootic' era occurred at Hutton. The bones were found in the ochre-pits, which were antiently worked; they were mostly white, well preserved, and appear to have been drifted in by water, or collected from the falling in of quadrupeds roaming on the surface.

* Not in the first edition. The complete edition of Kant's works, now publishing by M. Rosenkranz, at Leipzig, is highly valuable, as distinguishing the additions made in subsequent editions to the original form.

At Buringdon, in the Mendip Hills, and also in Wokey Hole, a celebrated cavern near Wells, human bones have been found of high antiquity, but being accompanied by urns or other marks of sepulture, it is not supposed they belong to races contemporary with the mammoth and large cavern bear. The specimens of this latter animal in the cave at Hutton are of enormous bulk.

Not far from Hutton Hole is the no less renowned cavern of Banwell, explored under the direction of the bishop of Bath and Wells. The best collection of the contents of this rich repository is to be seen near the mouth of the cave, at the house of Mr. Beard. The compacted parts of this cavern are accessible by steps made in the rock, and are much visited. The bones belong chiefly to oxen and deer. Bones of elephants, bears, and other carnivora occur less commonly. The specimens are usually in admirable preservation, and contrast remarkably with the fragmentary bones of the same animals at Kent's Hole and Kirkdale.

Very recently Mr. Long communicated to the British Association at Newcastle a notice of human bones found in a cave at Cheddar.

The Mendip Hills, in their metalliferous products, resemble the similarly constituted mountains of Derbyshire and Flintshire. They yield galena, calamine (carbonate of zinc), and ochre. Manganese is dug about East Harptree. The galena occurs principally in limestone; the calamine belongs to the overlying magnesian conglomerate. In that rock agates occur, and the large geodic crystallizations of quartz called 'potatoe-stones.' The fossil corals, shells, trilobites, &c. of the Mendip Hills have been long known to collectors; but a complete account of them, as we believe, never been prepared.

(Conybeare and Phillips, *Geology of England and Wales*; Buckland and Conybeare, 'On the South-west Coal District of England,' in *Geol. Trans.*, vol. i., new series.)

MENDOCINO, CAPE. [CALIFORNIA.]

MENDOZA, INIGO LOPEZ, better known as the Marquis de Santillana (Sancta Juliana), was born in 1398, at Carrion de los Condes, and died in 1458. He was grandson of the poet Pero Gonzalez Mendoza, and a descendant of that Mendoza, who, in the battle of Aljubarrota, saved the life of Juan I. at the expense of his own. (Romane de Hurtado de Velarte: 'El Caballo vos han muerto'.) He was also the father of the first duke of Infantado, who secured the preservation of his valuable library and directed it to be kept at his palace of Guadalajara.

Santillana was the most elegant scholar at the court of Juan II., then the most brilliant in Europe. Much of his poetry is still in MS., and is partly lost or lying in dust. Several of his pieces, however, chiefly devotional and amatory, are contained in the older Cancioneros. Like the compositions of D. Juan Manuel, the marquis Enrique de Villena, and many others, they exhibit a singular contrast with the fierceness of that period. They throw a false shade, perhaps a decent veil, over realities too disgraceful and disgusting, from which the gifted few sought mental relief in subtlety and imaginary affection; but such poetry can never touch the heart nor even be forcibly expressed when it is not genuine, that is to say, when it is not deeply felt. By introducing the sonnet, Santillana (Quintana's *Poes. Escog.*), became a forerunner of the bold innovator Boscan. But he did more, by endeavouring to impart a moral tendency to the national poetry, by extending it by allegorical invention, and embellishing it with learning. His efforts in that respect are apparent in his 'Elegy to his tutor and friend Villena,' and his 'Doctrinal de Provados,' which show that he was no adherent of Alvaro de Luna. All parties were eager to obtain the powerful assistance of Santillana's military, political, and moral character. His 'Refranes' (traditional proverbs) were reprinted by the learned Mayans (*Origenes de la Lengua Castellana*, vol. i., p. 179.)

Fernando del Pulgar, Sarmiento (*Obras Postumas*), Nico. Antonio, and Sanchez (*Colec. de Poes.*), give much curious information on this Mendoza.

MENDOZA, DIEGO HURTA'DO, a scholar, statesman, and general under Charles V., was grandson of the above Mendoza, and younger son of the first marquis of Mondejar, who was also second count of Tendilla. He was born in 1503, at Granada, and not at Toledo, as was supposed by Tamayo Vargas. He received his early education at home from Peter Martyr d'Angleria, who had been brought to Spain by the first count of Tendilla to teach the

youth of the nobility. After learning Arabic at Granada, he studied Latin, Greek, Hebrew, divinity, and civil and canon law at Salamanca, where, by way of relaxation, he produced the first specimen of the comic romance, in his 'Lazarillo de Tormes,' a work which has been improperly ascribed by Siguenza to the Jeronymite Juan Ortega. It is written in that *gusto picaresco*, which was much in fashion in the seventeenth century. Being sent from the university to the Imperial army in Italy, to show his talents in a new capacity, he still found time occasionally to visit the universities of that country, and to hear the eminent lecturers, such as Niphus of Naples and Montesdoca of Seville. In his capacity of ambassador at Venice and at Trent, where political interests were at stake; at Rome, the centre of intrigue; and as general in Tuscany, which was threatened by the Turks and their ally Francis I., he always defeated the treachery of the French king, and baffled the designs of all parties. He faced every danger, and commanded the respect and admiration even of those whom he could not please. (Paul. Mann., *Cic. de Philoso.*, Lazaro Bonamico.) Nor could he conceal that spirit of freedom which Charles had destroyed in Spain. He strongly reprobated his sale of the Tuscan fortresses to Cosmo de' Medici, and by his opposition prevented his transfer of Milan and Siena to Paul III., who wanted to buy them for Octavio Farnesio. In a letter to Zuñiga, alluding to ambassadors, he boldly says, 'When kings wish to cheat, they begin by us.' The republicans or burgesses indeed looked on Mendoza as the greatest enemy of Italy. That country however was indebted to him for having introduced into it the writings of Basil the Great, Gregory of Nazianzus, Cyril of Alexandria, Archimedes, Appian, and others. Not satisfied with employing Arnoldus Ardenius in transcribing the Greek MSS. of different libraries, especially those which Cardinal Bessarion had bequeathed to Venice, Mendoza sent Nicolaus Sophianus to Thessaly and Mount Athos in search of manuscripts. He also paid a heavy ransom for a Turkish prisoner who was a favourite of Solyma, the Magnificent. As a return for this service he received ancient works from the sultan, to whom they were useless, and begged him to permit the Venetians, then in great want of corn, to import it from Turkey. His request was granted, with a present of several chests of literary treasure. In 1555 Mendoza was superseded at Rome, in order to propitiate Julius III. Subsequently he fell under the displeasure of that heartless bigot Philip II., who banished from his court this old servant, then sixty-four years of age. This act of royal severity proved however beneficial both to the illustrious veteran and to posterity. In his retirement at Granada Mendoza prosecuted those studies which were congenial to his taste: he investigated antiquities, collected above 400 Arabic MSS., and crowned his literary fame by his 'Guerra contra los Moriscos,' the publication of which, even with omissions, the government did not permit till the year 1610. The true text was restored in 1776, at Valencia, by Portalegre, who prefixed to it the author's life, which, although ill written, is highly interesting. In this work, the finest specimen of the historical style in the Spanish language, Mendoza has left the best example of an imitation of the Latin historians that modern European literature possesses. The rich and florid diction of this history forms a contrast with the conciseness and rigidity of Sallust, with whom however Mendoza has generally been compared. The modern historian is a model of impartiality: he does not even spare his own brother. Having been an eye-witness of most of the events which he has so admirably recorded, he has happily combined in the same work the strictest accuracy with integrity and the ability of a great writer.

In 1575 Mendoza obtained permission to return to Madrid on business, but he died shortly after his arrival there. He bequeathed his valuable library to the king. Ambrosio Morales, Nico. Antonio, Bonterwek, and many others, are profuse in their eulogiums of Mendoza. Juan Diaz published his poems in 1610 at Madrid, but without the numerous comic and satiric pieces. Other more important works of his have never yet been published: among them are his political commentaries.

MENDOZA. [PLATA, LA.]

MENEHOULD, SAINTE. [MARNE.]

MENELA'US (called also MILLEUS by Apian and Mersenne, but on what authority is not known; in a copy of Weidler which belonged to Montucla we find the latter, in a manuscript note, describing Milleus as 'Menelaus

défiguré par les Arabes') was an Alexandrian, who observed the stars for a long while at Rome, and was living there in the time of Trajan. He is mentioned by Proclus and Pappus, and probably is the person intended by Plutarch, who mentions a mathematician of that name. Pappus gives the titles, or other mention, of at least two works of Menelaus which have not come down to us. Ptolemy, in the *Syntaxis*, compares some of his own observations with those of Menelaus.

The only writing of Menelaus which has come down to us is the Latin treatise on spherical geometry, translated from the Arabic; the Greek is probably lost. This work, in three books, was published (Lalande) in a collection of Greek geometers made at Paris, in 1626; and afterwards (Lalande, Heilbronner) by Mersenne, in his *Universæ Geometriæ Synopsis*, Paris, 1644; also (Heilbronner and Weidler) by Regiomontanus. Another work on chords is said by Heilbronner to be contained in Mersenne's *Synopsis*: this is a mistake, since the work is entirely lost.

The books of Menelaus on spherical geometry have been much used by Ptolemy in the *Syntaxis*, and the latter had for a long time the credit of two very remarkable propositions which appear in Menelaus, and which have been much used by Carnot and others in the modern extensions of geometry. These are the well known propositions relating to a transversal which cuts the three sides of a triangle, plane or spherical. [TRIANGLE.] There are other propositions of great ingenuity; so that Menelaus, who must be looked on as the successor of Hipparchus and Theodosius in the school of Greek geometers who treated of the doctrine of the sphere, must also be considered as having gone considerably beyond his predecessors.

MENES. [EGYPT.]

MENGES, ANTON RAFAEL, one of the most distinguished artists of the eighteenth century, was born at Aussig in Bohemia, in 1728. He was only six years old when his father, who was himself a painter, though one of very moderate talents, determined to bring him up to the same profession, whether he had talent or not, adopted a course of education for him more calculated to inspire him with a disgust than with a true relish for it. Being of a most harsh and tyrannical disposition, he compelled the boy to employ himself in drawing the whole day long, allowing him neither recreation nor relaxation from his tasks. In course of time Rafael was instructed by his father in oil painting, and miniature and enamel painting, but was still tasked in the same rigorous manner, and frequently received severe chastisement, if he had completed not within the time allotted him—which was generally short enough—what he had been set to do. In 1741 his father quitted Dresden, whither he had been called by Augustus III. (for he was a native of Denmark), and went to Rome, taking young Menges with him. On his arrival in that city, his father used to take him every morning to the Vatican, in order that he might there study the productions of Raffaele, and would make him remain there the whole day, without other refreshment than a bottle of water and piece of bread, until he came to fetch him back in the evening; nor was he even then allowed to recruit himself from his fatigue, but compelled to revise and finish up the studies he had brought home. This excessive drudgery did not however disgust him with the profession to which he was thus in a manner yoked: still the mode of life it occasioned was prejudicial, inasmuch as it prevented his acquiring other knowledge, and tended to render him shy of all society. In 1744 he returned with his father to Dresden, where his talents obtained for him the notice of Augustus, who appointed him court-painter; but according to a stipulation he had previously made, he was permitted to return to Rome, and his father accompanied him. After continuing his studies some time longer, he began to distinguish himself by his original compositions, among the rest by a Holy Family, in which the Virgin was painted from a beautiful peasant girl, of whom he became so enamoured, that he turned Catholic for her sake and married her. After that event he again returned to Dresden, where his pension was raised to a thousand dollars, and he was commissioned by the king to paint a large altar for a new chapel; which he wished to execute at Rome. But on his arrival there, other commissions (among which was a copy of Raffaele's 'School of Athens' for Lord Percy, afterwards duke of Northumberland), and the Seven Years War, which caused the stop-

page of his pension, interfered with the prosecution of the work. In 1757 he made his first attempt in fresco, a ceiling-piece in St. Eusebio, which was in too simple a style to satisfy the taste of that day. His 'Apollo and the Muses,' another work of the same class, in the Villa Albani, obtained for him much greater renown, and is one that will bear comparison with those by the greatest Italian masters. About this time he became acquainted with Webb, to whom he communicated his ideas on art, which the other passed off as his own in his 'Remarks on Poetry and Painting.' Menges's reputation was greatly increased by the numerous works he executed for Charles III. of Spain, by whom he was invited to Madrid in 1761, and remained in that country till 1773, with the exception of an interim of three years, in the course of which he painted the ceiling of the Camera de' Papi at Rome. His pencil was employed in decorating the royal palaces of Spain; and the Apotheosis of Trajan, in that of Madrid, is considered his chief d'œuvre.

After a marriage of the utmost domestic harmony, Menges lost his wife in 1778. From that time his health began to decline, nor was it long before he followed her to the tomb: he died on the 29th of June in the following year, and was buried by her side in the church of San Michele Grande at Rome. Notwithstanding the great sums he had received during his life, about 250,000 livres, instead of amassing money, he left scarcely sufficient to defray the expenses of his funeral; but the king of Spain bestowed pensions on his two sons, and provided also for his five daughters. Although Menges's reputation as an artist does not now stand so high as in the last century, he undoubtedly possessed many excellences, and, compared with his immediate contemporaries, deserved the applause showered upon him. Refined taste, nobleness of ideas, correctness of drawing, vigour of colouring, finished execution, and studied grace are merits of a high rank, which he possessed in an eminent degree; but though most carefully studied, and in conformity with the principles he laid down for the art, his works do not always display those loftier qualities of mind which the higher branch of historical painting demands. His writings, which were published after his death by the Cavalier d'Azara, contain many excellent precepts, and both practical and critical observations, and have accordingly been translated into the principal modern languages.

MENIN, or MEENEN, a fortified town in West Flanders, situated on the left bank of the river Iys, by which it is separated from France. It is 11 miles north from Lille, and 30 miles south from Bruges, in 50° 48' N. lat. and 3° 12' E. long.

Menin contains manufactures of linen, lace, and soap, besides many breweries, salt-refineries, and oil-mills. It also carries on a considerable trade in horses, cattle, sheep, corn, and tobacco. It has a population of 7909 inhabitants.

MENISCUS. [LENS.]

MENISPERMA'CEÆ are an important and extensive natural order of Exogenous plants, considered by some to be Polypetalous, and referred to De Candolle's Thalamifloral subclass; by others placed among the Monochlamydeæ of that author. The order consists of twining or scrambling shrubby plants, with alternate leaves without stipules, and small greenish or white unisexual flowers, often collected in large loose panicles or racemes. The floral envelopes are arranged in a power of three or four, and usually in more rows than one; whence arises the opinion that these plants belong to Polypetalous Exogens, the inner series being regarded as a corolla. The stamens are either distinct or monadelphous, either equal in number to the inner series of the calyx, and of the same number, or much more numerous. The carpels are in most cases three, or some multiple of that number, either distinct from each other or consolidated. The fruit consists of succulent one celled drupes, with a solitary seed, and a horseshoe shaped embryo, with thin flat cotyledons.

The wood of the stem is arranged essentially upon the Exogenous plan, but has some striking peculiarities. According to M. Decaisne, it has no annual concentric layers. The woody plates are always simple, and do not divide longitudinally, as in other Dicotyledons, but increase each year by the formation of a new woody layer outside the former and inside the liber. The latter ceases to grow after the first year. In Cissampelos Pareira and some others new woody plates, like the first in appearance, but having no spiral vessels or liber, show themselves, at the end of several years, on the outside of the first, and produce around them a concen-

tric circle, a formation which may be repeated a great many times. (*Comptes Rendus*, v. 393.)

Menispermaceæ are usually bitter and tonic plants; the species of *Cocculus* called *Bakis*, *Fibraurea*, *cinerascens*, and others, are used in their native countries as a remedy for intermittent fevers. *Cocculus palmatus* furnishes the Calumba root of the shops, a valuable bitter. *Pereiria medica* is used for the same reason in Ceylon, as is *Clypea Burmanni* in Malabar, and various sorts of *Cassampelos* in Brazil. But the bitter principle, which in its diluted state is thus valuable, becomes a dangerous poison, if concentrated, as in the seeds of *Anamirta Cocculus*, the *Cocculus Indicus* of the shops.

Menispermum canadense.

1, a male flower; 2, a female; 3, the ripe fruit; 4, a vertical section of the same, showing the embryo and horse shoe seed.

MENISPERMINA, a vegetable alkali extracted by Pelletier and Couerbe from the *menispermum cocculus*, or *cocculus Indicus*, in the shells of the fruit of which it occurs.

MENISPERMUM (so called from *μήνη*, the moon, and *σπέρμα*, seed, from the crescent-like form of its fruit), a genus of the natural family of *Menispermaceæ*, which formerly contained numerous species, many of them valuable for their medicinal and other qualities, such as the Calumba root; and the berries called *Cocculus Indicus*, which are now referred to the genus *Cocculus*. *Menispermum*, as at present constituted, contains but few species; and these are climbing shrubs which have their sepals and petals in quaternary order, arranged in two or three whorls. *Male*, stamens 16 to 20; *Female*, ovaries 2 to 4; Drupes baccate, round, kidney-shaped, single-seeded. *M. canadensis* and *emilacinum* are found in the United States of America, and *M. Dauricum* in the wooded hills of Dauria.

MENNONITES, a religious sect which sprung up in Holland and Germany about the time of the Reformation, and which is identified by many writers with the sect of the Anabaptists, with whom the Mennonites held several leading doctrines in common. [ANABAPTISTS.] They received their appellation from Simon Menno, who was born at Witmarsum, a village in Friesland, in the year 1505. In 1536 he left the Roman Catholic church, in which he was a priest, and joined the Anabaptists, among whom he became a teacher in the next year. During the remainder of his life, Menno travelled with his family and preached his doctrines throughout a great part of Germany and Holland, where he gained many proselytes, chiefly from among the Anabaptists. He died in the year 1561, in the duchy of Holstein. His works were published in one volume folio, at Amsterdam, in 1651. Though he is said to have been a notorious profligate when young, his character after he

came forward as a religious teacher was unimpeachable; and he was possessed of considerable genius, some learning, and a persuasive eloquence. His doctrines were free from the anti-social and licentious tenets and the pretensions to inspiration which are ascribed to the Anabaptists; but he agreed with them in condemning the baptism of infants, in expecting a personal reign of Christ on earth for a thousand years at the Millennium, in excluding magistrates from the Christian church, and in maintaining that all war was unlawful, that the taking of oaths was prohibited by Christ, and that human science is useless and pernicious to a Christian. But these tenets were so explained and modified by Menno, as to differ very little from the doctrines generally held by the reformed churches. He insisted upon the strictest attention to moral duties, and exercised a most severe discipline upon offenders.

The followers of Menno very soon split into two sects, the Flemings and the Waterlandians, so called from the countries in which they arose. The latter somewhat relaxed the severe discipline of Menno towards offending members, which the former maintained in all its rigour. The Flemings divided again, on the subject of the treatment of excommunicated persons, into Flandrians and Frieslandians, and there also arose a third division called Germans. In process of time the greater part of these sects joined the Waterlandians.

The Mennonites put forth several confessions in the seventeenth century, the earliest of which is one drawn up by the Waterlandians. By these confessions it appears that their doctrines were nearly the same with those mentioned above as held by Menno. According to Mosheim, their fundamental principle was that 'the kingdom which Christ established upon earth is a visible church or community, into which the holy and the just are alone to be admitted, and which is consequently exempt from all those institutions, and all those regulations that have been invented by human wisdom for the correction and reformation of the wicked.'

In the seventeenth century the Mennonites obtained toleration in Holland, Germany, and England. In the year 1630, a considerable part of them arranged their differences in a conference at Amsterdam, and formed a union, which was renewed in 1649.

Further information respecting this sect may be found in Herman Schyn's *Historia Mennonitarum plenior Descriptio*, which is a defence of the Mennonites, and in which the author protests against their being confounded with the Anabaptists; and also in Mosheim's *Eccles. Hist.*, cent. xvi., sect. iii., part ii., c. 3; and cent. xvii., sect. ii., part ii., c. 5. It is to be wished that Mosheim had written the history of this sect in a spirit of greater candour.

MENOBANCHUS. [NECTURUS.]

MENOPO'MA. [SALAMANDRUS.]

MENORCA, or **MINORCA**, is the second in size ('the minor') of the Balearic Islands. It is situated in the Mediterranean, off the eastern coast of Spain, between 39° 47' and 40° 5' N. lat., and between 3° 50' and 4° 23' E. long. It lies 24 miles to the east-north-east of Mallorca, about 125 miles south-east of the coast of Cataluña, 162 miles east by south from the mouth of the Ebro, the nearest part of Valencia, and about 190 miles north from the territory of Algiers in Africa. It has a circumference of 62 miles, and an area of about 300 square miles. In form it is irregular; being in length 33 miles, and in the broadest part 13 miles. The coast is indented on every side with small bays or deep creeks, and is surrounded with islets, rocks, and shoals.

Menorca was successively possessed by the Phœnicians, Carthaginians, Romans, Vandals, and Arabs. On the conquest of Mallorca, in A.D. 1229, by Don Jayme of Aragon, surnamed the Conqueror, Menorca, which was still held by the Moors, became tributary to that prince. In A.D. 1287 the island was conquered by Alfonso, grandson of Don Jayme the Conqueror, who banished or enslaved the Moorish inhabitants. In the reign of Charles V. it was seized, but soon evacuated, by Barbarossa. It remained subject to the crown of Spain till the year 1708, when the earl of Stanhope, with 8000 British troops, attacked Mahon, and by shooting into the town arrows to which were attached papers threatening the garrison with labour in the mines unless they immediately surrendered, he induced them to capitulate. The conquest of the island followed that of its capital, and was confirmed by the treaty of Utrecht: the English retained possession of Menorca till the year 1756, when

Mahon was attacked by the French under Marshal de Richelieu, and Admiral Byng having failed in relieving it, the island fell into the hands of France. At the peace of 1763 it was restored to the English, from whom it was wrested by the Spaniards in 1782; it was retaken in 1798, and finally ceded to Spain at the peace of Amiens in 1802.

In Menorca, the spring of the year is generally clear, mild, and temperate; the summer is intensely hot; the autumn is the season of the annual rains, which are exceedingly heavy; the winter is often cold, though snow and ice are rare. On the whole the climate is less agreeable than that of Mallorca; the air is more humid; and the summer heats more oppressive, which arises from the comparatively level character of Menorca. The only eminence deserving the name of mountain is Monte Toro in the centre of the island, the greater part of which is unsheltered from the violent north winds which in the winter rage in the Gulf of Lions, while the heats of summer are untempered by mountain breezes. The surface of the country is a gently undulating plain, rocky and barren, or partially clothed with wild olives and corn. The southern shore is the most level. The soil is for the most part poor and sandy; that on the slopes is much richer than that of the low grounds.

The mineral productions of Menorca are limestone, freestone, marble of various colours (little used however by the natives), slate, of which a quarry is worked at Cape Mola on the east side of the island, gypsum, used for cement, and potters' clay. There are a few lead-mines, very unproductive, and iron-ore is found in small quantities.

The vegetation of Menorca is very similar to that of Mallorca, though it is much less abundant, and the trees seldom attain to so large a size. Aromatic plants and herbs, many with medicinal qualities, grow in profusion. Wheat, barley, and a little maize are cultivated, though not enough for the consumption of the island. The return on an average is six or seven for one. Olive-trees grow almost without culture; little oil is made from their fruit, which is generally sold as such. Vines are plentiful, and produce both white and red wine. Fruit is abundant: there are oranges, lemons, pomegranates, figs, apples, pears, and almonds; the melons are of superior flavour. Date-palms will grow in sheltered spots, but yield no fruit. Capers grow spontaneously in all parts of the island. Flax, hemp, saffron, and the cotton-tree thrive well, but are little attended to. Vegetables are no less abundant than fruit, and consist chiefly of peas, beans, onions, cauliflowers, broccoli, tomatoes, endive, cucumbers, and gourds, all excellent in quality.

Menorca is rich in cattle, sheep, goats, and pigs; and also in game, as partridges, quails, and rabbits; woodcocks, snipes, and teal are plentiful in winter. Fish, especially anchovies, with oysters, lobsters, and other crustacea, abound on the coasts. Lizards swarm, and there are a few venomous reptiles, but no beasts of prey.

The natives are engaged either in agriculture, fishing, or commerce. The imports consist of corn, oil, brandy, tobacco, coffee, sugar, spices, hardware and cutlery, linen and woollen goods, timber, cordage, tar, and gunpowder. The exports are wines, wool, cheese, salt, honey, and wax. The possession of Menorca by the English during the last century did much to promote its trade and commerce; a spirit of activity and enterprise was awakened, and the natives, besides engaging in mercantile pursuits, fitted out vessels as privateers, and enriched themselves at the expense of France and Spain. But since the island has reverted to the Spaniards, trade and commerce have greatly declined.

The island is divided into four *terminos*, or districts, Ciudadela, Mahon, Alhayer, and the united *terminos* of Ferarias and Mercadal. In each is a town of the same name, the capital of the district. The population of the whole island is about 35,000, of which the *termino* of Ciudadela contains 8000, of Mahon 19,000, of Alhayer 4000, and of Ferarias and Mercadal 4000. Ciudadela, the present metropolis of Menorca, is situated on the north-west coast, on a small port, shallow and difficult of entrance. The city is fortified, and its walls are partly of Moorish, partly of more recent construction. Its population is above 4000. The streets are narrow, crooked, and wretchedly paved; many of the houses are neat, and some handsome. A cathedral, two parish churches, several convents, an hospital, a barrack, with a government-house, are the public buildings.

Ciudadela, though the residence of the captain-general, the bishop, and the nobility of Menorca, is inferior in importance to Mahon, or Port Mahon, on the opposite or south-eastern shore of the island, and 24 miles from the capital, with which it communicates by a carriage-road. Mahon is said to have been founded by and called after Mago, a distinguished Carthaginian commander. It is picturesquely situated at the bottom of a deep and narrow bay, on rock much elevated above the sea, and in many places undermined by the waves. Mahon was formerly surrounded with walls, the only relic of which is a gateway of Arabian architecture. The streets are steep, narrow, crooked, and badly paved: the governor's house, town-hall, hospital, barracks, and other public buildings are scarcely worthy of notice; the private houses are neat and clean, built with taste, but often without regard to comfort, for many being on the English model, they are ill adapted to the sultry climate. Some of their roofs are tiled, and some flat-terraced in the Oriental style. The port of Mahon is one of the best in the Mediterranean, or (it has been said) in the world, as a large fleet of line-of-battle ships may ride within it in seven or eight fathoms water, perfectly sheltered from every wind. The Spaniards have a saying, 'The ports of the Mediterranean are June, July, August, and Port Mahon.'

'Los puertos del Mediterraneo son Junio, Julio, Agosto, y Puerto Mahon.'

Port Mahon alone made the possession of Menorca an object of contention among the maritime nations of Europe during the past century. In the harbour are four rocky islets; on one stands an hospital, on another a quarantine establishment, on a third a lazaretto, and on the fourth an arsenal with naval storehouses—all erected by the English. At a short distance from Mahon stood Fort St. Philip, famed in the military annals of the last century, and once a league in circumference. It is now a heap of ruins, having been blown up by the Spaniards in 1803, to prevent its being used by the English, in case they should again seize the island.

The other ports of Menorca are, Fornels, a well sheltered bay, capable of holding a large fleet, and Adaya, a small harbour, full of rocks and shoals, and only entered by fishing-craft.

Alhayer, Mercadal, and Ferarias, the other district-capitals of Menorca, are little more than villages, and contain nothing worthy of notice.

Monte Toro is in the form of a cone, with a flat summit which is occupied by an Augustin convent, to which pilgrimages are often made by the natives with bare feet. Mount St. Agatha, the eminence next in importance, is supposed to have been a military post in the time of the Romans, and traces of a Moorish fortification are still visible on its summit. Two miles south of Ciudadela is a curious grotto, called 'La Cava Perella,' full of stalactites and stalagmites; and in the same vicinity is another cavern containing a pool or lake of salt-water.

Menorca is not rich in antiquities. About two miles from Alhayer is a rude pyramidal ruin of Druidical character, ascribed to the Phœnicians, the earliest colonists of the island; but whether it be temple, tomb, or watch-tower is yet disputed. Punic, Greek, Roman, Gothic, and Arab coins have been discovered; together with small statues of bronze, vases, lamps, urns, &c., chiefly of Roman origin.

In character and manners, the Menorquines resemble the natives of Mallorca. They are equally attached to their native soil, and to their customs and religion, but they are less indolent and more enterprising. Like the Mallorquines they are proud, boastful, and irascible, yet ordinarily mild and peaceable. The same dress and language are common to both.

(Dameto and Mut, *History of the Balearic Kingdom*; Armstrong's *History of the Island of Minorca*; Laborde, *Itinéraire Descriptif de l'Espagne*; St. Sauveur, *Travels through the Balearic and Pithyusian Islands*.)

ME'NSTRUUM. [SOLVENT.]

MENSURATION is the name given to a branch of the application of arithmetic to geometry, which shows how to find any dimension of a figure, or its area, or surface, or solidity, &c., by means of the most simple measurements which the case will admit of. We need hardly say that a complete treatise on this science would involve every branch of mathematical science. We shall in this article collect together the most important rules, the method of using which will be obvious to all who can employ the trigono-

metrical tables. By the length of a line we mean the number of linear units contained in it, and by its square and cube the number of units multiplied by itself once and twice.

The measurement of lengths and directions resolves itself for the most part into the determination of a side or angle of a triangle, when other sides or angles are given. The triangle may be either on a plane or on a sphere; but we refer the latter to SPHERE, since the use of spherical trigonometry can only be well explained in connection with astronomy. Let a, b, c be the sides of a triangle, and $A, B,$ and C the opposite angles. If the triangle be right angled at C , we have the following formulæ:—

$$\begin{aligned} a &= c \sin A = c \cos B = b \tan A = b \cot B \\ b &= c \sin B = c \cos A = a \tan B = a \cot A \\ c &= \frac{a}{\sin A} = \frac{a}{\cos B} = \frac{b}{\sin B} = \frac{b}{\cos A} \end{aligned}$$

$$c = \sqrt{a^2 + b^2} \quad a = \sqrt{c^2 - b^2} \quad b = \sqrt{c^2 - a^2}$$

The preceding formulæ contain the solution of every case of right angled triangles.

We now pass to oblique angled triangles, of which there are four cases.

1. Given the three sides, a, b , and c , to find the angles. Let the perpendicular let fall from C upon the longest side c divide it into two segments α and β adjacent to a and b , and let b be $\angle A$. Then the equations

$$\beta + \alpha = c, \quad \beta - \alpha = \frac{(b-a)(b+a)}{c}$$

(in which $\beta - \alpha$ is easily found by logarithms), will give β and α . Then

$$\cos B = \frac{\alpha}{a} \quad \cos A = \frac{\beta}{b} \quad C = 180^\circ - (A+B)$$

Another method is as follows. Compute M from the following*

$$s = \frac{a+b+c}{2} \quad M = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$\tan \frac{1}{2} A = \frac{M}{s-a} \quad \tan \frac{1}{2} B = \frac{M}{s-b} \quad \tan \frac{1}{2} C = \frac{M}{s-c}$$

2. Given two sides a and b , and the remaining angle C , required c, A , and B . Firstly, to find the angles, determine

$$\frac{1}{2} (B+A) \text{ from } \frac{1}{2} (B+A) = \frac{1}{2} (180^\circ - C)$$

$$(B-A) \text{ from } \tan \frac{1}{2} (B-A) = \frac{b-a}{b+a} \cot \frac{1}{2} C$$

$$A = \frac{1}{2} (B+A) - \frac{1}{2} (B-A); \quad B = \frac{1}{2} (B+A) + \frac{1}{2} (B-A)$$

$$c = b \frac{\sin C}{\sin B} = a \frac{\sin C}{\sin A}$$

To find the third side without the aid of the angles, assume

$$\sin \theta = \frac{\sqrt{(ab) \cdot 2 \cos \frac{1}{2} C}}{a+b}, \text{ then } c = (a+b) \cos \theta;$$

or

$$\tan \theta' = \frac{\sqrt{(ab) \cdot 2 \sin \frac{1}{2} C}}{a-b}, \text{ then } c = \frac{a-b}{\cos \theta'}$$

3. Given a, b , and the angle A ; to find the rest:

$$\sin B = \frac{b}{a} \sin A, \quad C = 180^\circ - (A+B), \quad c = \frac{a \sin C}{\sin A}$$

4. Given a , and two of the angles, to find the rest. It is unnecessary to distinguish the angles given, as two immediately determine the third.

$$b = a \frac{\sin B}{\sin A}, \quad c = a \frac{\sin C}{\sin A}$$

The area of the triangle is

$$\frac{ab \sin C}{2} \text{ or } \frac{bc \sin A}{2} \text{ or } \frac{ca \sin B}{2} \text{ or } \sqrt{(s-s-a)(s-s-b)(s-s-c)}$$

The perpendiculars let fall from the vertices A, B , and C , upon the opposite sides, are severally $2 \sqrt{(s-s-a)(s-s-b)(s-s-c)}$ divided by a, b , and c .

$$\text{Diam. of inscribed circle } 2 \sqrt{(s-s-a)(s-s-b)(s-s-c) \div s}$$

$$\text{Do. of circumscribed circle } \frac{a}{\sin A} \text{ or } \frac{b}{\sin B} \text{ or } \frac{c}{\sin C}$$

* This convenient adaptation of a well-known formula is found, we believe, for the first time in Professor Wallace's lately published work on Mathematical Theorems and Formulæ (Longman, 1839).

$$\text{or } abc \div 2 \sqrt{(s-s-a)(s-s-b)(s-s-c)}$$

Segments of c made by perpendicular from C ,

$$\text{Adjacent to } a, \frac{c^2 + a^2 - b^2}{2c}; \text{ to } b, \frac{c^2 + b^2 - a^2}{2c}$$

Segments of c , by line bisecting C ,

$$\text{Adjacent to } a, \frac{ac}{a+b}; \text{ to } b, \frac{bc}{a+b}$$

$$\text{Line bisecting } C = \frac{2 \sqrt{(ab s(s-c))}}{a+b} = \frac{2ab}{a+b} \cos \frac{1}{2} C$$

$$\text{Line bisecting } c = \frac{1}{2} \sqrt{(2a^2 + 2b^2 - c^2)}$$

The area of a rectangle (in square units), and that of a parallelogram, is the product of the units in the base and perpendicular distance of the opposite sides. But if two sides only be parallel, half the sum of the parallel sides must be multiplied by the perpendicular distance between them. In other cases, the figure must be measured by dividing it into triangles, except when it is either a four-sided figure capable of inscription in a circle, or a regular polygon. Every triangle is half of the rectangle contained by any one of its sides, and the perpendicular let fall from the opposite vertex.

If a, b, c , and d be the sides of a four-sided figure inscribed in a circle, and s their half-sum, the area is

$$\sqrt{(s-a)(s-b)(s-c)(s-d)}$$

If a be one of the sides of a regular polygon of n sides, the area of the figure and the diameters of the circumscribed and inscribed circles are

$$\frac{n a^2}{4} \cot \left(\frac{180^\circ}{n} \right), \quad a \div \sin \left(\frac{180^\circ}{n} \right), \text{ and } a \div \tan \left(\frac{180^\circ}{n} \right)$$

Tables connected with this subject are given in the *Tables of Logarithms*, and corresponding tables for the solids in *SOLID GEOMETRY*. For the method of measuring irregular areas, see *QUADRATURE*, METHOD OF.

The whole of the measurement of the circle depends upon the ratio of the circumference to the diameter, which is called π , and is 3.1415927 very nearly, or $\frac{22}{7}$ roughly, or $\frac{355}{113}$ very nearly. [ANGLE.] So many simple derivations from this number are practically useful, that we shall give a table of them, accompanied by their logarithms, first giving a method of multiplying and dividing by π , which is a correction of the use of $\frac{22}{7}$. To multiply by π , multiply by 22 and divide by 7; from the result take one-eighth of the hundredth part of the multiplicand as a correction; the result is too great only by about its 200,000th part. To divide by π , multiply by 7, divide by 11 and 2, and to the result add the eighth part of the thousandth part of the dividend; the result is too small by very nearly its 100,000th part.

The table just referred to is as follows:—

	Number.	Logarithm.
π	3.1415927	0.4971499
$\pi : 2$	1.5707964	0.1961199

To find the circumference from the diameter, multiply by π ; to find the diameter from the circumference, multiply by $1 : \pi$; to find the area from the diameter, multiply the square of the diameter by $\pi : 4$; to find the area from the radius, multiply the square of the radius by π ; to find the diameter from the area, multiply the square root of the area by $\sqrt{(4 : \pi)}$; to find the area from the circumference,

multiply the square of the circumference by $1:4\pi$; to find the circumference from the area, multiply twice the square root of the area by $\sqrt{\pi}$; to find the ordinate perpendicular to a diameter, take the square root of the product of the segments into which it divides the diameter.

To find the area contained between two concentric circles, multiply the product of the sum and difference of the radii by π .

The arc of a circle and its subtended central angle are connected as follows: the arc which is equal to the radius subtends an angle of $57^\circ.3$ very nearly; or it may be easily remembered as 57 degrees and *three-tenths* of a degree, diminished by one-fourth of a minute and one-fifth of a second; being $57^\circ 17' 44''.8$, or $206264''.8$. To find an angle from its arc (the radius being known), multiply the arc by 57.3 , and divide by the radius; the result is too great by about three-quarters of its 10,000th part, and is in degrees and decimals of a degree. To find the arc from its angle, turn the angle into degrees and decimals, multiply by the radius, and divide by 57.3 ; the result is now too small by about three-quarters of its 10,000th part.

To find the area of a sector, find the arc (if only the angle be given), and multiply it by half the radius. To find the area of a segment contained between an arc and a chord, find the sector, and from it subtract the triangle formed by the terminal radii and the chord. [SEGMENT.]

To find the length of an arc, when the radius is not known, measure the chord of the arc, and the chord of its half; from eight times the chord of the half subtract the chord of the whole, and take one-third of the remainder. For an arc not exceeding 60 degrees, the error is less than the 7000th part of the whole.

The preceding are the principal rules of mensuration, of which the necessity occurs in the elementary parts of the subject: those which remain are connected with solid geometry, and the most essentially as follows.

The number of cubic units in the content of a rectangular solid (or parallelepiped; there is no shorter term for this elementary form of solid figures) is the product of the number of linear units in its three adjacent sides. The content of a prism or cylinder is the product of the number of square units in its base and the number of linear units in its altitude. The content of a pyramid or cone is one-third of the base multiplied by the altitude. The surfaces of a prism or pyramid must be found by computing those of their several faces. The surface of a common cylinder (not including the bases) or of a right prism is the circumference of the base multiplied by the altitude; that of a common cone is half the product of the circumference of the base and the slant side.

The following formulæ relate to the sphere. To find the surface from the radius, multiply the square of the radius by 4π , or the square of the diameter by π ; to find the content from the radius, multiply the cube of the radius by $4\pi:3$, or the cube of the diameter by $\pi:6$; to find the radius from the surface, multiply the square root of the surface by $\sqrt{1:4\pi}$, to find the diameter, multiply the square root of the surface by $\sqrt{1:\pi}$; to find the radius from the content, multiply the cube root of the content by $\sqrt[3]{3:4\pi}$; to find the diameter, multiply the cube root of the content by $\sqrt[3]{6:\pi}$; to find the surface from the content, multiply the cube root of the square of six times the content by $\sqrt[3]{\pi}$, to find the content from the surface, multiply the square root of the cube of the surface by $1:6\sqrt{\pi}$. [SPHERE.]

For other formulæ and methods, the detached articles on the different subjects may be consulted; or Hutton's or Bonnycastle's elementary works on mensuration.

MENTHA PIPERITA (Peppermint), a plant common in many parts of Britain, but cultivated for medical purposes. The dried plant, which is more powerful than the fresh, is of a lively green, with a peculiar aromatic odour, and a pleasant camphor-like taste, at first burning, but at last causing an enduring sensation of cold in the mouth. The dried herb is used for the preparation of a distilled water, and of a volatile oil, from which oil spirits or essence of peppermint is prepared. Of the oil three varieties occur in commerce, the German, English, and American. Twenty pounds of the herb yield from four to six drachms; but if the flowers be also distilled, the same weight will yield four ounces. It is often adulterated with oil of turpentine, oil of marjoram, and absolute alcohol. When pure it is of a whitish yellow, yellow, or even green colour; odour very strong, taste burning, camphor-like, causing a sense of

coldness in the mouth. The oil is at first limpid, but becomes thicker, like a fixed oil. European oil does not deposit a stearopten, but the American easily forms long colourless four-sided prisms, which possess the odour of the oil. The American oil is more soluble in alcohol than the German; specific gravity 0.92, but when rectified 0.90. The action on the human system of any of the preparations of mint is stimulant and antispasmodic. The oil is used to be added to drastic or griping purgatives, and in other cases. It proved of considerable utility in bringing about reaction in the collapsed stage of Asiatic cholera.

MENTHA PULEGIUM (Pennyroyal), an indigenous species of mint, smaller than most of the others, and of which the entire herb, except the root, is officinal. The odour is strong and peculiarly aromatic; taste herbaceous and bitterish. It has a stimulant and antispasmodic property, similar to most mints, but is supposed to possess also a specific power over the uterus, which has been much over-estimated. A distilled water, a spirit, and volatile oil are prepared from it, as from the preceding species.

MENTHA VIRIDIS (Spearmint), a plant of Britain, very much resembling *M. piperita*; the colour however is of a deep green. It is also frequently confounded with *M. crisp*, than which it has a stronger and more agreeable odour, but weaker than peppermint. It has not the aromatic odour of that plant, nor does it leave the sense of coldness in the mouth. From it are prepared a distilled water, a spirit, and a volatile oil, which are used as the former.

MENTA. [MAINZ.]

MENU. [MANU.]

MENU'IA. [MENTURA.]

MENYANTHES TRIFOLIATA (officinal part, the leaves), a plant common in our bogs, and hence called bog-bean, as its leaves resemble the common bean. The leaves are ternate, petiolate, and even when dried have a fine green colour, but are without odour; they possess an enduring bitter taste. Six hundred parts of the fresh herb dry into thirty-nine; ten pounds of the dried plant yield two pounds and three-quarters of extract. It contains an extractive (Menyanthin), which Brandes says forms a white, transparent, and, when highly dried, pulverisable mass of an intense degree of bitterness. Trommsdorff says he obtained a yellowish brown, clear, very viscid, non-pulverisable, bitter extract.

It is a tonic and febrifuge medicine of undoubted efficacy, but greatly neglected in the treatment of disease. The chief use said to be made of the large quantity annually collected is to substitute it for hops in brewing, a proceeding which is both illegal and detrimental to the beer, since, though bitter, it does not possess the aromatic quality of the hop.

MERCAPTAN, a compound of hydrogen, carbon, and sulphur, discovered by Zeise, and so called from its energetic action on binoxide of mercury (*corpus mercurium captaus*). It is prepared by distilling a mixture of sulphovinate of barytes and a strong solution of protosulphuret of barium. A volatile liquid and water pass over into the receiver, while sulphate of barytes remains in the retort; the ethereal product floats on the water, and when removed and carefully distilled, it separates into thionioether and mercaptan, the properties of which are, that it is a colourless liquid, has a penetrating alliaceous smell, and a peculiar sweetish taste; its specific gravity is 0.842, it boils at 144° , and remains fluid at 8° . Water dissolves it sparingly, but æther and alcohol unite with it in all proportions; it has no action on litmus paper. Acetate of lead, but not nitrate of lead, gives a plentiful yellow colour in the solutions of mercaptan. When added to binoxide of mercury, energetic action ensues, water is generated, and a colourless crystalline compound is formed; with bichloride of mercury a similar product is obtained, attended with the formation of hydrochloric acid.

According to Zeise, the ultimate composition of mercaptan is—

Six equivalents of hydrogen	6
Four equivalents of carbon	24
Two equivalents of sulphur	32
Equivalent . . .	62

He however considers it as a *hydruret* of a compound base which he calls *mercaptum*, presumed to consist of five equivalents of hydrogen 5, four equivalents of carbon 24, and two equivalents of sulphur 32 = 61.

When mercaptan is made to act upon potassium, *mercaptide* of potassium is formed, and one equivalent of hydrogen is evolved; the constitution therefore of mercaptum and mercaptan is analogous to that of cyanogen and hydrocyanic acid.

MERCATOR, GERARD (whose real name was Kauffman, of which *Mercator* is the Latin equivalent), was born at Rupelmonde in East Flanders, in the year 1511. He applied himself with great industry to the sciences of geography and mathematics, and was patronised by the emperor Charles V., and appointed, in 1559, cosmographer to the duke of Juliers. He gave his name to the method of geographical projection now usually employed in the construction of nautical maps, in consequence of his having first represented the meridians by equidistant parallel lines, and the parallels of latitude by straight lines at right angles to the meridian, but he did not know the distance which ought to separate these parallels. Nicholas Mercator is said to have discovered the law which regulates these distances; but the English mathematicians having refused to pay for the promulgation of his discovery by accepting a pecuniary challenge which he is said to have proposed to them, he died without communicating it even to his friends. The credit of first investigating the principles of that projection, and applying them to the purpose of navigation, appears to be due to Edward Wright. Gerard Mercator died at Doesburg, Dec. 2, 1594. His published works are entitled 'De Usu Annuli Astronomici,' Leod., 1552; 'Chronologia,' Cologne, 1568, fol.; 'Tabulae Geographicae,' Cologne, 1578, fol.; 'Harmonia Evangelicorum,' Doesburg, 1592, 4to. His maps were collected in one volume, 4to., in 1594; and another edition was published in 1623, containing 156 maps.

(Hutton's *Mathematical Dictionary*; Montucla, *Histoire des Mathématiques*; Robertson's *Dissertation on the Rise and Progress of Navigation*.)

MERCATOR, NICHOLAS (whose real name was Nicholas Kauffman), was born at Holstein, in Denmark, in 1640. At an early age he was engaged in a correspondence with some of the principal geometers of Denmark, Italy, and England. In 1660 he came to England; and shortly after the formation of the Royal Society, he was elected a member of that body. The date of his death is uncertain. According to Dr. Hutton, it took place in England in the year 1690 (*Mathematical Tracts*), or in 1694 (*Mathematical Dictionary*); but, according to Weiss (*Biog. Univers.*), he died at Paris, February, 1687. The reputation of Mercator rests principally upon a method, of which he was the author, whereby the area of the spaces comprised between the hyperbola and its asymptote may be determined arithmetically to any degree of approximation required; and upon the application of this method to the construction of logarithmic tables. It had been shown, as early as the year 1647, by Gregory St. Vincent, and subsequently by Mersenne, that these areas, if they could be computed, would give the logarithms of the corresponding abscissæ measured along the asymptote. [LOGARITHMS.] It was also known that in the equilateral hyperbola whose semi-axis = $\sqrt{2}$, the relation between the ordinate and abscissa

was expressed by the equation $y = \frac{1}{1+x}$; and Wallis had

shown in his 'Arithmetica Infinitorum,' published in 1655, that if the equation of a curve be represented by $y = 1 + x + x^2 + x^3 + \&c.$, its area would be correctly expressed

by the infinite series $x + \frac{x^2}{2} + \frac{x^3}{3} + \&c.$ Wallis however,

although his attention had been particularly directed to the subject, did not observe the almost obvious analogy between the equations $y = 1 + x + x^2 + \&c.$, and $y =$

$\frac{1}{1+x}$, as he could not have failed to do, had he chanced to

perform the simple division indicated by the fraction $\frac{1}{1+x}$,

for he would then have seen that the latter equation was identical with $y = 1 - x + x^2 - x^3 + \&c.$ Mercator performed this division, and moreover describes the several steps of the operation with such minuteness, that one might almost suppose it to have been the first operation of the kind that had at that time been effected. He then proceeded to determine the required area, by considering it made up of a number of ordinates very near to each other, which method Kepler had previously employed in approximating to the area of a planet's orbit, and in this way he correctly inferred that the area corresponding to the abscissa $1 + x$, that is,

the hyperbolic logarithm of $1 + x$, was $x - \frac{x^2}{2} + \frac{x^3}{3} - \&c.$

These investigations were published by Mercator in 1668, in a work entitled 'Logarithmotechnia, sive methodus construendi logarithmos nova, accurata et facilis,' 4to., London. Wallis, who soon improved upon this method, says, when speaking of the work in a letter addressed to Lord Viscount Brouncker, 'With this book, which has just appeared, I was so much pleased, that I could not quit it until I had completed its perusal. The doctrine by which the logarithms may be expeditiously constructed is perspicuously and ingeniously treated.' (*Phil. Trans.*, 1668.)

Mercator has been charged with dishonourably appropriating the discoveries of others, and with meanly withholding the publication of some which really belonged to him. [MERCATOR, GERARD.] In the 'Philosophical Transactions' for 1670, there is a paper by him, entitled 'Considerations concerning the Geometric and Direct Method of Signior Cassini for finding the Apogees, Excentricities, and Anomalies of the Planets,' besides which he has left the following works: 'Geographia,' Danzig, 1651, 12mo; 'Repositio mathematicæ sublimis,' Copen., 1653, 4to.; 'Emendatione Annua d'atribus duabus, quibus exponuntur et demonstrantur Cycli Solis et Lunæ,' 4to.; 'Hypothese astronomica nova et consensus ejus cum observationibus,' Lond., 1664, fol.; 'Institutionum Astronomicarum libri duo,' Lond., 1676, 8vo.; 'Euclidis Elementa Geometrica,' Lond., 1678, 12mo.

(Hutton's *Mathematical Tracts*; Montucla, *Hist. des Mathém.*; *Biog. Univ.*)

MERCATOR'S PROJECTION. It is our object in this article to endeavour to describe the projection, the use of which constitutes the principal difference between the methods of travelling by land and by sea, in such a manner as rather to give information to the landsman than the rules by which the mariner is guided. Perhaps there is no point of navigation on which a person who is neither a seaman nor a mathematician has so little chance of gaining any information from popular works.

We shall suppose the ship a mathematical point in comparison with the earth, and imagine the whole of the latter to be covered by sea. Also let the ship be always sailing before the wind, and no allowance for leeway or currents to be necessary. Throw out also the variation of the compass, that is, suppose the needle always to point due north.

A ship thus circumstanced, if it should continue sailing due north, would in time reach the north pole on a meridian circle of the sphere, on which, if it still kept its course, it would proceed due south, and would at last reach the south pole: such a ship would never change its longitude, except at the moment of passing either pole, when the longitude would alter at once by 180 degrees. If however the vessel sailed continually due east or due west, it would sail upon a small circle of the sphere, being always at the same distance from the pole, and always in the same latitude. In the first case the differences of latitude would give the distances sailed over, at the rate of 60 nautical miles to a degree; in the second case, the differences of longitude, reduced in the same way, and the results multiplied by the cosine of the latitude, would serve the same purpose.

But suppose that the vessel took an intermediate course, say north-east. It would not sail on any circle of the sphere, great or small; for by hypothesis the line of the course is always making an angle of 45 degrees with the meridian; and there is no circle (unless it be the meridian itself, or a parallel of latitude, the equator included) which always makes the same angle with the meridian. Neither could the vessel, keeping such a course, reach the pole; for at the moment when it touches the pole, it is sailing north

whereas by hypothesis it is always sailing north-east. The fact is, that a curve which makes equal angles with all meridians must be a spiral which approaches the pole, encircling it with an infinite number of folds, but never actually reaching it, as in the following diagram, in which the curve 1, C, 2, 3, 4, &c., is that on which a ship would sail from 1 towards the north pole on a course east-north-east, and the curve 1, 5, 6, 7, 8, &c., is that of a course west-south-west towards the south pole. The dotted part of the figure is supposed to be on the other, or the invisible, side of the sphere. A ship sailing from A to B over A C B, keeps one course; but were it to sail over the great circle A D B, the course must be perpetually altering.

The spiral A C B is the only one on which a ship should sail directly from A to B, though there is an infinite number of such curves which pass through both A and B, the reason being, that in every other spiral except A B one or more complete circuits in longitude must be made, and the ship would come again to the meridian passing through A before it reaches B. In the same manner a spiral might be

found, passing through A and B, which cuts the meridian of A five hundred times before it passes through B. Of course the shortest course is always preferred; and it is the object of Mercator's projection to lay down such a map of the world that the straight line joining two points shall be the map of the course which must be followed in order to sail from one to the other in the most direct manner, consistently with always keeping the same point of the compass.

The spirals above described are called loxodromic spirals, or rhumb lines, and under the latter term their mathematical properties are explained. Our present object is to turn the globe into one of Mercator's maps, in a manner which will give the unmathematical reader some idea of its construction. For this purpose suppose the map of the world to be painted on the globe, and let the globe be made of a thin and very elastic material. Let the elasticity of this material increase as we go towards either pole, and so rapidly that it becomes as great as we please at and near the poles. Let the equator E Q be immovably connected with the internal centre (supposed fixed) of the globe. If then the north and south poles be pulled away from the equator, the thin membrane of the sphere will be extended; and if the pull be continued until the poles are sufficiently distant, a large portion of the sphere on each side of the equator will assume a cylindrical form, or one nearly cylindrical; and the greater elasticity of the upper parts will cause the smaller folds of the different spirals to be much more extended than the larger ones, so as to become equal to them. Let the mathematical hypothesis implied in the preceding be carried to its extreme limit, that is, let the poles be pulled to an infinite distance; and let the law of the elasticity be such, that the several loxodromic spirals shall have precisely similar successive folds on the resulting cylinder, that is, let them take a regular screw-like form. The meridians will then become straight lines parallel to one another; and if the membrane be then fixed in its cylindrical shape, that is, if it lose its elasticity, and if one of the meridians be slit all the way down, and the cylinder unrolled into a plane, we shall have before us Mercator's projection, as shown in the following diagram. The degrees of longitude remain everywhere the same, but the latitude increase sensibly. The map goes up to 80° of latitude, and any part of the remaining 10° might be drawn; but no space would be sufficient for the whole of the remainder. Any two points, A and B, being given, the line A B joining them points out, on the supposition that all the meridians look towards the north, the most direct course on which a ship can sail from one to the other: if a compass were placed

at A, then A B would show, A K being the north direction, the point of the compass on which to steer. Again, from C to D the most direct course is on the dark line C D; but C E, E D, is another way of coming to the same point. It must be remembered that the extreme lines of the right and left represent the same meridian, as they coincided before the cylinder was divided for the purpose of being unrolled.

It thus appears that we have a map on which the sailing course between any two places is found by simply drawing a right line. Another advantage, depending upon the nature of the rhumb line however, and not on the projection, is the simplicity of the rule by which the distance sailed can be determined. This is pointed out in RUMBLE-LINE.

The preceding is Mercator's projection of the whole 360 degrees of longitude up to 80 degrees of latitude. A chart, as in other cases, is a part of the projection, enlarged to a convenient size.

MERCENARIA, Schumacher's name for the *Venus mercenaria* of authors, which passes current as money, under the name of Wampum, among the Indians of North America. [VENERIDÆ.]

MERCIA. [ENGLAND.]

MERCURY, or QUICKSILVER. This metal, which possesses the remarkable property of being fluid at usual temperatures, has been known from the remotest ages. Although it is met with in very large quantity, yet the mines occur in comparatively few places; those of Almaden in Spain, and Idria in Carniola, are the most important. There are however mines of this metal in Hungary, Transylvania, and the district of Deux Ponts in Germany. Mercury has been obtained for a very long time in China and Japan, and although the amount of the produce is unknown, there is every reason to think it is considerable; it is also found at Huancavelica in Peru.

Mercury is always obtained from cinnabar, which is the bisulphuret of the metal; it is found in the red-sandstone associated with coal at Almaden. Sometimes, as in the district of Deux Ponts, the cinnabar occurs in the subordinate porphyries; and at Idria it is found in the subordinate bituminous schist, but rarely in limestone itself.

The cinnabar which is found in coal-sandstone is often accompanied with argillaceous and bituminous schist, and is associated with fishes and plants; often with combustible fossils, and sometimes even intimately mixed with coal.

Pliny states (xxiii. 7) that Callias, an Athenian, discovered the preparation of vermilion, or cinnabar, B.C. 505. He also mentions the mines of Almaden [ALMADEN] as producing in his time 10,000 Roman pounds annually; but this was not the amount which the mines could have produced, for the supply was purposely limited. Le Play, a French geologist, who visited Almaden in 1833, describes the mines as being richer than at any former period, furnishing annually nearly 2,244,000 pounds of mercury. About 700 workmen are employed underground, and 200 in the operations connected with the extraction of the metal from the ore at the surface.

Formerly mercury was imported in packages of fifty or sixty pounds weight; the metal was poured into a fresh sheep-skin, from which the wool was taken off, the ends were tied tight, and the sort of bag thus made was enclosed in a second skin, and that in a third, and three or four bags were packed in close barrels. Of late years however mercury has been brought to this country in wrought-iron bottles.

Various processes are adopted for the purpose of separating the mercury from the ore, all of which depend upon the volatility of the metal, its conversion into vapour in distilling vessels or retorts, and its condensation by cold. In order to separate the sulphur from the metal, either iron or lime may be employed; the first forms sulphuret of iron, and the latter of calcium, with the sulphur, and the metal is thus set free, volatilized, and condensed. The retorts employed are made of cast or sheet iron, or earthenware.

According to Dumas the following mines yield annually the annexed number of quintals of mercury (a quintal is 108 lbs. avoirdupois nearly):—

Almaden	25,000	to	32,000
Idria	6,000		10,000
Hungary			
Transylvania	700		700
Deux Ponts	400		500
Palatinate	180		200
Huancavelica	3,000		3,000
	35,280		46,400

We may perhaps reckon the average at about 2000 tons.

The properties of mercury are, that it is fluid, of a silvery white colour, and possesses a high degree of lustre; it is inodorous, tasteless, unacted upon or very slightly by exposure to air at common temperatures, and not at all by water at any temperature. The specific gravity of mercury is about 13.568. It boils at 670°; the density of its vapour is 6.976; and yet, as shown by Priestley, it vaporises at common temperatures, and Faraday has confirmed the observation. At 40° below Zero, mercury becomes solid, crystallizes in octohedrons, and gives a dull sound like lead; at the moment of congelation it contracts considerably; for while its density at 47° is 13.545, that of frozen mercury is 15.612; when in this state it is malleable, and may be cut with a knife.

Mercury is a good conductor of electricity and of heat, but its capacity for heat is extremely small; it expands uniformly at all temperatures between its boiling and freezing points. When mercury is pure it assumes the spherical form in small portions, but when it contains other metals, it forms into long striæ; a very minute admixture is sufficient to produce this effect; when thus impure it must be subjected to distillation, by which the mercury is volatilized, and the metals mixed with it remain; or it may be purified to a considerable extent from the more oxidizable metals by agitation with dilute nitric acid.

ORES OF MERCURY.—*Native Mercury*.—This occurs in but few places, and is met with in small cracks or crevices of the rocks in which the common ore occurs, and is frequently accompanied by red silver.

The principal localities are Almaden in Spain, and Idria in Carniola; some is also met with in the Palatinate.

Chloride of Mercury (*Horn Mercury*; *Baumerite*; *Musgraveite*).—Crystallized and in tubercular crusts. Primary form a square prism. Cleavage parallel to the lateral faces and the diagonal planes of the primary form; the latter are the more brilliant. Fracture conchoidal. Hardness 1.0 to 2.0. Readily scratched with the knife. Colour pearl grey, or yellowish grey. Lustre adamantine. Translucent. Specific gravity 6.482.

Heated by the blow-pipe, it is entirely volatilized, and it yields by analysis

Chlorine	14.89
Mercury	85.11

100°

Occurs principally at Moschelandsberg in Deux Ponts, but is also met with in Spain, Bohemia, and the Palatinate.

Cinnabar; *Vermilion*; *Bisulphuret of Mercury*.—This is the common ore of the metal. Occurs crystallized and massive. Primary form of the crystal an acute rhomboid. Cleavage easy, parallel to the lateral faces of a regular hexahedral prism. Fracture conchoidal. Hardness 2.0 to 2.5. Colour carmine red. Lustre adamantine, approaching metallic. Opaque, translucent, transparent. Specific gravity 8.098.

Heated by the blow-pipe, whitens a piece of copper held over it. Unacted upon by nitric or hydrochloric acid, but readily by a mixture of them.

It occurs in the places which have been mentioned; as Almaden, Idria, &c.

Massive Varieties.—Amorphous. Structure granular, compact. Fibrous and pulverulent.

Analysis by Klaproth:—

Sulphur	14.25
Mercury	85°

99.25

Native Amalgam.—Occurs crystallized and massive. Primary form a cube. Cleavage indicating the form of a rhombic dodecahedron. Fracture conchoidal. Hardness 3.0 to 3.5. Scratches gypsum; is scratched by fluor-spar. Colour silver white. Lustre bright metallic. Opaque. Specific gravity 14.119.

When heated by the blowpipe, the mercury is volatilized, and the silver remains in the metallic state.

Analysis by

	Klaproth.	Cordier.
Mercury	64	72.5
Silver	36	27.5
	100	100°

Massive Variety.—Amorphous. Structure compact. Sometimes semi-fluid by mixture with excess of mercury. Found in France, Spain, Sweden, Hungary, the Palatinate, &c.

Iodide of Mercury occurs in spots of a fine lemon-yellow colour in the variegated sandstone of Casas Viejas, Mexico. When exposed either to the air or ammonia it becomes black.

GASEOUS COMBINATIONS.—We now proceed to consider the action of the elementary gaseous bodies upon this metal.

Oxygen and Mercury combine to form two compounds, the protoxide and binoxide; they have however but little affinity for each other, and it is doubtful whether any combination takes place between them, even when the metal is exposed to and long agitated with moist air at common temperatures. The protoxide of mercury may be formed in several modes: when, for example, potash, soda, or lime-water is added to a solution of protonitrate of mercury, or to protochloride of mercury, protoxide of mercury is separated. Its properties are, that it is nearly black, insoluble in water and the alkalis, but dissolves readily in nitric acid; it decomposes and is decomposed by hydrochloric acid, water and protochloride of mercury being formed. With sulphuric acid it forms an insoluble salt. It is totally volatilized by heat; and even by being kept out of the action of light is apt to separate into mercury and peroxide. It is directed to be prepared in the London Pharmacopœia under the name of *hydrargyri oxydum*.

Protoxide of mercury is composed of—

One equivalent of oxygen	8
One equivalent of mercury	202

Equivalent . 210

Binoxide or Peroxide of Mercury.—This may be prepared by several processes; the simplest is that of exposing the metal nearly at its boiling point to the action of atmospheric air; it then absorbs oxygen, and is converted into a dark crystalline substance, formerly used in medicine under the name of *Mercurius præcipitatus per se*. It is inodorous, acrid to the taste, and is said to be slightly soluble in water. At a red heat it is decomposed, the mercury returns to the metallic state, and oxygen gas is evolved; the nitric, hydrochloric, and some other acids readily dissolve it, and the solutions formed are decomposed by potash, hydrated binoxide of mercury of an orange colour being precipitated.

This oxide may also be procured by dissolving mercury in nitric acid, and decomposing the nitrate formed, by the action of heat; and also by decomposing the bichloride of mercury by the addition of potash to the solution. As procured by the former of these modes it is called in the London Pharmacopœia *hydrargyri nitrico-oxydum*; it has a bright red colour and a crystalline appearance: when obtained by decomposing the bichloride of mercury it is less brilliant, and is more of an orange colour, and is the *hydrargyri binoxydum* of the Pharmacopœia.

Binoxide of mercury is composed of—

Two equivalents of oxygen	16
One equivalent of mercury	202

Equivalent . 218

Azote and Mercury, and Hydrogen and Mercury, do not combine.

Chlorine and Mercury form two compounds of very great importance in a medicinal point of view, the chloride or protochloride being the substance usually called calomel, and the perchloride or bichloride that which is commonly termed corrosive sublimate.

Chloride or Protochloride of Mercury (Calomel) may be obtained in several ways: 1st, by heating the metal in the gas; the residue, after washing, is the protochloride; 2nd, by adding a chloride, as common salt, to a solution of protonitrate of mercury, in which case the chloride of mercury is precipitated; 3rd, by adding the protoxide of mercury to hydrochloric acid, the results are chloride of mercury and water; lastly, there is the process of the Pharmacopœia, which is the best, and this consists in heating together common salt, mercury, and its bipersulphate; the results are, that when submitted to sublimation sulphate of soda remains, and the chloride of mercury formed is vaporized and condensed. It is the *hydrargyri chloridum* of the Pharmacopœia. The properties of chloride or proto-

chloride of mercury are, that when procured by precipitation it is a white pulverulent substance, whereas that obtained by sublimation is crystalline, hard, and dense; its specific gravity is 7.175; it is colourless, inodorous, insipid, and sometimes regular crystals are observed, the primary form of which is a square prism; by long exposure to light it becomes of a rather dark colour, owing to incipient decomposition. It is quite insoluble in water, not readily acted upon by dilute acids, and is decomposed by lime-water, potash, and soda, protoxide of mercury being separated. It is totally volatilized by heat.

Protochloride of mercury is composed of—

One equivalent of chlorine	36
One equivalent of mercury	202

Equivalent . 238

Bichloride or Perchloride of Mercury (Corrosive Sublimate) may also be formed by several processes. When, for example, the metal is heated in the gas, the soluble portion resulting from their action is bichloride of mercury; it may be formed by dissolving the binoxide in hydrochloric acid, the results being water, and the bichloride, which crystallizes when the solution is sufficiently evaporated; lastly, it is best formed by the process of the Pharmacopœia, which consists in heating a mixture of chloride of sodium and bipersulphate of mercury, by which sulphate of soda and bichloride of mercury are formed; the latter rises in vapour, and is condensed in the upper and cool part of the apparatus.

The properties of bichloride of mercury, the *hydrargyri bichloridum* of the Pharmacopœia, are, that it is a white semi-transparent crystalline mass, and perfect crystals are occasionally obtainable, the primary form of which appears to be a right rhombic prism. This substance is inodorous, its taste is nauseous and acrid, and it is a violent poison. Its specific gravity is 5.6200; water at 60° dissolves rather more than one-twentieth, and boiling water one-third of its weight. Light has no action upon this salt, but it partially decomposes the aqueous solution, chloride of mercury being precipitated. It is more soluble in alcohol, æther, hydrochloric acid, and solution of hydrochlorate of ammonia, than in water. It is totally volatilized by heat. Lime-water, potash, and soda, added to a solution of the salt, precipitate yellow hydrated binoxide of mercury; but a solution of lime decomposes it only partially, a deep red-coloured crystalline substance being thrown down, which is oxychloride of mercury. Ammonia throws down a white precipitate, which is called in the Pharmacopœia *hydrargyri ammonio-chloridum*.

Cyanogen and Mercury combine to form one compound, which is a bicyanide; it is prepared by boiling together in water, Prussian-blue and binoxide of mercury, which act upon each other though neither is soluble. By evaporating the solution the bicyanide is obtained in colourless crystals, the primary form of which is a right square prism; this salt has a metallic taste, is poisonous, much more soluble in hot than cold water, and but sparingly taken up by alcohol. By heat it is decomposed, and cyanogen gas is obtained. Nitric acid dissolves it without decomposition, but it is decomposed by sulphuric acid, and also by hydrochloric acid, which evolves hydrocyanic acid, with the formation of bichloride of mercury. The affinity between cyanogen and mercury is so strong, that its solution, unlike that of any other mercurial compound, is not decomposed by the alkalis; but hydrosulphuric acid and the hydrosulphates readily produce this effect. It is contained in the London Pharmacopœia.

Bicyanide of mercury is composed of

Two equivalents of cyanogen	52
One equivalent of mercury	202

Equivalent . 254

Fluorine and Mercury.—When hydrofluoric acid is added to a solution of protonitrate of mercury, no precipitation takes place, and it does not appear that a protofluoride of the metal has been yet obtained. If however the acid be added to binoxide of mercury, an orange-coloured compound is formed, which is soluble in water, and the solution by evaporation yields yellowish prismatic crystals, which appear to be perfluoride of mercury.

Bromine, the only elementary fluid known except mercury, unites with it to form two compounds.

Bromide or Protobromide of Mercury is procured by mixing solutions of bromide of potassium and protonitrate of mercury; a white curdy precipitate is obtained, which is insoluble in water.

Bibromide of Mercury is prepared by treating the metal with bromine and water. This salt is soluble in water, and the solution yields colourless crystals, which are dissolved by alcohol; this salt is decomposed by nitric and sulphuric acids. Neither of these salts is applied to any particular use.

SOLID COMBINATIONS.—*Non-metallic elementary solids and Mercury* mostly combine, but—

Carbon and Mercury do not form any compound.

Sulphur and Mercury unite in two proportions, forming the sulphuret or protosulphuret and the bi-sulphuret or persulphuret of mercury. When sulphur and mercury are triturated together they form a black mixture, which is used in medicine, and was formerly called *Æthiops mineral*; this however is not a definite compound of the elements.

Protosulphuret of Mercury is easily obtained by passing a current of hydrosulphuric acid gas into a solution of protonitrate of mercury; a black powder is precipitated, which is insoluble in water, totally volatilized at a high temperature, and is by nitric acid converted into a sulphate. It consists of—

One equivalent of sulphur	16
One equivalent of mercury	202

Equivalent 218

Bisulphuret of Mercury; Cinnabar; Vermilion.—It has been already stated that this is the principal ore of mercury. It is procured artificially by heating sulphur with eight times its weight of mercury in an iron vessel; the compound formed is then subjected to sublimation. The sublimate is a compact, deep red, crystalline mass, which, when reduced to powder, is of a beautiful scarlet colour; it is inodorous, insipid, insoluble in water, and unalterable by exposure to the air; it is totally vaporised by heat, and is decomposed when heated with some of the metals, and also by distillation with lime, potash, or soda.

When heated with sulphuric acid, sulphurous acid is evolved, and a sulphate of mercury is formed; it is insoluble either with sulphuric or hydrochloric acid, but when they are mixed, the nascent chlorine which is evolved decomposes and dissolves the bisulphuret, even without the assistance of heat.

Bisulphuret of mercury is composed of

Two equivalents of sulphur	32
One equivalent of mercury	202

Equivalent 234

Phosphorus and Mercury may be made to combine by heating phosphorus with the oxide or protosulphuret of mercury, by passing it in vapour over the protochloride, or phosphuretted hydrogen, into a solution of protonitrate of mercury. It is an insoluble substance, and has a black or brown appearance, which is modified by the mode of its preparation.

Iodine and Mercury form two compounds, and they may be formed in two modes: first, by the mere trituration of the equivalents with a little spirit of wine in a mortar; and secondly, by adding a solution of iodide of potassium to one of protonitrate of mercury to obtain the protiodide, and of pernitrate of mercury to prepare the biniodide. The former method is adopted in the Pharmacopœia.

Protiodide of Mercury is a greenish-yellow powder, devoid of smell, and insoluble in water. By the agency of light or of heat it is apt to be resolved into mercury and biniodide, but when quickly heated it sublimes unchanged.

Iodide or protiodide of mercury is composed of

One equivalent of iodine	126
One equivalent of mercury	202

Equivalent 328

Biniodide of Mercury, especially when prepared by precipitation, is of a fine red colour, approaching to scarlet; it fuses readily, and sublimes in rhombic scaly crystals, which are at first yellow, but become red on cooling. Water does not act upon it, but it is soluble in alcohol when heated, and also in some acids.

It is composed of

Two equivalents of iodine	252
One equivalent of mercury	202

Equivalent 454

Selenium and Mercury. The protoseleniuret is a tin-coloured compound, which sublimes in shining scales: the biseleniuret is obtained by fusing the protoseleniuret with selenium; it is a grey crystalline mass.

Metals and Mercury, or the greater number of them, readily combine; other metallic compounds are termed alloys, but those which contain mercury are called amalgams. [AMALGAMS.]

ACIDS AND MERCURY.—The action of acids on this metal, like that which they exert on others, is various, and of course depends upon the nature of the acid and the power of the metal in attracting oxygen.

Nitric Acid and Mercury.—It is a well-known fact that concentrated nitric acid acts upon very few metals, and it is curious that although the affinity between mercury and oxygen is extremely weak, yet this metal decomposes nitric acid and attracts its oxygen, even at common temperatures: the fluidity of the metal is probably the cause of this facility of action. A solution of pernitrate of mercury is thus obtained, which, if it crystallize at all, does so with great difficulty; for the solution may be evaporated to the sp. gr. 2.00 without yielding crystals.

Protonitrate of Mercury, that is, nitrate of the protoxide, is readily obtained by adding excess of the metal to the dilute acid. Action readily takes place, and crystals are formed with great readiness. There is no protoxide of any metal which forms so many nitrates as that of mercury; they are at present very imperfectly known, and require analysis.

The crystallized protonitrates of mercury are mostly decomposed by water, the protonitrate being precipitated in an insoluble state.

It has already been observed, that the pernitrate of mercury can scarcely be obtained in a crystalline form.

Hydrochloric Acid and Mercury do not act upon each other under any circumstances; when however the protoxide is added to the acid, protochloride of mercury and water are formed; while with the binoxide of mercury water and the bichloride are procured.

Sulphuric Acid and Mercury do not act on each other without the assistance of heat; with it, the acid is decomposed, and the metal converted into binoxide, and bipersulphate of mercury is formed.

Protosulphate of Mercury is procured by adding sulphuric acid or a sulphate to protonitrate of mercury; a white insoluble compound is precipitated, which is not applied to any use, and which consists of

One equivalent of sulphuric acid	40
One equivalent of protoxide of mercury	210

Equivalent 250

Bipersulphate of Mercury, obtained, as just described, by heating together the acid and metal, is a colourless salt, which, when mixed with water, is decomposed, and sulphuric acid remains in solution, while a yellow precipitate is obtained, formerly called *turpeth mineral*.

The bipersulphate of mercury is composed of

Two equivalents of sulphuric acid	80
One equivalent of binoxide of mercury	218

Equivalent 298

Turpeth mineral is a subsulphate of the binoxide of mercury, composed of

Three equivalents of sulphuric acid	120
Four equivalents of binoxide of mercury	872

Equivalent 992

Bipersulphate of mercury is not directly applied to any purpose, but the formation of it is one of the steps in the process of preparing calomel and corrosive sublimate in the Pharmacopœia.

Carbonic Acid and Mercury do not, under any circumstances, act on each other. When an alkaline carbonate is added to a solution of protonitrate of mercury, a precipitate is obtained, which, on drying, does not appear to contain any carbonic acid, so that a protocarbonate of mercury does not appear to be capable of being formed.

Percarbonate of Mercury may however be obtained by

mixing solutions of carbonate of soda and ~~pernitrate~~ of mercury; the precipitate, when dry, is of an ochre-yellow colour, and appears to be a dicarbonate, composed of

Two equivalents of binoxide of mercury	436
One equivalent of carbonic acid	22

Equivalent 458

Phosphoric Acid and Mercury.—The protophosphate is formed when phosphate of soda is added to a solution of protonitrate of mercury; a white crystalline precipitate falls, which is insoluble in water, or in excess of phosphoric acid; it is decomposed by heat, which expels the mercury and leaves the acid.

Perphosphate of Mercury is thrown down by phosphate of soda from the pernitrate; in appearance it does not differ much from the protophosphate, but, unlike it, is dissolved by excess of acid.

Fulminate of Mercury is a detonating compound, which was discovered by Mr. Howard; it is prepared in an indirect mode by dissolving mercury in nitric acid, and adding alcohol to the solution; when the effervescence is over, a greyish crystalline precipitate is obtained, which is to be washed with a small quantity of distilled water, and dried at a gentle heat.

The properties of fulminate of mercury are, that it explodes with considerable violence when heated to about 300°, and the explosion is accompanied with a bright flame; friction, the electric spark, sulphuric and nitric acids, also cause it to explode; the results of it are, azotic gas, carbonic acid gas, and a little ammonia. It appears to consist of

One equivalent of fulminic acid	34
One equivalent of protoxide of mercury	210

Equivalent 244

Acetate of Mercury.—The ~~protophosphate~~ is the only ~~one~~ which has been employed, and it is now indeed nearly fallen into disuse. It is prepared either by dissolving protoxide of mercury in acetic acid, or by mixing solutions of acetate of soda and protonitrate of mercury. This salt has a pearly lustre, is formed in crystalline flakes, dissolves sparingly in water, and is insoluble in alcohol. Its taste is acrid.

It is composed of

One equivalent of acetic acid	51
One equivalent of protoxide of mercury	210

Equivalent 261

SALTS.—Having now stated the nature and composition of the more important compounds of mercury, we shall state the general properties of its salts, which, according to Professor Brande, are as follows:—

The soluble salts of the protoxide are mostly white, of a metallic taste, and not virulently active as poisons. Some of them, when neutral, are resolved by water into basic and acid salts. Phosphorous and sulphurous acids, and protochloride of tin, precipitate metallic mercury: the caustic alkalis throw down a black powder; the carbonated alkalis, yellow or brown; the phosphates, white, even in very dilute solutions; sulphuretted hydrogen and the hydrosulphurets, black; hydriodic acid and the iodides, yellow; hydrochloric acid and the chlorides, white and curdy; the alkaline chromates, scarlet; ferrocyanide of potassium, white; the oxalates, white, even when very dilute; tincture of galls, brownish yellow.

The soluble salts of the peroxide or binoxide of mercury are mostly white when neutral, yellow when basic; they are poisonous, and nauseously metallic to the taste, and are often resolved by water into acid and basic salts. Copper throws down from them metallic mercury, and ammonia and carbonate of ammonia produce white precipitates; iodide of potassium, a scarlet-red; and infusion of galls, an orange precipitate. Unless in concentrated solution, they are not affected by hydrochloric or oxalic acids. The presence of organic substances interferes considerably with the appearances produced by some of the above tests; hence in cases of poisoning by corrosive sublimate peculiar precautions are sometimes required, and in all cases the precipitate should be collected and heated in a tube, if necessary, with a little white flux, or some reducing agent, so as to separate metallic mercury, the microscopic globules of which are easily sublimed and discerned. The insoluble

P. C., No. 925

mercurial salts are mostly volatilized at a red heat, and they are all decomposed, with the production of metallic mercury, when mixed with a little carbonaceous matter, and heated in a glass tube.

Uses of Mercury.—The uses of mercury in the arts are numerous and important. It is used in the extraction of gold and silver from their ores, in gilding [GILDING], the silvering of mirrors, and in filling thermometers and barometers. Bichloride of mercury has been lately extensively used for the prevention of dry-rot; and lastly this metal is extensively employed in various forms in medicine.

MEDICAL PROPERTIES OF MERCURY.—In a purely metallic state mercury, when taken into the human stomach, produces no effects except such as are owing to its mechanical properties. Nevertheless it may become oxidized, and, by combining with some of the acids of the stomach, occasion violent disorder. Even its external application leads to similar results, from the metal first becoming oxidized, then absorbed, and producing the same effects as if taken by the mouth. The preparations of mercury differ very much in the degree of their action, both according to the nature of the combination, and also of the dose employed or the mode of administration. The milder preparations seem only to increase the natural and healthy actions of the organs of the body, particularly the secreting and exhaling organs; while the more active, if not given in very minute doses, destroy the texture and impair the function of many organs, both those with which they are brought into immediate contact, and others which they affect by sympathy or other means. No medicinal substance is capable of producing so much benefit, none is so frequently abused, or so fertile a source of injury, as mercury. Its mode of action is little understood, but its effects are often sufficiently obvious. A brief statement of the most important of these effects is all that can be given here.

When mercury is mixed with chalk or magnesia, or with confection of roses (which is the case when it is made into *blue pill*), is taken in moderate dose into the stomach, it does not seem to make any immediate sensible impression, unless that organ be in a state of morbid sensibility, when it is apt to cause heartburn, nausea, or disturbance of the bowels. It may be repeated at longer intervals, and the individual, especially if robust, appears to have an increased appetite and more ready digestion. This is more particularly the case when corrosive sublimate (bichloride of mercury) is given in very minute doses. Even the introduction of mercury into the body by friction over parts where the skin is thin, would seem to increase, for a time, the activity of the whole system. To whatever surface applied, the absorbents would appear to lay hold of it, and carry it into the circulating mass. Owing to peculiarity of constitution (idiosyncrasy) a very minute quantity of mercury produces in some individuals very striking effects, either violent salivation, disturbance of the bowels, or other inconveniences, accompanied by great debility. This result is quite distinct from the effects of an overdose of some of the more active forms, which produces actual poisoning, or from the effects of the too long continued administration of some of the mild preparations. Children, owing to the irritability of their bowels, are not so apt to be salivated as adults, and more mercury can be borne in warm than in cold countries.

When a single dose of mercury is given, it is generally one of the preparations which act on the bowels, either alone, or in combination with or followed by some other purgative medicine; and little permanent effect is observed: but repeated small doses, especially if hindered from passing off by the bowels, by combination with opium, excite arterial commotion, and end by establishing a febrile movement. The pulse is full and more frequent, the animal heat augmented, the secretion from the skin abundant; at last followed by thirst, restlessness, and sleeplessness. This disturbance frequently lasts some time, even after the medicine has been discontinued, and is occasionally accompanied with determination or congestion of blood either towards the lungs, abdomen, or brain, followed sometimes by hæmorrhage from various organs. Blood drawn during a mercurial course is generally found covered with a buffy coat, the same as is the case in inflammatory diseases. On the salivary glands the effects are most conspicuous: they become irritated, more sensible, turgid, and pour out abundant

VOL. XV.—P

saliva, which, on standing, deposits flakes of coagulated albumen. The breath at the same time acquires a peculiar fetor (called mercurial), the gums are swollen, but pale and tender, the teeth become loose, and the tongue and lining membrane of the mouth are covered with ulcers.

The general commotion of the system often proves a powerful agent in the cure of many diseases, but occasionally it becomes too great, and requires to be moderated. Not only must the exhibition of the mercury be suspended for a time, in such cases, but very plethoric persons must be bled, and put on the antiphlogistic plan even before beginning its use. The warm bath, diluent drinks, and a milk or farinaceous diet, with cool air, are proper means of lessening the violence of its action.

The effects just mentioned show the necessity of abstaining from its administration when there is a tendency to hæmorrhage (especially of the lungs), or a disposition to consumption, or if there exist a scrophulous constitution, or the person be affected with sea scurvy: also during certain states of the female system, and during pregnancy or suckling.

When the use of mercury is too long continued, or it is given in too strong doses, its stimulating action appears to fatigue the system, and to pervert the function of assimilation, both immediately in the blood, and also in the different organs and tissues. Hence the individual loses his muscular power, becomes pale, tumid, and puffy, or else greatly emaciated. The brain and spinal chord are irritated; the limbs exhibit involuntary tremblings, and all the tissues acquire a morbid susceptibility. The blood is found to be deteriorated, and to have lost its ordinary consistence, and the person appears to be affected with scurvy or consumption. The inconsiderate use of mercurial preparations, especially of corrosive sublimate, often occasions chronic inflammation of the stomach, causing indigestion, and alterations or thickenings of the coats of the stomach. Diseases of the brain not unfrequently result from an improper use of mercury. Lastly, a peculiar affection of the skin often occurs from the abuse of this substance.

In the treatment of diseases, four distinct effects may be obtained from the employment of mercurial preparations. 1st. By some of them the intestinal canal is irritated, and the expulsion of its contents occasioned. 2nd. Others are used to produce a general commotion of the system, to rouse the lymphatics, and excite both the secreting and excretory glands. 3rd. To control or altogether change the action of the capillary vessels, when that is extreme, and tending to the effusion of serum, and more especially of coagulable lymph. With this may perhaps be joined the action of the mercury as an alterative. 4th. What is regarded as its specific effect in bringing about the cure of some peculiar diseases.

Calomel, or the protochloride of mercury, is the preparation most employed as a purgative; it influences the intestinal canal along its whole length, and excites the liver and other glands to secretion. It is of very great utility, not only at the commencement of fevers, but even during their course, either when given alone or in conjunction with some other purgative. It is not admissible if the tongue be very red and sensible, and a similar state of stomach be presumed to exist. In many eruptive fevers, especially scarlet fever, its early and even free employment is productive of the best results. In the yellow and many other fevers of hot climates it is indispensable. In these diseases mercury is introduced into the system by every means; and whenever the patient is salivated, recovery may be expected. In many of the less rapid fevers of Europe, the like benefit follows its use.

During the inflammatory and turgescient stage of hydrocephalus acutus, or water on the brain, calomel, alone or with digitalis, is frequently efficacious in saving the patient; at the same time other forms of mercury, especially the liniment, may be used. In the wasting or atrophy of children, the steady daily use of calomel and rhubarb produces the best results, if proper dietetical means be adopted.

These measures should at no time be resorted to, except under the direction of responsible medical attendants. The unnecessary use of mercury, when some other purgative would have answered as well, is much to be reprobated, and not only injures the constitution of children, but if they are teething at the time, it leads to the early decay of their teeth. (Bell On the Teeth.)

Persons under the influence of mercury, even when a single dose has been taken as a purgative, are very liable to take cold, especially from wet. This must be carefully guarded against. The bichloride of mercury (or corrosive sublimate) seems not to dispose the system so much to be hurtfully impressed by cold, and is therefore well suited to camp and navy practice. Besides, if given in sufficiently small doses, it is perhaps the best of all the preparations to use as an alterative, especially in cases of chronic inflammation or thickening of the tissues, such as the heart.

Mercury has a great power of checking the deposition of coagulable lymph, and controlling changes in the organic particles of bodies, both vegetable and animal. One of the most valuable uses of mercury is connected with this power of changing the action of the capillaries when that action is extreme, or when there is a tendency to pour out serum in excess, or effuse coagulable lymph. In some inflammations the action of the vessels is so violent as to pour out their contents, and this leads to obstructions or changes of structure which derange the functions, or even speedily occasion death. Thus in croup coagulable lymph is effused in the windpipe, obstructing respiration; in peritonitis, or inflammation of the outer lining of the intestines, lymph is poured out, agglutinating the folds of the intestines; in iritis the same happens, closing the pupil of the eye and destroying vision. In all these cases, after free venesection, or even without it, calomel given very freely will hinder further effusion, and even cause the absorption of what has already escaped from the vessels; as may often be seen when the iris of the eye is inflamed.

Many serious chronic diseases are removed by a judicious and persevering use of mercury, but these can neither be enumerated here, nor can even the most general rules be attempted to be laid down. (Holland, *Medical Notes*; On *Mercurial Medicines*; and Teale *On Neuralgic Diseases*.)

The specific employment of mercury is still less suitable to be discussed here. It may be remarked however that the opinion for the necessity of strong mercury in any quantity is now altogether exploded.

It is not necessary to dwell on any of the other preparations of mercury, many of which are valuable, either alone or as additions to other substances. Calomel frequently greatly assists in promoting the action of other medicines, particularly diuretic medicaments. How far calomel, either in small frequently repeated doses or in very large ones, was really useful in Asiatic cholera cannot be ascertained. The employment of corrosive sublimate in the arts depends in some cases on principles explained above. Thus it checks fermentation, and opposes the formation of new compounds; hence, when applied in solution to timber, it prevents the dry-rot from occurring, by solidifying the albumen of the wood. [ANTISEPTICS.] In cases of poisoning by it, the antidotes most proper are those substances which contain albumen, such as white of egg, milk, flour, &c. [ALBUMEN.]

MERCURY, the planet nearest to the sun. Its orbit being entirely within that of the earth, it never recedes to the point of the heavens opposite to the sun, but is always found within 29° of the sun. Hence it is only visible to the naked eye in the evening, when it is to the east of the sun, and near to its greatest distance (or elongation) from the sun; so that the sun can descend sufficiently below the horizon to allow the planet to be seen just before its setting: similarly, it is only visible in the morning (before sunrise), when it is near its greatest elongation westward of the sun. The phases of Mercury are not visible without a telescope. The apparent diameter of Mercury varies from 5 to 12 seconds; the real diameter is .398 of that of the earth, or about 3140 miles. Its bulk is to that of the earth as 63 to 1000; its mass is reckoned at the two-millionth part of that of the sun. It revolves on an axis, the inclination of which to the ecliptic is not determined, in 24^h 5^m 28^s.3. It has seven times the light and heat of the earth.

The transits of Mercury, or passages of the planet over the sun's disc, take place when the conjunction (the inferior conjunction, as it is called, Mercury being between the earth and the sun) happens at the time that the planet is near its node. These transits are not so useful in the determination of the sun's parallax or the longitude of the place of observation as those of Venus: we shall therefore refer the account of such transits in general to the latter planet. The following are, according to Delambre, the times of the

transits which will yet take place in the present century (civil time at Paris):—

1845	8 May, 8 P.M.	1878	6 May, 7 P.M.
1848	9 Nov., 8 P.M.	1881	8 Nov., 1 A.M.]
1861	12 Nov., 7½ A.M.	1891	10 May, 3 A.M.]
1868	5 Nov., 7 A.M.	1894	10 Nov., 6½ P.M.]

Elements of the Orbit of Mercury.

Epoch, 1799, December 31, 12^h mean astronomical time at Seeberg.

Semixis major ·3870938, that of the earth being assumed as the unit.

Excentricity ·2041704; its secular increase (or increase in 100 years) ·0000039.

Inclination of the orbit to the ecliptic 7° 0' 5"·9; its secular increase 18"·4.

Longitudes from the mean equinox of the epoch: (1.) of the ascending node, 45° 57' 9"·0; its secular increase (combined with the precession), 4215"·1; (2.) of the perihelion, 74° 20' 6"·0; its secular increase (combined with the precession), 5602"·9; (3.) of the planet (mean), 108° 4' 48"·3.

Mean sidereal motion in one mean solar day, 4° 5' 32"·558; in 365½ it is 53° 42' 47"·65 more than 4 complete revolutions; sidereal revolution, 87·96926 mean solar days.

MERCURY, TRANSIT OF. [MERCURY; VENUS, TRANSIT OF.]

MERGANINÆ (*Merginæ*, Bonap.), a subfamily of *Anatidæ*, consisting of the genus *Mergus*, Linn., the *Goosanders* or *Mergansers* of the British. The Prince of Musignano makes it include two subgenera, *Mergus* (*Smew*) and *Merganser*, Leach (*The Goosanders*), and places the subfamily next to the *Fuligulinæ*, and immediately preceding the *Pelecanidæ*. The Linnean genus *Mergus* is placed between the last section (*Cristatæ*) of the great genus *Alca* and the genus *Alca* in the *Systema Naturæ*, and the position assigned to it by various authors will be found in the article *Alca*. In the second volume of Mr. Swainson's *Classification of Birds*, the subfamily is placed after the *Fuligulinæ*, and immediately preceding the family *Colymbidæ*.

Bill of Merganser.

Foot of Merganser.

Generic Character.—Bill straight, narrow, and slender, subcylindrical anteriorly, wide at the base, and abruptly hooked at the tip; margins of both mandibles serrated, the serrations or teeth directed backwards. *Tongue* slender. Feet short, with the toes fully palmated, and placed behind the point of equilibrium.

The species are not numerous, and of these, *Mergi*

Merganser, *Serrator*, *albellus*, and *cucullatus* are found in Europe. We select *M. Merganser* and *M. albellus* as examples.

Merganser. (Leach.)

Example, *Merganser Castor* (*Mergus Merganser* and *Castor* of Linnæus).

Description.—*Very Old Male.* Tufted head (the tuft large and thick), and part of the neck greenish black, the reflection varying in different lights; lower part of the neck, breast, belly, abdomen, coverts of the wings and scapulars farthest from the body, tinged of a yellowish rose colour* (which soon fades in stuffed specimens to white) on the under parts; upper part of the back and scapulars nearest to the body deep black; quills blackish; great coverts bordered with black; rest of the back and tail ash-coloured; beauty-spot on the wing white, without transverse bands; bill deep red, black above and on the terminal nail; iris reddish brown, sometimes red; feet vermilion red. Length 26 to 28 inches. (Temm.)

In this plumage the bird is the *Mergus Merganser* of Linnæus and others; *Le Harle* of Buffon and the French; the *Goosander* or *Merganser* of Latham and Pennant; *Gansen-säger* and *Taucher-gans* of Bechstein and the Germans; *Mergo*, *Oca marina* e *Mergo dominicano* of the Stor. degl. Ucc., and *Dubbelde Zaagbek* of Sepp. and the Netherlanders.

Female.—Tuft long and loose; head and part of the neck reddish brown; throat pure white; lower part of the neck, breast, sides, and thighs whitish ash; all the upper parts deep ash; beauty-spot of the wing white without any transverse band; bill faded red; iris brown; feet yellowish red, webs ashy-red. Length 24 or 25 inches.

Young Males of the Year: Similar to the females.

The Young at the age of one year are distinguished by blackish spots disposed on the white of the neck; the ruddy colour of the throat is terminated by a deeper colour; blackish plumes begin to show themselves on the top of the head, and white feathers appear on the coverts of the wings.

In this state the bird is the *Mergus Castor* of Linnæus and others; *Mergus rubricapillus* of Gmelin; the *Harle femelle* of Buffon; the *Dun Diver* or *Swamp Poul* of Latham and others; and the *Mergo oca* of Stor. degl. Ucc.

This species is the *Sugherone* of the Italians; the *Meer-rack* and *See-Rack* of the Germans; *Wrakfogel*, *Kjorkfogel*, *Ard*, and *Skraka* of the *Fauna Suecica*; *Skallesluger* of the Danes; *Skior-and* of the Icelanders; *Peksok* of the Greenlanders; *Seek* of the Cree Indians; *Hwyad dlanhedog* of the ancient British; and *Goosander* and (provincial) *Jack saw* of the modern British. It is supposed to be the *Káσtopos όρνις*, of the Greeks, the *Fiber* and *Castor Ales* of the Latins, and is the *Bieure* of the old French.

Food; Reproduction; Utility to Man.—The food of the Goosander consists of small fish, amphibious animals, small crustaceans and mollusks. Temminck says that its nest is placed among rolled pebbles on the banks of waters, in bushes or in hollow trees, and that it lays twelve or fourteen whitish eggs, which are nearly equally pointed at each end. The flesh is very rank and bad. Graves, who tasted one, pronounces it to have been offensive in the highest degree. The old French quatrain, in the *Portraits des Oyseaux*, gives the following description of its habits and of its quality as food:—

Le Bieure sealt aux estangs se plonger
Pour le poisson, auquel est dommagable.
Mais qui voudroit festoyer un diable,
Fauldroit un Bieure avoir pour son manger.

Geographical Distribution.—Mr. Gould (*Birds of Europe*) states that 'its native locality appears to be the northern regions of the continents of Europe and America, where, among large and unfrequented lakes, it finds an asylum and breeding-place; from these, its summer haunts, it emigrates southwards on the approach of the severities of winter, seldom appearing in our latitudes unless the season indicates an exceedingly low temperature in the Arctic circle: at such times it frequents our shores and unfrozen lakes, either in pairs or in small flocks of seven or eight: but the extensive inland waters of Holland and Germany appear to

* The under plumage of the specimen described by Dr. Richardson had the under plumage rich buff orange, which faded to white.

be its favourite resort.' This species was shot at Fulham in the severe winter of 1837. It appears in Dr. Richardson's list of birds, that they merely winter in Pennsylvania and migrate in summer to rear their young in the fur countries; the specimen described by him was killed in the Saskatchewan. It also occurs in Major Sabine's list of Greenland Birds. The Prince of Musignano notes it as rather rare in winter at Rome, and as not common, at the same season, in Philadelphia (*Specchio Comparativo*), and as occurring in Europe generally, and in America generally, in his *Geographical and Comparative List of the Birds of Europe and North America*. It was seen in Japan by Dr. Von Siebold and M. Bürger.

The Goosander, *Mergus Merganser*, Linn.).
Lower figure, male; upper figure female.

Mergus.

Ex. *Mergus albellus*.

Description. *Old Male.* A great spot of greenish black on each side of the bill, a similar coloured but longitudinal one on the occiput; the tufted crest, neck, scapulars, small coverts of the wings, and all the lower parts very pure white; upper part of the back, the two crescents which are directed under the sides of the breast, and the edges of the scapulars, deep black; tail ash-coloured; sides and thighs varied with ash-coloured zig-zags; bill, legs (tarsi), and toes bluish-ash; webs black; iris brown. Length 15 to 16 inches.

In this state the bird is *Mergus albellus* of Linnæus and others; *Le petit Harle huppé ou la Piette* of Buffon; the *Weiser Säger* of Bechstein and others; the *Witte non Duiker* of Sepp.; the *Mergo Oca minore* of the 'Stor. degl. Ucc.,' and the Smew or White Nun of the English ornithologists.

Female.—Summit of the head, checks, and occiput reddish brown; throat, upper part of the neck, belly, and abdomen white; lower part of the neck, breast, sides, and rump bright ash; upper parts and tail deep ash; wings variegated with white, ash, and black. Length 15 inches.

Young of the year, similar to the female.

Males at the Age of One Year.—These are distinguished by the small blackish feathers which form the great spot at the side of the bill; by some whitish and white feathers scattered on the head; by the upper part of the back, which is variegated with black and ash-coloured feathers; and by indications of the two black crescents on the side of the breast. The young of both sexes have the great coverts of the wings terminated by a large white space, while the old ones have no white there except at the point.

The females and young of the year are the *Mergus minutus*, Linn.; *Mergus Asiaticus*, Gm.; *Mergus stellatus*, Brunn.; *Mergus Pannonicus*, Scop.; *La Piette femelle*, Buff.; *Le Harle étoilé* (young male), Buff.; *Mergo Oca minore* (female), and *Mergo Oca cenerino* (young male of the year), 'Stor. degl. Ucc.;' *De Kleine Zaagbek* (young of the year), Sepp.; and *Red-headed Smew* (young male in moult), Penn., 'Brit. Zool.'

This species is the *Kreutz-Ente* of Frisch and the Germans; the *Hviid Side* of the Danes; *Sugherone occhialino* of the Italians; *Lleian wen* of the ancient British; Smew and (provincial) White Nun, Vane Widgeon and Smec of the modern British.

Food; Reproduction; Utility to Man.—The food of the Smew consists of small crustaceans, water-insects, mollusks, little fish, and water-plants. The nest, according to M. Temminck, is placed on the borders of rivers and lakes, and the number of eggs amounts to twelve; they are whitish. The bird is in no request for the table.

Geographical Distribution.—The countries of the Arctic circle in both worlds; migratory in autumn, but especially in winter, in England, Holland, France, and as far as Italy; rather abundant in Holland on the lakes and marshes (Temminck). It is seldom seen in Britain except in inclement winters. The species was not observed by Dr. Richardson, but it is noted by him in the tables compiled from the *Specchio Comparativo* as one of the birds that migrate northwards from or through Pennsylvania in spring, and may therefore be considered as returning to the fur countries to breed. The Prince of Musignano notices it as rather common in winter, particularly the young, near Rome, and as very rare and adventitious at Philadelphia (*Specchio Comparativo*). The same author, in his *Geographical and Comparative List*, notes it as occurring in Europe generally and on the northern and central coasts of America. Dr. Von Siebold and M. Bürger found it in Japan.

Mergus albellus: upper figure, male; lower figure, female. (Gould.)

M. Temminck remarks that the *Harles*, or birds of this subfamily, live upon the waters, where they swim, having generally the whole of the body submerged, and only the head out of the water.* They dive easily and often, swim with extreme agility *entre deux eaux*, and use their wings to assist them in this sort of natation. They remain long on wing, and fly very swiftly. Their walk is very vacillating and embarrassed, their legs or feet, as well as those of the sea-ducks, being more withdrawn within the abdomen than those of the ducks which have the posterior toe smooth. Their food consists principally of fish and amphibious animals, and of the first they make great destruction. In temperate climates they are only seen in winter; their habitual dwelling is in cold countries, where they breed. They are much wilder than the different species of ducks, and have not been domesticated. They moult once a year; but the old males, like those of the ducks, moult in the spring, whilst the old females and the young moult in the autumn. The young males, before their first or second moult, hardly differ at all from the females.

MERGER. It is somewhat difficult to give an exact definition of this legal term. In order to form an accurate notion of what is meant by it, the notion of the legal term estate [ESTATE] is a necessary preliminary. 'The accession of one estate to another, or more accurately speaking, the circumstance that two estates immediately expectant on each other, meet or are united in the same person, is the cause of the merger.' (Preston.) These words express in

* The Smew does not swim with the body submerged and only the head out of the water; but with a very fair portion of its body above the surface.

general terms the conditions necessary in order that merger may follow as a consequence. This consequence, called merger, is that the preceding estate ceases to exist, and the estate in which this preceding estate is said to be merged continues to be exactly the same as it was before that union which was the cause of merger.

It is necessary to add to this general description of the cause of merger, that the estate which is prior in point of time must not be greater (in legal estimation) than the estate which immediately follows: it may be either equal or less, but not greater. Also, the estates must both be vested estates, and both must be legal or both equitable estates.

Thus, if A is tenant for life, with reversion to B in fee, and A surrenders his estate to B, or B releases his estate to A, in either case the life-estate is merged, the consequence of which is that the estate in reversion immediately becomes a fee in possession. It seems that one term of years will merge in another, and a larger term in a less; at least this is the case when the second term is a term in reversion. Thus, if A is tenant for years, with reversion to B for years, and A surrenders or assigns his term to B, the term which belonged to A is merged. There is one exception to this rule: if the estate of A is derived from the estate of B as an underlease, the original term of B is not abridged by such merger. In fact, merger, in the proper sense of the term, can never apply to a surrender or assignment of an estate in land to the person by whom, and out of whose larger estate, that smaller estate was granted. But if A, who is seised in fee, leases first to B for five hundred years, and then to C for ten years, by way of immediate reversion, and C assigns his term to B, the estate of B is merged in that of C, which becomes an estate in possession, and can have no longer duration than ten years. Opinions vary as to the question whether a term can merge in a term, remainder.

Estates tail are not subject to merger; an exception which is a necessary consequence of the form of the gift to the heirs in tail, so long as there are any. Formerly, if an estate tail had become a base fee by the tenant in tail levying a fine, such base fee would merge by union with the immediate reversion in fee. But by a recent statute (3 and 4 Wm. IV., c. 74), such base fee will not merge in the reversion in fee, but shall be 'enlarged into as large an estate as the tenant in tail, with the consent of the protector, if any, might have created by any disposition under this act, if such remainder or reversion had vested in any other person.'

If the two estates, the union of which in one person might otherwise cause merger, do not unite in him in the same right, there is no merger.

The various exceptions to the general principles of merger are numerous enough to form the subject of an entire treatise. The whole subject is discussed at great length in the third volume of Mr. Preston's *Treatise on Conveyancing*.

The origin of the doctrine of merger is uncertain, and no hypothesis seems fully to explain all the cases of merger as now settled. In the case put by Bracton (fol. 12), the termor for years who had become the feoffee of the land, is considered as having, by the acceptance of the freehold, renounced the term (ex quo idem B se tenuit ad feoffamentum, tacite termino renuntiavit). The origin of merger is discussed in Preston's third volume, chap. iii., &c.

MERGUI. [TENASSERIM.]

MERGULUS. [Auk, vol. iii., p. 100.] The Prince of Musignano notes the *Little Auk* (*Mergulus Alle*) as occurring in the northern and central parts of Europe, and on the northern shores of America. (*Geographical and Comparative List*.)

MERGUS. [MERGANINÆ.]

MERIAN, MARIA SIBYLLA, the daughter of Matthew Merian, an eminent Dutch engraver, was born at Frankfort-on-the-Mayn, April 12, 1647. Her instructor in drawing was Abraham Mignon. In 1665 she married John Andriez Graff, a painter of Nürnberg, but the celebrity which attached to her own name as an artist prevented that of her husband from being adopted. They had two children, both daughters, who were also skilled in drawing. In consequence of liberal offers Madame Merian and her husband settled in Holland, but Maria Sibylla, whose great object was the study of nature, travelled for the sake of delineat-

ing insects, flowers, and other natural objects. In 1699 she went to Surinam for the express purpose of making the drawings which have since added so considerably to her fame, and remained there till the month of June, 1701.

She published—1, 'The Origin of Caterpillars, their Nourishment and Changes,' in Dutch, 2 vols. 4to., the first published at Nürnberg in 1679, the second in 1683, published in Amsterdam in Latin, 4to., 1717. This work, much enlarged by herself and her daughters, was published in French by John Marret, fol., Amst., 1730, under the title of 'Histoire Générale des Insectes de l'Europe.' 2, 'Dissertatio de Generatione et Metamorphosis Insectorum Surinamensium,' fol., Amst., 1705, separately in Dutch and in Latin. These editions contain only sixty plates. To some of the later ones twelve plates were annexed by her daughters Jane Helen and Dorothea Maria Henrietta. There is an edition of this work in folio, French and Dutch, printed at Amsterdam in 1719; another in French and Latin, Hagæ, 1726; and another in Dutch in 1730. There have been also editions of the two works united, under the title of 'Histoire des Insectes de l'Europe et de l'Amerique,' fol., Par., 1768 and 1771.

Madame Merian died at Amsterdam, January 13, 1717. Many of the original drawings of this artist are preserved in the department of drawings and prints in the British Museum, in two volumes, purchased by Sir Hans Sloane at a large price. One contains the insects of Surinam, the other those of Europe. A few of the Surinam insects, though elegantly finished, appear, upon examination, not to be entirely drawings, but to have been coloured upon outline proofs of the engravings. Those of Europe are entirely original delineations. All are upon vellum. Other drawings of Madame Merian are preserved at Petersburg, in several collections in Holland, and at Frankfort. A portrait of Madame Merian, formerly Sir Hans Sloane's, is still preserved in the British Museum. An engraved portrait of her, by Houbraken, is prefixed to the Latin edition of the 'Origin of Caterpillars,' 1717.

(*Biog. Universelle*, vol. xviii., pp. 366, 367; Brunet, *Manuel du Libraire*, 8vo., 1820, tom. ii., pp. 475, 476; Chalmers, *Biogr. Dict.*, vol. xxii., p. 72.)

ME'RIDA, a town of Extremadura, in Spain, in 38° 48' N. lat. and 6° 15' W. long. It was founded by Publius Casirius, a Roman general under the emperor Augustus, from whom it was named Emerita Augusta. It was subsequently made the capital of the province of Lusitania (which included nearly the whole of Portugal, with part of Leon, Extremadura, and Old Castile), and was the largest and most magnificent city in Roman Spain. From the hands of the Romans it passed into those of the Goths, who made it an archiepiscopal see. In the year 587 it was the focus of a plot formed by the Arians to kill the reigning monarch and extirpate the Catholic religion from the land. It was also the seat of several provincial councils, of which that of A.D. 666 is the most known. On the invasion of the Arabs in 711 it offered a stout resistance, but was eventually obliged to capitulate to Muza, who on entering the city was amazed at its vast size and the grandeur of its buildings. According to a Moslem chronicler it was then eight miles in circumference, and was garrisoned by 90,000 men. By the Arabs its original name was corrupted into Mérida. In 1230 it opened its gates to the Christian king Alonso XI. of Castile and Leon, after a great battle, in which, aided by the apostle James and other saints in white robes (as tradition has it), he routed a greatly superior force of Moors, headed by their king Ibn Hud. Alonso, to testify his gratitude, entrusted the government of the city to the military order of St. James, in whose hands it has till recently remained.

Modern Mérida is one of the most decayed and poverty-stricken towns in the Peninsula. In extent it has shrunk to a very small compass; its population has dwindled to less than 5000; and the trade in merino wool, of which it has long been the depôt, is rapidly declining. It is situated on the right bank of the Guadiana, on a rising ground, in the midst of an open and gently undulating country, naturally very fertile, but almost uncultivated, and in summer rendered very unhealthy by malaria. The sole interest of modern Mérida lies in its numerous remains of Roman magnificence. The houses, churches, walls, and pavements, abound in Roman fragments, columns, inscriptive tablets, altars, vases, statues, and bas-reliefs. In the fields, gardens,

and roads without the town, similar remains are found. But the principal ruins are an amphitheatre almost entire, which by letting in the waters of the Guadiana could at pleasure be turned into a naumachia; a circus, said to equal in size the Circus Maximus at Rome; a theatre, where in modern times bull-fights have been held; the shell of a lofty triumphal arch, now stripped of its ornaments; some baths in excellent preservation, and a gateway defaced by Arabic inscriptions. Encased in a private house is a small peripteral temple of Mars; the capitals as well as shafts of the columns are of granite. There are also two Roman bridges; one of enormous length and curious construction, with a fortress at one end. Near the town are the ruins of two grand aqueducts built of brick and granite mixed. Of the latter material are constructed all the ancient edifices of Mérida, with very trifling exceptions.

At the distance from Mérida of one and two leagues respectively are two remarkable reservoirs, by some considered of Roman, by others of Moorish architecture. The first, called Albufera, is about 100 feet in length by nearly 60 feet in depth, enclosed by thick walls, with two fine towers. The other, called Albucra, is smaller, but its walls and the single tower which surmounts them are much finer.

(Mariana, *Historia General de España*; Conde, *Historia de los Arabes*; Ponz, *Viage de España*; Laborde, *Itinéraire Descriptif de l'Espagne*; Semple's *Journey through Spain and Italy*; Captain Cook's *Sketches in Spain*.)

MERIDIAN (*meridies*, mid-day). In the heavens the meridian is the circle which passes through the pole and the zenith of the spectator: on the earth it is the circle which passes through the pole and the spectator's position; consequently the terrestrial meridian is the section of the earth made by the plane of the celestial meridian.

The circle derives its name from being that on which the centre of the sun is found at mid-day, or real noon. In the case of a fixed star, the time at which its altitude is greatest is the moment of its coming on the meridian; but in that of the sun or a planet, the orbital motion prevents the moment of its culmination (or coming on the meridian) from being exactly that of its attaining its highest point; though the difference is not worth noting for ordinary purposes. [See DOCTRINE OF THE.]

MER [SHEEP.]

MERIONES [MURIDÆ.]

MERIONETHSHIRE, a county of North Wales, bounded on the north by Caernarvonshire and Denbighshire, on the north-east by Denbighshire, on the east and south-east by Montgomeryshire, on the south by Cardiganshire, and on the south-west and west by Cardigan Bay, an inlet of the Irish Sea. Its form approximates to that of a right angled triangle, having two sides facing the north and west respectively, and the hypotenuse facing the south-east.

The area of the county is estimated at 666 square miles; it is the sixth of the Welsh counties in respect of size, being a little smaller than Cardiganshire, but larger than Denbighshire. The population in 1821 was 34,382; in 1831 it was 35,315, showing an increase of 118 persons only, and giving 53 inhabitants to a square mile. In absolute population it is inferior to all the Welsh counties except Radnorshire; and in density of population is inferior even to that. Bala and Dolgelly are the assize towns: the county election for members of parliament takes place at Harlech. Bala, the nearest of these places to London, is in 52° 55' N. lat. and 3° 34' W. long., about 180 miles in a direct line north-west of London, or 194 miles by the Holyhead parliamentary road to Shrewsbury, and from thence through Llangynnog.

Coast Line.—The northern part of the coast is formed by the estuary of which the Traeth Mawr and the Traeth Bach are portions. The Traeth Mawr (of which a considerable part has been recovered from the sea by an embankment about a mile in length, reaching across this branch of the estuary from side to side) forms the boundary between Caernarvonshire and Merionethshire. The Traeth Bach or Bychan belongs entirely to the latter: it comprehends many thousand acres, and receives the rivers Fellnrhyd, or Bychan, and Dwyryd. This arm of the estuary penetrates several miles inland, becoming narrow as it proceeds. It is dry at low water, except a narrow channel in the centre, through which the united streams find their way into the sea, and is crossed by a ferry.

From the Traeth Bach the coast runs south about six miles past Harlech to the little headland on which stands the village of Mochraes or Mochras. From the Traeth Bach to the town of Harlech the immediate neighbourhood of the sea is low and marshy. Between Harlech and Mochraes it rises into cliffs. It is skirted by sands dry at low water, and at some distance out to sea are three sand-banks, the 'Dutch Bank,' the 'Pontigal Bank,' and the 'Sarn Badrig' (St. Patrick's Causeway) or 'Sarn Badrhwyg' (Ship-breaking Causeway). This remarkable shoal runs from the immediate neighbourhood of the coast 22 miles out to sea in a south-west direction; it is composed of sand and gravel. It is dry at the ebb in spring tides, and in storms is marked by fearful breakers. Tradition says that this part of the sea was once inhabited land called Cantrér Gwaelod, or the Lowland hundred, and that it was overwhelmed by the sea about the close of the fifth century. (Ponant.) The name, St. Patrick's Causeway, is said to have originated from a monkish legend, that it was formed by St. Patrick in order that he might pass from Ireland to Britain.

From Mochraes the coast runs south-south-east eight miles to the river Maw, at the mouth of which stands the town of Aber-Maw, contracted into Ber-Maw or Barmouth. Throughout Merionethshire, north of the Maw, the coast is skirted by sands of greater or less breadth. From the Maw the coast runs southward 14 miles to the wide estuary of the Dovey, taking a circuit convex to the sea, and rising into cliffs midway between the rivers. At the southern extremity of these cliffs the river Towy, or Disynwy, flows into the sea. Between the Towy and the Dovey the coast is again skirted by sands. The whole extent of the Merionethshire coast is about 38 miles, following its principal bends.

Surface and Geological Character.—Merionethshire is the most mountainous of all the Welsh counties, and contains some of the loftiest peaks in North Wales; there are however no peaks so high nor precipices so abrupt as those of Caernarvonshire. The principal mountain-chain is that which, in one part at least, is called the mountains of Berwyn, and which traverses the county from north-east to south-west, skirting the valleys of the Dee, the Wnion, and the Maw. The principal summits of this chain are, Cader Berwyn or Ferwyn, on the border of this county and Montgomeryshire, seven miles south of Corwen, 2563 feet above the level of the sea; Arran Fowddy, near the Wnion, above Dolgelly, 2955 feet; Pen-y-Gadair (summit of Cader Idris), three miles south-west of Dolgelly, 2914 feet; and Pengarn, at the extremity of the chain near the sea, 1510 feet. West of Bala, and near the centre of the county, is a group of mountains, of which Arrenig Mawr is the highest point, 2809 feet above the level of the sea. From this central group branches run westward to the sea in the neighbourhood of Harlech, and north-westward to join the group of Snowdon. There are no plains.

The county is almost entirely occupied with the slate rocks which predominate in North Wales. Along the valley of the Dee, as far up as Bala and the valley of the Alwen, a bluish-grey limestone is found, which is quarried for lime, the principal manure employed in the county. Great quantities of white limestone are quarried and burnt for lime near Corwen. This limestone is surrounded on every side by primitive argillaceous slate, which occupies all the eastern side of the county, as far as a line drawn from Bala, north-west along the vale of the Trewern, and southward along the Twrch and the Dovey to Dinas-y-Mowddy. The slates of this formation are quarried in the neighbourhood of Corwen.

Westward of the line described the rocks are chiefly slaty, forming abrupt and rugged mountains of desolate appearance. Lead and copper mines are worked near Towyn at the mouth of the Disynwy, and copper-mines in the neighbourhood of Barmouth. Copper ore has been produced from the peat ashes of a turf pit near Dolgelly. Slates are quarried in the Berwyn mountains; and there are quarries producing slates of excellent quality at Festiniog near the Caernarvonshire border. The slates are shipped in the estuary of the Traeth Bychan, near the place where they are raised.

It was the opinion of some former observers that Cader Idris and some other mountains presented traces of volcanic agency. 'The steeper part' of this mountain, says Mr. Pen-

nant, 'to the highest peak, or Pen-y-Gadair, grows more and more rocky; the approach to the summit extremely so, and covered with huge fragments of discoloured rocks, very rugged, and cemented by a semi-vitrified matter, which gives them a very volcanic look, added to their disjointed adventitious appearance. I met with, on my ascent, quantities of pumice of the same cellular kind with the toadstone of Derbyshire, but of a green colour. The day proved so wet and misty that I lost the enjoyment of the great view from the summit. I could only see that the spot I was on was a rude aggregate of strangely disordered masses. I could at intervals perceive a stupendous precipice on one side where the hill recedes inwards, forming a sort of theatre, with a lake at the bottom; yet very high in comparison of the base of the mountain. On the other side, at a nearer distance, I saw Craig Cay, a great rock, with a lake beneath, lodged in a deep hollow, possibly the crater of an antient volcano.'

Hydrography and Communications.—The principal rivers belonging to the county are the Dee, the Maw, and the Dovey, with their respective affluents.

The Dee rises in the valley skirted by the Berwyn mountains, very near the road leading from Bala to Dolgelley; from its source it flows north-east four miles (receiving by the way the Lew and the Twrch, each considerably longer than itself) into the lake of Bala, called Llyn Tegid, *i.e.* 'the fair lake,' by the Welsh, but by the English, Pimble Meer. [BALA.] From the lower end of the lake the Dee flows 12 miles in a winding course north-east to Corwen, receiving a number of mountain streams: from Corwen it flows five miles east to the border of the county, which it divides from Denbighshire for two or three miles farther, before finally quitting it. The Trewern, or Glettwr, a feeder of the Dee, rises in the northern part of the county, and has a south-east course of about fourteen miles into the Dee, which it joins just below the lake of Bala. Just above Corwen the Dee receives the Alwen, one of its tributaries, which though belonging chiefly to Denbighshire, has five miles of its course upon and three miles within the border of this county.

The Maw, otherwise called Mawddach, rises near the centre of the county, and has a southern course of eight miles to its junction with the Llynauddon, which lies more to the westward, and is of about equal length. From the junction of the Llynauddon the Mawddach flows south-south-west, four miles to the junction of the Wnion (twelve miles long), which rises close to the source of the Dee, and flows along the same valley, but in an opposite direction. For the remainder of its course, which is about eight miles south-west, the Maw is a tide river. In this part of its course it expands into an æstuary in some places a mile wide, and in great part dry at low water.

The Dovey, or Dyfi, rises just within the border of the county, east of the mountain Arran Fowddy, in the Berwyn chain. From its source it flows south-west nearly thirty miles through a winding vale into the bay of Cardigan. It receives a number of small mountain streams, of which the Tafalog, the Afon, the Dulas, and the Cwmcelli are the principal. A part of the course of the Dovey itself and of the Tafalog, and the whole course of the Afon and the Dulas, belong to Montgomeryshire. The lower part of the course of the Dovey is on the border of Merionethshire, which it separates first from Montgomeryshire, and then from Cardiganshire. Near the mouth it expands into a wide æstuary, the greater part of which is dry at low water. The Dovey is not mentioned in Priestley's 'History of Navigable Rivers' as navigable, but is marked in the map which accompanies that work as navigable up to Machynlleth, or Machynleth, at the junction of the Cwmcelli and the Dulas, twelve or thirteen miles from the mouth of the river.

The Disynwy rises in the Berwyn mountains, a little to the north-east of Cader Idris, and flows south-west sixteen miles into the sea between the Maw and the Dovey. About three miles from its source it expands into a small lake, called Llyn-y-Myngil, which in width nearly fills the valley of Tal-y-Llyn, leaving only a narrow road on one side, and extends in length about a mile. The Disynwy above its mouth expands into an æstuary of about a mile wide, but just at the mouth is contracted into a very narrow channel.

None of these streams, except the Dovey, are navigable: the æstuary at the mouth of the Mowddy forms the harbour of Barmouth.

There are many lakes, most of them small. The largest

are Llyn-Tegid, or Bala Lake, and Llyn-y-Myngil, already noticed.

The principal roads are those from London by Shrewsbury to Corwen and Bangor, to Bala and Caernarvon, and to Dolgelley, or Dolgellu, and Barmouth, with branches to Towyn. The first of these enters the county on the east from Denbighshire, a little beyond Llangollen, and runs along the valley of the Dee to Corwen, from which place it follows the valley of the Alwen into Denbighshire. There are two Bala roads, both branching off from this to the left, one at Corwen, which follows the right bank of the Dee up the valley to Bala, the other a little beyond Corwen, which follows a valley parallel to that of the Dee, from which it is separated by intervening hills. The Caernarvon road runs up the valley of the Trewern by Festiniog and Tan-y-Bwlch to Beddgelert, with a branch from Tan-y-Bwlch by the coast to Harlech and Barmouth. Another road from Bala follows the valley of the Dee and the Wnion to Dolgelley and Barmouth. There is a nearer road from London to Bala by Shrewsbury and Llangynnog.

The Dolgelley and Barmouth road runs from Shrewsbury, through Welshpool and Llanfair (Montgomeryshire), enters the county by the valley of the Tafalog, and follows that valley and the vale of the Dovey to Dinas-y-Mowddy, or Mowddw, from which place it runs west to Dolgelley and Barmouth. Two branches from this road run to Towyn; one a little before reaching Dinas-y-Mowddy, which follows the vale of the Dovey and then the coast; the other a little before reaching Dolgelley, which follows the vale of the Disynwy. This first branch to Towyn is partly in Montgomery and Cardigan shires, and communicates with Machynlleth and Aberystwith.

Divisions, Towns, &c.—This county, called by the Welsh Meirionydd, or Meirionydd, is the only one in Wales that, with the addition merely of the word 'shire,' retains its antient designation. This name is supposed by some to be derived from Meirion, grandson of a chieftain to whom a large territory in this part of Wales was assigned in the fifth century. If however the district was known to the Romans, as some think, by the name Mervinia, which evidently contains the same root (Mervin, or Meruin) as Meirion-ydd, the name must be of earlier origin.

Writers are not agreed as to the antient division of the county; but its limits appear to have undergone considerable change. One cantref, that of Arwddwy, or Arddwy, south of the river Dovey or Dyfi, was by Henry VIII. added to Montgomeryshire, and the cwmwts or comots of Edermon and Glyndyfrdwy were detached from Powys-land, and added to this county.

The present divisions, with their relative situation and their population in 1831, are as follows:—

Ardwdwy, or Arddwy,	N.W.	10,499
Edermon, or Edeyrnion,	E.	4,905
Estimaner, or Estumaner,	S.	4,631
Penllyn	N. & N.E.	6,654
Talybont, or Tal-y-bont, and Mowddy,	S. & S.E.	8,547
		35,236
Militia		79
		35,315

There are five antient market-towns, namely: Bala and Dolgelley, the assize-towns; Harlech, the place of county elections; Corwen and Dinas-y-Mowddy; and two, where markets have been established of late years, viz. Towyn and Barmouth. [BARMOUTH.]

Bala is in the parish of Llanykil or Llanyeil, in the hundred of Penllyn, near the outlet by which the Dee quits the lake of Bala; 194 miles from London by Shrewsbury and Llangynnog, or 207 miles by Shrewsbury and Corwen. [BALA.]

The population of Llanykil parish was, in 1831, 2359: there was no separate return of the population of the town, but in 1821 it contained 1163 inhabitants out of 2467, the whole population of the parish at that time.

The living of Llanykil is a rectory, in the archdeaconry and diocese of St. Asaph: of the clear annual value of 2507, with a glebe-house, in the gift of the bishop of St. Asaph.

There were in the whole parish, in 1833, two day-schools with 130 children; one of these, a grammar-school, with

75 boys, was partly supported by an endowment. There were seven Sunday-schools, with 1088 scholars.

Dolgelley, Dolgelleu, Dolgellau, or Dostellen (from *dol*, dale, and *gelli, gellen*, or *celli*, a grove of *hulzeis*), is in the hundred of Talybont and Mowddy, on the south bank of the Wnion, a mile or two above its junction with the Maw, 208 miles from London by Shrewsbury, Welshpool, Llanfair, and Dinas-y-Mowddy. This town came into possession of Owain Glyndwr during his rebellion, and from here (A.D. 1400) he despatched ambassadors to France. It was the scene of a smart skirmish during the civil wars of Charles I., in which the parliamentarians were victorious. The town is in a delightful valley: the streets are narrow and irregularly laid out; and the houses are for the most part small, and ill built of limestone without mortar. Within the last few years however some handsome dwellings have been erected, and the general appearance of the town materially improved. The church is a neat structure, capable of accommodating a thousand persons, but destitute of any architectural pretensions. The county hall and county gaol were both erected in the present century; the former is a neat stone building, near the river Wnion. The town-hall is scarcely distinguishable from the ordinary houses, and the market-house is a low square edifice. There is a neat stone bridge of seven arches over the river Wnion.

The population of the parish (which is very extensive) was, in 1831, 4087; less than a fourth of which was agricultural. Dolgelley is the most populous and most commercial town in the county. The Population Returns give 72 males above twenty years of age as employed in the manufacture of 'webs,' or coarse woollen cloths and flannels. They are made in the houses and cottages of the weavers. Fulling-mills and bleaching-grounds have been established in the neighbourhood of the town; and the cloths, when finished, are bought up by agents, and sent to Liverpool for exportation to America, or to Shrewsbury, from whence they are sent to different parts of England. There is a good deal of business done in tanning and dressing lambskins and kid-skins, which are sent to Worcester and other places. The markets are on Tuesday and Saturday, and there are several yearly fairs. The summer assizes and the Easter and Michaelmas quarter-sessions are held at Dolgelley; also the petty-sessions for the division, and, commonly, the county court for the recovery of small debts.

The living is a rectory, in the archdeaconry of Merioneth and diocese of Bangor, of the clear yearly value of 440*l*. There are several dissenting places of worship in the town or parish, chiefly belonging to the Independents or the Calvinistic Methodists. There were, in 1833, five day-schools with 155 children: of these schools, one with 33 children was partly supported by an endowment; one day and Sunday national-school, with about 100 children, and some adults on Sunday; and fourteen Sunday-schools, with nearly 1400 scholars.

Harlech is in the parish of Llandandwg, in the hundred of Ardudwy, near the shore of Cardigan bay, 232½ miles from London by Dolgelley and Barmouth. It has been supposed that Harlech was a Roman post, but for this opinion there is no just ground. An antient British fortress, called originally Twr Bronwen, and, at an after-period, Caer Collwyn, occupied the site of the present castle erected by Edward I. This strong fortress was held in the civil war of the Roses by Dafydd ap Ievon ap Einion, a stout partisan of the house of Lancaster. Dafydd, after a valiant defence, was obliged to surrender to Sir Richard Herbert, on an engagement that his life should be spared. Edward IV. would have put him to death in violation of this engagement, had not Sir Richard declared that if the king persisted in his purpose, he would replace Dafydd in the castle, and the king might send whom he would to take him out. In the civil war of Charles I. the castle changed masters once or twice, but was finally taken by the parliamentarians under General Mytton, March, 1647. The town of Harlech is little more than a village of small size and insignificant appearance, situated between a wild and desolate mountain country and the sea. The most striking object is the castle, the ruins of which are situated on a lofty rock facing the bay, and rising above an extensive marsh once occupied by the sea. Its walls are tolerably perfect; they form a square of about seventy yards each way, with a round tower at each corner. From these corner towers formerly rose elegant turrets, but these are in great part

destroyed. There are round towers on each side of the entrance. The apartments, now open to the sky, are of large dimensions. There are traces of the antient British fortress in the foundations of the present structure. Toward the sea, the castle was protected by the inaccessible precipice on which it stood; on the land side it was strengthened by a deep ditch cut with enormous labour in the solid rock. The assizes and county court, once held at Harlech, have been long removed; the market, held on Saturday, has fallen almost or quite into disuse; and the county election and the poll for the district are the only public business transacted here. There are several fairs, chiefly for live stock. The population of the parish, in 1831, was 658, about one-third agricultural.

The living of Llandandwg is a rectory, united with the chapelry of Llanbedr, in the archdeaconry of Merioneth and diocese of Bangor, of the clear yearly value of 194*l*.

There were, in 1835, one boarding-school, with six scholars; one day-school, partly supported by endowment, with 36 scholars; and two Sunday-schools, with 153 scholars.

Corwen is in the hundred of Ederion, on the south bank of the Dee, just below the junction of the Alwen, 194 miles from London on the Holyhead parliamentary road. There was antiently a British or Welsh post near this town, called Caer Drewyn; it consisted of a circular wall a mile and a half round, still remaining, on the summit of a steep hill, and of a circular habitation, now in ruins, within this enclosure. In the invasion of Wales by Henry II., A.D. 1165, the progress of that monarch was stopped by the assembling of the Welsh forces at Corwen under Owain Gwynedd. There are said to be some traces of the Welsh encampment near the town. Corwen is a small place, but neat; it stands on a rising ground just above the river. The church is a neat cruciform building, capable of accommodating about seven hundred persons, in a romantic situation, immediately at the foot of a rocky precipice belonging to the Berwyn mountains. On the south side of the church is a stone shaft or cross, called by the common people 'the sword of Glyndwr;' and on the same side of the churchyard is a neat almshouse for six widows of clergymen. There is another almshouse for eight poor women. One of the county bridewells is at Corwen. 'It is a small house, inhabited by the keeper (who is a shoemaker), his family, and the very few prisoners who are usually to be found here.'

The population of the parish, which is extensive, was, in 1831, 1980, about half agricultural. There are no manufactures. The markets are on Tuesday and Friday, the former for corn; and there are several yearly fairs.

The living is a vicarage, in the archdeaconry and diocese of St. Asaph, of the clear yearly value of 390*l*. There is also a sinecure rectory, of the clear yearly value of 373*l*.

There were, in 1833, one day-school, partly supported by endowment and subscription, with 60 children; one day and boarding-school, with 26 children; and twelve Sunday-schools, with 748 scholars. There are several dissenting congregations in the parish, chiefly Calvinistic Methodists.

Dinas-y-Mowddy, or Dinasmouthy, is in the parish of Mallwydd, and in the hundred of Tal-y-bont and Mowddy, 203 miles from London through Ludlow, Montgomery, Welshpool, and Llanfair. It has been thought by some to have been formerly a place of greater importance, but no marks of former greatness can be traced: it was perhaps the residence of some small chieftain. The town is situated on a shelf of rock at the junction of the Cerris, a small stream, with the Dovey: it consists of a few mean cottages, one story high, built of mud, and thatched with rushes. The population of the parish of Mallwydd in 1831 was 1137; but the part which is in the county of Merioneth, in which the town stands, was 998: the town itself perhaps contains 300 inhabitants. A good deal of flannel is made in the neighbourhood, partly in the weavers' cottages, and partly in factories. There is a corporation at Dinas-y-Mowddy: the mayor exercises a conjoint jurisdiction with the county magistrates in the lordship or borough, which comprehends the parish of Mallwydd and the greater part of that of Llan-y-Mowddy. There are stocks, and a crib or little prison, which are scarcely used; and the municipal institutions altogether are characterised as 'trifling and harmless.' (*Munic. Commiss. Report.*)

The living of Mallwydd is a rectory, of the clear yearly value of 255*l*, with a glebe-house, in the archdeaconry and

diocese of St. Asaph. The church is a large building, capable of accommodating a thousand people, but very thinly attended, most of the parishioners being dissenters. There were in the parish in 1833 one day-school, with 30 children, and nine Sunday-schools, with 539 scholars.

Towyn, or Tywyn, is in the hundred of Estimaner, near the coast, between the æstuaries of the Disynwy and Dovey, but much nearer to the former, 227 miles from London by Dinas-y-Mowddy and Machynlleth. The town consists of some good-looking houses, built chiefly of a coarse grey stone quarried in the neighbourhood. It is frequented in the bathing season by visitors attracted by the pleasantness of the situation in a quiet vale commanding a view of the sea and backed by lofty mountains. The church is a spacious building of considerable antiquity: it contains some venerable monuments; and in the churchyard are two rude pillars, one of them seven feet high, adorned with a cross, and bearing an inscription in antient but illegible characters. In a field near the church is a spring, called St. Cadvan's Well, the waters of which are considered beneficial in scrofulous, rheumatic, and cutaneous disorders. The spring is now enclosed, and two baths have been formed, with dressing-rooms attached.

The population of the parish in 1831 was 2694, about half agricultural. Some webs and flannels are manufactured. Races are held near the town, and are well attended. A customary market is held on Friday, and there is a yearly fair. The village and port of Aberdovey is in the parish: it is frequented as a bathing-place, having the recommendation of a firm hard sand: it is on the æstuary of the Dovey. There are dissenting chapels here. Slate-quarries are worked near Aberdovey, and a considerable share of the coasting trade is carried on at the port, which is a member of Aberystwith.

The living of Towyn is a vicarage, in the archdeaconry of Merioneth and the diocese of Bangor, of the clear yearly value of 224*l.*, with a glebe-house.

There were, in 1833, four day-schools (one of them partly supported by endowment), each with about 50 scholars; two boarding-schools, each with about 10 scholars; and eleven Sunday-schools, with 50 to 80 scholars each, chiefly connected with dissenters.

Divisions for Ecclesiastical and Legal purposes.—The county of Merioneth is partly in the diocese of St. Asaph and partly in that of Bangor, both in the ecclesiastical province of Canterbury. It is divided into five rural deaneries, which have the same name with the hundreds, and are nearly or quite conterminous with them. The deaneries of Arddwy, Estimaner, and Tal-y-bont are in the archdeaconry of Merioneth and the diocese of Bangor; the deaneries of Mouthwy or Mowddy, Pontlyn or Penllyn, and Idernion or Edeyrnion, are in the archdeaconry and diocese of St. Asaph. The map subjoined to the Third Report of the Church Commissioners represents all that part of the county which is in the diocese of Bangor as forming the single deanery of Arddwy. There are in all thirty-four parishes wholly or chiefly in this county, besides a portion of one parish (Beddgelert), which is chiefly in Caernarvonshire. Four of these parishes are for ecclesiastical purposes, united with others; but there are three sinecure rectories, so that the number of benefices is thirty-three: seventeen of these are in the diocese of Bangor, nine of them in the patronage of the diocesan, and sixteen in that of St. Asaph, of which fourteen are in the bishop's own gift. The benefices are, some of them, tolerably rich; the wealthiest is the rectory of Dolgelly, 440*l.* clear annual value; but most of them are under 200*l.* a year, and eight under 100*l.* a year.

The county is in the North Wales circuit: the Lent assizes and the Epiphany and Midsummer quarter sessions are held at Bala: the Midsummer assizes and the Easter and Michaelmas quarter-sessions, at Dolgelly. The county gaol is at Dolgelly; it is well situated, but badly arranged and deficient in many requisites. The number of prisoners is happily small. The committals to the county gaol, on the average of the years 1829 to 1835, were only about 28 annually. There are bridewells or houses of correction at Corwen, described above, and at Bala. The latter is a small building, part of the guildhall, insecure, out of repair, and slovenly. When visited by the inspectors of prisons (in 1836) there were no prisoners.

The court of election for the county, which returns one member to parliament, is held at Harlech: the polling—
P. C., No. 926.

stations are Harlech, Bala, Dolgelly, Corwen, and Towyn. There are no parliamentary boroughs in the county.

History, Antiquities, &c.—In the earliest period of the authentic history of the island, Merionethshire was included in the territory of the Ordovices, who occupied nearly the whole of North Wales, a considerable part of Shropshire, and a part of Cheshire. [BRITANNIA.] In the Roman division of the island, it was included in the province of Britannia Secunda. It is said to have been called Mervinia by the Romans.

There are several traces of Roman works in this county. There are remains of camps near Bala [BALA]; and in the immediate neighbourhood of that town is Tommen-y-Bala, an artificial mound supposed to be a Roman work, and to have had a small fort on its summit.

Tommen-y-Mûr, 'the mount within the wall,' a station, of which the ditch and bank, with vestiges of a wall, remain, near Ffestiniog, is supposed to be the Heriri Mons of Richard of Cirencester, though Stukeley places it near Bala. Castell Prysor, a hilly fort about three miles east of Trawsfynydd, is considered by Pennant to have been originally Roman. The Dovey river is considered to be the Stucia (*Στροκία*) of Ptolemy. A Roman road from Maridunum, or Muridunum (Caernarthen) to Segontium (Caer Seiont, near Caernarvon) led through the county. It may be traced in the neighbourhood of Trawsfynydd through Tommen-y-Mûr, where it is called Sarn-Helen, a name which is interpreted by some 'the road or causeway of Helen,' the wife of the usurper Maximus, who assumed the purple (A.D. 381) in the time of the emperors Gratian and Theodosius; and by others, 'the road of the legion.' From this road, at or near Tommen-y-Mûr, roads are supposed to have led in one direction to Conovium (Caer Rhun, near Aber-Conway), and in another direction to Bala.

The Sarn-Helen is now entirely covered with turf, and is to be distinguished only by its elevation above the rest of the surface; but on digging, the layers of stone of which it was made are discoverable throughout the whole of its visible course: the aggregate breadth of these layers is about twenty-four feet. There are several tumuli or barrows near the road. There is a group of other monuments, probably sepulchral, near Rhyd-ar-Helen, a quarter of a mile from the Sarn-Helen, of considerable but undetermined antiquity. In the neighbourhood of Rhyd Goch, not far from Trawsfynydd, is a grave, called the Grave of Porus, covered with an inscribed stone, evidently Roman; and near it is a great upright monumental stone, of a kind frequent in Wales and in northern Europe. Roman coins, sepulchral urns, and other antiquities have been dug up in various places, particularly near Castell Prysor and Tommen-y-Mûr; at Caer Gai, near the south-west end of Llyn Tegid, or Bala Lake (probably the site of a Roman fort); and at Cefyn Caer, near Pennal, where was the site of another Roman fort.

There are a stone enclosure of fort and several other British antiquities near Llanddewi, between Barmouth and Harlech; and in the same neighbourhood earnedds, cromlechs, and other Druidical remains. Other Druidical remains are found near Rhyd-ar-Helen, not far from Ffestiniog. They are called Beddau Gwyr Arddwy, 'the graves of the men of Arddwy.'

During the Saxon period and the reigns of the earlier English kings of the Norman dynasty, Merionethshire does not appear to have been the scene of events of historical interest. One battle took place between the Saxons and the Britons under the royal bard Llywarch Hên, between Corwen and Bala: the Briton lost the last of his sons in this battle, a bereavement which he has commemorated in one of his elegies. Merionethshire was afterwards the scene probably of many of those bloody feuds which disfigure the annals of Wales; but the remote and secluded situation of the county secured it from any serious foreign invasion. In proportion however as the consolidation of the Anglo-Norman power enabled the English to press the Welsh more closely, these previously unassailed fastnesses became the scene of contest. The invasion of Henry II., his advance to Corwen, and the stop put to his progress there by the Welsh under Owain Gwynedd (A.D. 1165), have been noticed. Henry retreated into England after sustaining a great loss in men and stores.

This county was probably conquered by Edward I., a little before the final conquest of Wales; as Harlech Castle was completed before 1283, in which year Hugh de Wloneslow was constable of it, Merionethshire was the scene of the

rebellion of Owain Glyndwr. [GLENDWR, OWEN.] Harlech Castle was one of his conquests.

In the war of the Roses, Harlech was held for the Lancasterians, but taken, as mentioned above, by Sir Richard Herbert. After the war was concluded, the county became and long continued to be the scene of great confusion. A multitude of outlaws and felons established themselves in the neighbourhood of Dinas-y-Mowddy, and perpetrated a variety of crimes, burning, robbing, and murdering in large bands, and driving cattle in open day with the greatest impunity. To quell these outrages, a commission was granted by Queen Mary to two gentlemen of the county; one of them Lewis Owen, vico-chamberlain and baron of the exchequer of North Wales. In pursuance of this commission, eighty of the band were seized and punished. To revenge this severity, Mr. Owen was waylaid and murdered when returning from the Montgomeryshire assizes (A.D. 1555), at a place now called, from the deed, Llydiart-y-Barwn, 'the baron's gate.' The vigorous measures to which this outrage gave rise led to the extirpation of the banditti, some of whom were executed, and the rest fled. The traditions of the country attest the terror which these ruffians excited. Travellers forsook the common road to Shrewsbury to avoid their haunts. In the civil war of Charles I., Harlech Castle was the object of contention. The repeated captures of this place, and a skirmish near Dolgelley, which had been garrisoned for the parliament, were the only incidents of the contest which occurred within the county.

The principal remains of the middle ages are Harlech Castle, already described, and the ruins of Cymmer Abbey, near Dolgelley, with two or three smaller castellated build-

ings. Cymmer Abbey appears to have been founded about A.D. 1198, by two Welsh chieftains, for Cistercian monks the yearly revenue at the dissolution was 58*l.* 15*s.* 4*d.* gross, or 51*l.* 13*s.* 4*d.* clear. Part of the church is still to be seen in a rich flat near the Maw, and shows the antient greatness of the structure. The east end has three narrow pointed windows, and three smaller ones over them: it is mantled with thick ivy. The great hall and the abbot's lodgings were used as a farm-house in Mr. Pennant's time.

Llys Bradwen, between Dolgelley and Towyn, is the ruin of a rude edifice, the house of an antient Welsh chieftain; and near Llanfihangel-y-Pennant are the remains of a castle supposed to be the castle of Bere, belonging to the last Llewelyn, prince of North Wales, and taken from him by William de Valence, earl of Pembroke, a short time previous to the final conquest of Wales.

Near the road from Bala to Dolgelley is Castell Corn-dochon, the ruin of a fortress of unascertained date.

(Pennant's, Evans's, and Bingley's *Tours in Wales*; *Reauties of England and Wales*; *Parliamentary Papers*; Greenough's *Geological Map of England and Wales*; Walker's do.; Arrowsmith's *Map of England and Wales*, &c.)

STATISTICS.

Population.—Merionethshire is almost entirely an agricultural county. Of 8879 males twenty years of age and upwards, 4959 are engaged in agricultural pursuits, and only 200 in manufacture or in making manufacturing machinery. These 200 are weavers of flannel and other woollens, distributed throughout the villages in small numbers, except that 70 of the men so employed reside at Dolgelley.

The following Table contains a Summary of the Population, &c., of every Hundred, as taken in 1831.

HUNDREDS, CITIES, OR BOROUGHES.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Build- ing.	Unin- habited.	Families chiefly employed in Agri- culture.	Families chiefly employed in trade, manufac- tures, and handicraft.	All other Families not com- prised in the two preced- ing classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.

Militia under training	—	—	—	—	—	—	—	79	—	79	—
Total . . .	6968	7358	53	238	3583	1815	1960	17,194	18,121	35,315	8879

The population of Merionethshire, at each time the census was taken, was, in—

	Males.	Females.	Total.	Increase per cent.
1801	"	"	27,506	"
1811	"	"	30,924	12.42
1821	16,479	17,903	34,382	11.13
1831	17,194	18,121	35,609	3.56

showing an increase between the first and last periods of 8103, or about 29½ per cent. on the whole population, being 17½ per cent. below the whole rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the three following periods of—

	£.	s. d.
1811 were	12,280,	being 7 11 for each inhabitant.
1821 ..	14,559	" 8 5 "
1831 ..	14,865	" 8 4 "

The sum expended for the same purpose for the year ending March, 1838, was 12,228*l.*; and assuming that the population had increased at the same rate of progression since 1831 as in the ten preceding years, the above sum gives an average of 6*s.* 8*d.* for each inhabitant. These averages are below those for the whole of England and Wales.

The sum raised in Merionethshire for poor-rate, county-rate, and other local purposes, in the year ending 25th March,

1833, was 18,405*l.* 11*s.*, and was levied upon the various descriptions of property as follows:—

On land	£17,436	5 <i>s.</i>
Dwelling-houses	793	10
Mills, factories, &c.	99	7
Manorial profits, navigation, &c.	76	9
Total	18,405	11

The amount expended was—
For the relief of the poor . . . £15,247 0*s.*
In suits of law, removal of paupers, &c. . . 379 5
For other purposes . . . 2,442 16

Total 18,069 1

In the returns made up for the subsequent years the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, 1837, and 1838, there were raised 18,039*l.* 14*s.*, 17,188*l.* 4*s.*, 16,458*l.* 17*s.* (not given for 1837), and 15,794*l.* respectively; and the expenditure for each year was as follows:—

	1834.		1835.		1836.		1837.		1838.	
	£.	s.	£.	s.	£.	s.	£.	s.	£.	s.
For the relief of the poor	14,977	4	14,216	7	13,974	4	13,440		12,298	
In suits of law, removal of } paupers, &c.	707	7	841	13	276	4	528		90	
Payments towards the } county-rate	2,322	14	1,528	7	1,077	10	not given.		1,504	
For all other purposes			800	0	893	2	926		823	
Total money expended	£18,007	5	16,976	7	16,111	0	14,904		14,651	

The saving effected on the whole sum expended in 1838, as compared with that expended in 1834, was therefore 3356*l.* 5*s.*, or about 18½ per cent.; and the saving effected on the sum expended for the relief of the poor was rather more than eighteen per cent. in 1838 as compared with the expenditure in 1834.

The number of turnpike trusts in Merionethshire, as ascertained in 1835, under the acts 3rd and 4th Wm. IV., chap. 80, was 6; the number of miles of road under their charge was 261. The annual income arising from tolls and parish compositions in lieu of statute duty was (in 1835) 4288*l.* 14*s.*, and the annual expenditure in the same year was as follows:—

	£.	s.	d.
Manual labour	1,098	12	0
Team labour and carriage of materials	139	10	0
Materials for surface repairs	5	5	0
Tradesmen's bills	117	5	0
Salaries of treasurer, clerk, and surveyor	257	6	0
Law charges	1	16	0
Interest of debt	712	19	0
Improvements	382	16	0
Debts paid off	772	0	0
Incidental expenses	260	13	0
Estimated value of statute duty performed	148	2	0
	3896	4	0

The county expenditure in 1834, exclusive of the relief for the poor, was 1659*l.* 13*s.*, disbursed as follows:—

	£.	s.	d.
Bridges, building and repairs, &c.	724	8	0
Gaols, houses of correction, &c., and maintaining prisoners, &c.	368	18	0
Shire-halls and courts of justice, building, repairing, &c.	30	0	0
Prosecutions	174	6	0
Clerk of the peace	163	10	0
Conveyance of prisoners before trial	33	17	0
Constables, high and special	3	12	0
Coroner	11	12	0
Miscellaneous	149	10	0
Total expenditure	1659	13	0

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 40, 25, and 63; making an average of 5 + annually in the first period, of 3 + in the second period, and of 9 in the third period. The number of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 2, 2, and 9 respectively. All these persons were charged with felonies.

The total number of committals in each of the same years was 2, 3, and 10 respectively; of whom

	1831.	1832.	1833.
The number convicted was	2	2	8
Acquitted	—	—	1
Discharged by proclamation —	—	—	1

At the assizes and sessions, in 1837, 5 persons were charged with crimes in Merionethshire; out of which number none had committed offences against the person, 1 was charged with offence against property committed with violence, and 4 for offences against property committed without violence. The first offender was acquitted, and the remaining 4 were convicted. Of those convicted, 1 was sentenced to be transported for seven years; 1 to be imprisoned two years, or above one year; and 2 for six months or under. Of the offenders, 2 were males and 3 females. Among the whole number, 3 could read and write only imperfectly, and 2 could neither read nor write.

The number of persons qualified to vote for the county members in Merionethshire, as registered in 1837, was 1336. Of these, 711 were freeholders, 103 leaseholders, 504 occupying tenants, 10 trustees, 7 mortgagees, and 1 annuitant: being one in 26 of the whole population, and one in 7 of the male population above twenty years of age, as taken at the census of 1831. The expenses of the last election of county members to parliament were, as usual, paid out of the general county-rate. There was not any contest at the last election for the county.

There is one savings' bank in this county; the number of depositors and amount of deposits on the 20th of November, in each of the following years, were as under:—

	1832.	1833.	1834.	1835.	1836.	1837.
Number of Depositors	629	670	447	435	505	555
Amount of Deposits	£17,098	£16,727	£11,573	£10,683	£12,090	£11,162

The various sums placed in the savings' bank in 1835, 1836, and 1837, were distributed as under:—

	1835.		1836.		1837.	
	Depositors.	Deposits.	Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding £20	251	£2,197	281	£2,493	274	£2,684
" 50	127	3831	163	4,858	130	5,011
" 100	43	2,752	51	3,008	56	5,801
" 150	11	1,304	7	806	10	1,152
" 200	2	341	3	505	4	672
Above	1	263	—	—	1	202
	435	10,689	505	12,090	555	11,162

Education.—The following summary is taken from the Returns on Education laid before parliament in the session of 1835:—

	Schools.	Scholars.	Total.
Daily schools	50		
Number of children at such schools; ages from 4 to 14 years:—			
Males		663	
Females		359	
Sex not specified		878	
			1,900
Sunday-schools	172		
Number of children and others at such schools; ages from 4 to 80 years:—			
Males		3,462	
Females		3,221	
Sex not specified		7,114	
			13,800

Assuming that the population had increased between 1831 and 1833 (the period when the educational inquiry was made) in the same ratio as in the ten preceding years, and that the number of children between the ages of 2 and 15 bore the same proportion to the whole population as it did in 1821, then we find 11,753 as the approximate number of children living in Merionethshire in 1835. If Sunday-schools are returned from places where no other school exists, and the persons who attend them (615 in number) cannot be supposed to attend any other school. At all other places Sunday-school children have opportunity of resorting to other schools also; but in what number or in what proportion duplicate entry of the same children is thus produced, must remain uncertain. Four schools, containing 280 children, which are both daily and Sunday schools, are returned from various places, and duplicate entry is known to have been thus far created. In some of the Sunday-schools there are adults and aged persons as well as children. Making full allowance, even for these two causes, for inaccuracy, it may perhaps be fairly estimated that nearly all the children are receiving instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscriptions and payments from scholars.	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.
Daily Schools	17	445	3	249	26	1000	4	203
Sunday Schools	1	65	169	13,620	—	—	2	115
Total	18	510	172	13,869	26	1000	6	321

The schools established by Dissenters, included in the above statements, are—

	Scholars.
Daily schools	8, containing 246
Sunday-schools	161 13,143

The schools established since 1818 are—

	Scholars.
Daily schools	23, containing 999
Sunday-schools	158 12,190

Four boarding-schools are included in the number of daily schools given above. No school in this county appears to be confined to members of the Established Church, or of any other religious denomination, such exclusion being

disclaimed in almost every instance, especially in schools established by Dissenters, with whom it is here included Wesleyan Methodists.

MERLIN, the English name for the *Falco Esalon* of Linnaeus; *Emerillon*, *Rochier*, and *Faucon de Roche* of the French; *Stein Falke* of the Germans; *Smerlio*, *Smeriglio*, and *Fulchetto* of the Italians; and *Coruwalch* and *Llymysten* of the antient British.

Description.—*Old Male*.—Bill bluish-horn colour, palest at the base, darkest towards the tip; cere yellow, irides dark brown; top of the head blue-gray, with dark lines passing backward; the cheeks and thence round the back of the neck pale reddish brown, also marked with dark streaks, forming a collar; the whole of the back and wing-coverts fine blue-gray, the shaft of each feather forming a dark central line; wing primaries pitch black; upper surface of the tail-feathers bluish-gray over two-thirds of their length, with slight indications of three dark bands, the distal third nearly uniform black, the tips of all the feathers white; breast, belly, thighs, and under tail-coverts rufous, with brown central patches, and darker brown streaks; under surface of the tail-feathers barred with two shades of gray, a broad, dark, terminal band, and white tips; legs and toes yellow, claws black.

Female.—Top of the head, back, wing-coverts, and secondaries dark liver brown, the shaft of each feather darker, the edge tipped with red; the tail-feathers brown, with fine narrow transverse bars of wood-brown; under surface of the body pale brownish white, with darker brown longitudinal patches; bill, cere, eyes, legs, toes and claws, as in the male.

Young Males.—Resembling the females.

Birds of the Year.—The wings do not reach so far towards the end of the tail as those in the adult. (Yarrell, *Hist. of British Birds*.)

The length of this, the smallest of the British hawks, is from ten to twelve inches, according to sex.

Habits, Reproduction, &c.—‘Assuredly,’ saith the author of the Book of Falconrie, ‘divers of these Merlyns become passing good hawkes and verie skilful; their property by nature is to kill thrushes, larks, and partridges. They flee with greater fierceness and more hotely than any other hawke of prey. They are of greater pleasure, and full of courage, and men must make greater care, and take good heed to them, for they are such busie and unruey things with their beakes, as divers times they eate off their own feet and talions very unnaturally, so as they die of it. And this is the reason and true cause, that seldom or never shall you see a mewed or entermewed Merlyn. For that in the Mew they do spoyle themselves, as I have before declared.’ Sir John Sebright says that the Merlin will take blackbirds and thrushes, and that he may be made to *wait on*, that is, hover near till the bird be pursued and started again; ‘and though a Merlin will kill a partridge, they are not strong enough to be effective in the field.’ (*Observations on Hawking*.) The nest is placed on the ground, and but poorly made. The eggs (one inch seven lines long, and one inch three lines broad), vary in number from four to five, and are mottled with reddish-brown of two shades of colour.

Geographical Distribution.—Europe, as high as Denmark, and as low as the shores of the Mediterranean; Smyrna (Strickland), Cape of Good Hope (Smith), *quæretamen*; North America, according to Dr. Richardson, who says that ‘a single pair were seen in the neighbourhood of Carlton House in May, 1827, and the female was shot. In the oviduct there were several full-sized white eggs, clouded at one end with a few bronze-coloured spots. Another specimen, probably also a female, was killed at Sault St. Marie, between Lakes Huron and Superior, but it could not be preserved.’ Dr. Richardson was unable to ascertain the extent of its migrations on the American continent; neither Wilson, Nuttall, nor the Prince of Musignano notices it as occurring in the United States; but the latter (*Specchio Comparativo*) mentions it as very rare at Rome, and he only observed the young, and that in winter. It ‘was formerly considered to be only a winter visitor to this country; but it is now very well ascertained that this species breeds on the moors of some northern countries. Mr. Selby has found the nest several times in Northumberland; and Dr. Heysham mentions three instances that came to his knowledge of Merlins’ nests in Cumberland, where, he says, this bird remains all the year. Mr. Eyton tells me that it breeds on Cader Idris; and Mr. Dovaston sent a notice to his friend

Mr. Bewick, “on the authority of the gamekeeper at Wynstay Park, North Wales, that he had often seen the nest of the Merlin, and that it built and bred there in the summer of 1826.”

‘In the more southern counties of Cornwall and Devonshire the Merlin is considered to be rare, and only seen in winter. On our eastern coast it is killed, but not very often, in Kent, Essex, and Norfolk. The specimens obtained are generally young birds, and these occur most frequently in autumn, or at the beginning of winter. In Ireland, according to Mr. Thompson, the Merlin is indigenous in several northern counties. It breeds also in Scotland, in Orkney, and in Shetland. In North Wales the young birds are called Stone Falcons; but among ornithologists the Stone Falcon is considered to be an adult bird. It is not however improbable that the habit of sitting on a bare stone or portion of rock, by which this species has acquired the name of Stone Falcon, is common to it at all ages and in other countries.’ (Yarrell, *loc. cit.*)

The character of the Merlin is thus summed up in the old French quatrain:—

‘L’Emerillon beau par extrémité
A le cœur gay, et fort hardy courage,
Et bien qu’il soit petit, si fait-il rage
A pour suyvir sa proye en gayeté.’

The Merlin.

Upper figure, young male of the year, which the female, unless very old resembles; lower figure, adult male.

MERLIN, or, more properly, **MERDWIN**. Some of the Welsh antiquaries speak of three Merlins: Merdwin Emrys, or Merlinus Ambrosius; Merdwin Wylt, or Merlinus Caledonius; or Merlinus Sylvestris; and Merdwin ap Morvryn, otherwise called Merlinus Avalonius (from a poem ascribed to him, entitled ‘Avalleuau,’ or the Orchard), and also known by the Latin names of Melchinus, Melkinus, and Mervynus. (Nicholson’s *Eng. Hist. Library*.) It is generally agreed however that the second and third are the same person; and it is far from improbable that all the three Merlins are but one individual. Of Merlin Ambrosius the principal account we have is in Geoffrey of Monmouth’s ‘*Historia Brittonum*,’ where he is represented as a great prophet and enchanter, who flourished in the time of King Vortigern, or about the middle of the fifth century. This is the Merlin who is celebrated by many of our old poets, especially by Spenser, in the ‘*Faery Queen*,’ book iii., and elsewhere; and he is also the subject of the English metrical romance of Merlin, of the first part of which there is a copy in the library of Lincoln’s Inn, and a more antient one, containing also a second part, in the Auchinleck MS. in the Advocates’ Library, and of which Mr. Ellis has given an analysis, with extracts, in the first volume of his ‘*Specimens of Early English Metrical Romances*.’

Of the Caledonian Merlin there is a life in Latin hexameters, extending to 1528 lines, by Geoffrey of Monmouth, who professes to have compiled it from an Armorican original; it is extant in one of the Cotton MSS. (Vesp., E. iv.), and has never been printed, but there is an account of it in the same volume of Mr. Ellis's work. (See also Pinkerton's *Inquiry into the Early History of Scotland*, ii. 275.) Fordun, in the third book of his 'Scotichronicon,' has a long account of Merlin the Wild, and especially of an interview between him and St. Kentigern, bishop of Glasgow, who lived in the latter part of the sixth century. This account agrees with other testimonies as to the age of the Caledonian Merlin, and also as to his having been a native and inhabitant, not of the country now called Wales, but of the Welsh kingdom of Reged, or Strathclyd, which extended over the south-west of Scotland. That district, it may be added, still retains several traditionary recollections of the fame of Merlin; his grave, in particular, is yet shown near the village of Drumelzier, on the Tweed. (See Sir W. Scott's *Introduct. to Romance of Sir Tristram*, p. 38; and Note to *Vision of Don Roderick*, p. 367, edits. of 1834.) Collections of the Prophecies of Merlin have appeared in French, at Paris, 1498; in English, at London, 1529 and 1533; in Latin, at Venice, 1554; and there are also manuscripts of them, in French and English, in the Cotton and other libraries. (See Warton, *Hist. of Eng. Poet.*, iii. 430, edit. of 1824.) We find some of them applied by the poet Laurence Minot, who wrote about 1360, to the victories of Edward III. (*Ibid.*, and Minot's *Poems*, by Ritson, note, pp. 100-104.) It appears to have been generally assumed by the French and English collectors that the author of these prophecies was Merlinus Ambrosius; but in the Scottish edition, printed at Edinburgh, 1615, they are attributed to Merlin the Wild, or the Caledonian. They appear to have been very famous in Scotland in the early part of the sixteenth century. (See Sir W. Scott's *Minstrelsy of the Border*, iv., pp. 134-147.) The 'Avallenau,' and some other Welsh poems, attributed to Merdhin Wyllt, are published in the 'Welsh Archæology,' 3 vols. 8vo., 1801, &c. (See Mr. Sharon Turner's vindication of the authenticity of these productions, printed at the end of his *History of the Anglo-Saxons*, vol. iii., 1823.)

MERLON. [EPAULEMENT.]

MERLU'CIUS, a genus of fishes, belonging to the *Gadidae*, or family of Codfishes, distinguished by the possession of only two dorsal fins and one anal fin, and the absence of barbules on the chin. This latter character distinguishes the species of the genus *Merlucius* from the Burbot (*Lota*) and Rocklings (*Motella*), and there being only two dorsal fins removes the present genus from the more typical Codfishes, where there are three dorsal fins.

The hake (*Merlucius vulgaris*, Cuv.) affords a familiar example of this genus. This fish is found on various parts of the coasts both of England and Ireland. It inhabits also the seas of the western coast of Norway, and is common on the northern shore of the Mediterranean. 'A hake of three feet eight inches long,' says Mr. Yarrell, in his 'History of British Fishes,' 'supplied the means of obtaining the following particulars. The length of the head, compared to the length of the body alone, as one to three, the depth of the body not so great as the length of the head; the ventral fins are placed in advance of the pectorals, the rays not unequally elongated; the pectoral fins commence in a line under the posterior angle of the operculum, the rays ending with the end of the first dorsal fin: the first dorsal fin itself short and triangular in shape; the second dorsal fin commences in a line over the vent; the anal fin begins immediately behind the vent; both the second dorsal fin and the anal fin terminate on the same plane, near the tail; the rays strong and stiff: the caudal rays about three inches long, and nearly even.

'The fin rays in number are:—Dorsal 10, 29; pectoral 11; ventral 7; anal 21; caudal 19.

'The head is depressed; the inside of the mouth and gill-covers black; the lower jaw the longest; teeth slender and sharp, in a single row in each jaw; the irides yellow, with a dark outer circle; the lateral line of the body straight throughout the posterior half, then gradually rising to the upper edge of the operculum; the appearance of the lateral line is that of one white line between two dark ones; the scales large; colour of the body dusky brown above, lighter beneath; dorsal and caudal fins dark; ventral and anal fins pale brown.'

The *Gadus Maxillicornis* of Forster and the *G. Maraldi* of Risso are mentioned by Cuvier as species belonging to the present genus.

ME'ROE (Pezæology), Schumacher's name for certain cowry-shells, *Cytherææ sulcata, scripta, hians*, &c.

ME'ROE. [NILE.]

MERO'PIDÆ, a family of Fissirostral birds which, in the opinion of Mr. Vigors, is most nearly connected with the conterminous tribe of *Tenuirostres* by the length, slenderness, and downward curvature of the bill. He adds that it exhibits at first sight a decided discrepancy with the succeeding family of *Hirundinidæ*, where the bill is short and wide; and that if we examine only the typical species of each, we must admit that in respect to these particulars there is a manifest distinction between them. Independently however of the general characters in which both families approach each other, such as the breadth of the *ristus* of the bill, the short and feeble legs, the strength of the wing, and the consequent habit of using that member chiefly in seeking their support, a gradual approximation is found to take place even in their bills; those of some of the extreme species of *Merops* becoming shorter as they approach *Hirundo*; while those of some of the latter group partially desert their own type, and by degrees assume the lengthened form of the bill of the *Bee-eaters*. The tail of *Merops* again is equally found to desert the typical characters of the group, namely, the greater length of the two middle feathers, in order to become even in some species, then slightly forked, and at length to be identified with the fully forked tail of *Hirundo*. Mr. Vigors is further of opinion that among the *Tenuirostres* the genus *Promerops* approaches nearest to the fissirostral group by means of *Merops*, the curved bill of which approaches the structure of its own. (Vigors, *On the Natural Affinities that connect the Orders and Families of Birds*. Linn. Trans., vol. xv.)

Mr. Swainson (*Classification of Birds*, vol. ii.) is of opinion that the *Meropidæ*, or Bee-eaters, succeed the Swallows, and says of the *Merops Apiaster* [BEE-EATER], that it annually visits Italy in flocks of twenty or thirty, and may be seen skimming over the vineyards and olive plantations with a flight much resembling the swallow, though more direct and less rapid. He observes that their bill is indeed considerably longer and more slender, but remarks that this difference is softened down by the intervention of the genus *Eurystomus*, containing the *Stallow* *Rollers* of India, Africa, and Australia, which have this organ very short. To these, he thinks, succeed the true Rollers, *Coracias* (Linn.), which arrive in Italy at the same time with the Bee-eaters, and associate also in small flocks. 'These two genera of Rollers,' continues Mr. Swainson, 'are so indissolubly united, that nothing but the strongest prejudice in favour of a preconceived theory could ever have induced certain naturalists (whose labour in other respects have been of much advantage to science) to have placed them in two different orders. The whole structure of the Rollers, their lengthened pointed wings, and their firm and often forked tail, at once induces the idea that they feed upon the wing; while their very short legs, scarcely longer than their hind toe, might have shown their incapacity to alight and walk, like the crows, upon the ground; but this question is at once decided by a knowledge of their economy, which, from personal observation, we have every reason to believe is much like that of the Bee-eaters. The intervention of the Rollers at once lessens the abrupt transition, which would otherwise be apparent, from the perfect-footed Swallows to the zygodactyle Bee-eaters; and we are thus prepared for all those birds whose toes, as it were, are soldered together like those of the *Meropidæ*. Here perhaps we may notice that most beautiful and rare genus *Nyctiorhis*, or Night-feeder, as being in all probability that particular link by which nature connects this family with the Trogons, thereby uniting the three aberrant groups of the *Fissirostres* into one primary circle. M. Temminck, overlooking its particular structure, placed this genus with *Merops*, to which indeed it has a close resemblance; while its connection to *Prionites* (Ill.) in other parts of its organization is no less obvious. Its precise situation in short requires further investigation.' See also KINGFISHER and MELIPHAGIDÆ.

Mr. Swainson gives the following character as distinguishing the family:—

'Wings long, pointed; the first quill as long, or nearly so, as any of the others.'

And he arranges the following genera under it:—

Merops. (Linn.)

Bill very long, slender, slightly curved, compressed; the culmen carinated; the tip entire, sharp, and not bent downward. *Wings* long, pointed; the tips of the lesser quills emarginate. *Tail* lengthened. *Feet* grossorial. (Sw.)

Example, *Merops apiaster*. [BEE-EATER.]

Nyctiornis. (Sw.)

Bill considerably curved, very long; the culmen with a parallel groove on each side. *Wings* rounded, convex. Plumage lax. *Feet* short, insessorial, resembling those of *Prionites*. (Sw.)

Example, *Nyctiornis amictus*.

Description.—Green; crown (in the adult) lilac; front of the throat and breast bright red. (Sw.) Total length about 13 inches, wings $5\frac{1}{2}$, tail (beyond) 3, tarsi hardly half an inch. (Sw.)

Locality, India.

Nyctiornis amictus. (Sw.)

Coracias. (Linn.)

Bill moderate, straight; the sides broad, but much compressed. The tip of the upper mandible bent over that of

Coracias Abyssinica.

the lower, which is obliquely truncate. Nostrils basal, oblique, linear. Gape very wide, extending beneath the eye; the sides bristled. *Feet* insessorial, very short. All the toes cleft to their base; inner toe much the shortest. *Wings* moderate, pointed. (Sw.)

Example, *Coracias Abyssinica*.

Description.—White round the bill; body aquamarino green; back and wing-coverts cinnamon colour; shoulders, rump, and quills blue; tail green, the two middle feathers blue; two long loose processes terminating the two external quills.

Subgenus, *Eurystomus*, Vieill.

Subgeneric Character.—Resembling *Coracias*, but the bill shorter and wider, and the wings longer. *Nostrils* very long. *Rictus* smooth. (Sw.)

Example, *Eurystomus Orientalis*.

Description.—Colour aquamarino green; throat and point of the wing (fouet de l'aile) azure; quills and tail-feathers black; a white stripe upon the wing.

Localities.—Java, the south of New Holland, and all the Polynesian Islands. It is the *Natay-kin* of the natives of the neighbourhood of Sydney, *Dollar-bird* of the colonists, and *Tiong ba tu* of the inhabitants of Sumatra,—*Coracias Orientalis*, Linn.

Eurystomus Orientalis.

Chloropygia. (Sw.)

General form between *Tamatia* and *Coracias*. *Bill* short; the tip not abruptly bent. *Rictus* bristled. *Nostrils* basal, linear, oblique. *Wings* short, convex, reaching only to the rump. The two first quills much graduated; the four next nearly equal and longest. Tail elongated, rounded, and broad. *Feet* as in *Coracias*. Madagascar. (Swainson.)

Example, *Chloropygia Leptosomus*. (Lesson; Ill., Zool., pl. 22.)

Leptosomus. (Vieill.)

Bill about the length of the head, robust. The upper mandible curved and notched near the tip. *Gonys* straight. *Nostrils* oblong, oblique; the margins elevated, naked, and placed towards the middle of the upper mandible. *Feet* short. Toes in pairs, as in *Tamatia*. *Wings* lengthened, pointed; the first and second quills longest. Tail moderate, even. (Sw.)

Example, *Leptosomus viridis*.

Localities.—The country of the Kafirs and the coast of Zanzibar, where it is said to live in the forests on insects and fruits. The form is arranged by Lesson and others under the family *Cuculidae*. [LEPTOSOMUS.]

Mr. Swainson makes the family of *Meropidae* the first of the *Fissirostræ*. It immediately succeeds the *Paradisidae* and precedes the *Halcyonidae* in his arrangement.

M. Lesson, in his 'Table Méthodique,' gives the following genera as constituting the family of the *Meropidae*:—*Merops*, *Alcedo*, *Dacelo*, *Ceyx*, *Syma*, *Todiramphus*, *Momotus*, and *Buceros*. See the articles KINGFISHERS and HORN BILLS.

Leptosomus viridis.

MEROPS. [BEE-EATER: MEROPIDÆ.]

MEROVINGIANS. [FRANCE.]

MERRICK, JAMES, an English divine and poet, born in 1720, died in 1769. At the age of fourteen, while still at Reading school, he published the 'Messiah, a Divine Essay,' and in 1739, at Trinity College, Oxford, he made a translation of the poem of Tryphiodorus on the Capture of Troy. He also published, in 1741, the Greek text of Tryphiodorus. He was chosen Fellow of Trinity College, Oxford, in 1744, and took holy orders, though, owing to infirm health, he never undertook parochial duties. His chief works were, 'A Dissertation on Proverbs, ch. ix.,' 'Prayers for a Time of Earthquakes and Violent Floods,' written in 1756, soon after the earthquake at Lisbon; 'An Encouragement to a Good Life, particularly addressed to some soldiers quartered at Reading.' He appears to have paid great attention to this class of men, who at that time especially required it. He also wrote 'Poems on Sacred Subjects,' and made an excellent translation of the Psalms into English verse. This, beyond all doubt the best poetical translation we have, was unfortunately not adapted for parochial choirs, inasmuch as it was divided into stanzas for music. On this account it has not been used as generally as its merits would justify. He published several other religious treatises, and some remarks on profane as well as sacred writers. Dr. Lowth calls him 'one of the best of men and most eminent of scholars.'

(Doddridge's *Letters*; Chalmers's *Biographical Dictionary*.)

MERSEBURG is one of the three governments into which the Prussian province of Saxony is divided. It is chiefly composed of territories which Saxony was compelled to cede by the treaty of Vienna in 1815, and includes the greater part of the former electoral circle or duchy of Saxony, a small portion of Thuringia, the bishoprics and chapter-lands of Magdeburg, Naumburg, and Zeitz, part of the duchy of Magdeburg, part of the districts of Leipzig and Meissen, with the counties of Mannsfeld and Stolberg, forming an area of 4000 square miles, with a population (1st of January, 1838) of 625,000. The eastern and larger part of the government is flat, with gentle eminences, but no mountains; the western and smaller portion is more mountainous than level, being partly occupied by branches of the Harz mountains and the Thüringerwald: this portion however contains extensive and fertile levels, and the whole of the government, though the soil is unequal, may be called fertile.

MERSEBURG, the chief town of the government, is situated on the river Saale, 15 miles from Leipzig, in 51° 22' N. lat. and 12° E. long. It is an old irregularly built town, with narrow crooked streets, consisting of the town itself, the Close, and the two suburbs Altenburg and Neumarkt, the latter lying on the opposite bank of the Saale, over which there is a large stone bridge. The town is surrounded with walls, and has four gates. The most remarkable buildings are, 1, a fine palace, with a beautiful church, formerly the residence of the bishop, and afterwards of the dukes of

Saxe-Merseburg, of the Albertine line: at present it is used for the government offices; 2, the cathedral, founded in the eleventh century, in which the dukes of Saxe-Merseburg were interred: it has a fine altar-piece by Lucas Cranach, and one of the largest organs in Germany; 3, the cathedral school; 4, the monastery of St. Peter, in the suburb of Altenburg; 5, the palace of Count Zechi; 6, the military hospital; 7, the new town-hall. Several of the schools are likewise handsome buildings. There are manufactories of various kinds, and extensive breweries and distilleries. The trade of the place is considerable, and with the advantages derived from its being the seat of the government, it is a very flourishing town.

(Müller, *Wörterbuch des Preussischen Staates*, 4 vols. 8vo., 1836.)

MERSENNE, MARIN, a very learned philosopher and mathematician, one of the religious order of *Minimes*, was born in 1588 at Oyse, in the present department of Maine, and received his education at the college of *La Flèche*, where he was a fellow-student of Descartes, with whom he formed an intimacy which a similarity of pursuits ripened into a friendship that death only dissolved. He afterwards studied at the university of Paris, and subsequently at the Sorbonne. In 1612 he took the vows at the convent of the *Minimes*, in the neighbourhood of Paris, and the year following received ordination as priest, when he deemed it incumbent on him to study the Hebrew language, a thorough knowledge of which he acquired. In 1615 he filled the chair of philosophy at Nevers, and there taught till the year 1619, when he was chosen superior of the convent, and on completing the term of his office he travelled into Germany, Italy, and the Netherlands. He finally settled in Paris, where his gentle temper and his polite and engaging manners procured him a number of distinguished friends. Of these the chief was the founder of the Cartesian philosophy, who entertained the highest opinion of his abilities, and consulted him upon all occasions.

It has been stated—though the story seems highly improbable—that Descartes, by the advice of Mersenne, at once changed his intention of founding his system on the principle of a vacuum, and adopted that of a plenum. The discovery of the cycloid has been ascribed to him and also to Descartes, but it now seems pretty clear that to neither are we indebted for the first notice of this curve. [CYCLOID.] Mersenne died at Paris in 1648, in consequence of drinking cold water when over-heated. The result of this indiscretion was an internal abscess in the side, which he desired should be opened. The surgeon made the incision two inches below the right place, and the patient expired under the operation.

The Père Mersenne was undoubtedly a man of great learning and unwearied research, and deserved the esteem in which he was held by the philosophers and literati of his age; but, except his *Harmonie Universelle*, his works are now unread and almost unknown. If by some he was over-rated, by others he has been undervalued; and when Voltaire mentioned him as *le minime et très minime Père Mersenn*, he indulged his wit at the expense of one with whose writings, it is to be suspected, he was very little acquainted. His eulogist however, in the *Dictionnaire Historique*, admits that he very ingeniously converted the thoughts of others to his own use; and the Abbé Le Vayer calls him *le bon Larron*—a skilful pilferer. Nevertheless, the work above named, *L'Harmonie Universelle, contenant la Théorie et la Pratique de la Musique*, in 2 vols. fol., 1637, has proved of the utmost value to all later writers on the subject, and among the number, to the author of the present notice. Dr. Burney says of it, that notwithstanding all his 'partiality to his country, want of taste and method, there are (in the work) so many curious researches and ingenious philosophical experiments, which have been of the greatest use to subsequent writers, particularly Kircher, as render the book extremely valuable;' and Sir John Hawkins remarks, that 'the character of Mersennus as a philosopher and mathematician is well known in the learned world. To that disposition which led him to the most abstruse studies he joined a nice and judicious ear, and a passionate love of music: these gave a direction to his pursuits, and were productive of numberless experiments and calculations tending to demonstrate the principles of harmonics, and to prove that they are independent on habit or fashion, custom or caprice, and, in short, have their foundation in nature, and in the original frame and constitution of the universe.' The

work was, in 1648, translated into Latin and enlarged, by the author; but both the original and translation are now become as rare as they are curious to the antiquary and interesting to the musical inquirer.

MERSEY. [CHESHIRE; LANCASHIRE]

MERTHYR TYDVIL, or TYDFIL, a parliamentary borough and parish in the hundred of Caerphilly and county of Glamorgan, 18 miles south by east from Cardiff and 140 miles west-north-west from London (direct distances). The parish extends from north to south about 10 miles, and has an average breadth of three miles; comprising the hamlets of Forest, Garth, Gellidæg, Taff-and-Cynon, and Hoelch-Wormwood. Part of the hamlet of Forest and part of the hamlet of Taff-and-Cynon are not included within the limits of the parliamentary borough; with this exception, the borough is co-extensive with the parish. The town lies in a valley to the left of the Taff river, but the houses are so scattered that it is difficult to say where it either begins or terminates; indeed there is not in the whole parish what can be correctly denominated a street. The houses themselves are for the most part of a very mean description, consisting chiefly of the cottages of labourers, and beer and retail shops.

This place is said to take its name from Tydfil, or Tudfil, the daughter of the lord (regulus) of Garthmadrin, who was murdered here by a party of marauding Saxons. The church, subsequently erected near the spot, was dedicated to Merthyr Tydvil, or St. Tydvil the Martyr, in commemoration of the event. The present church is a neat edifice of recent erection. It is in the diocese of Llandaff, and the living, a rectory in the patronage of the marquis of Bute, has a net annual revenue of 675*l.* Besides the parish church there is a chapel-of-ease, called Dowlais Chapel. The assessed taxes of the parish, in the year 1830, amounted to 1587*l.* 13*s.* 1*d.*

Merthyr Tydvil was not represented in parliament till the passing of the 'Reform Act.' It now returns one member. The mining operations of this place were comparatively unimportant prior to the year 1755. About this time, experience having shown the importance of preparing iron by means of pit-coal, Mr. Anthony Bacon, member of parliament for Aylesbury, became the lessee of a considerable tract of land in the neighbourhood, and erected the first smelting-furnace at Cyfarthfa. During the American war that gentleman contracted with government for supplying the several arsenals with cannon, from which and other similar undertakings he ultimately realised a large fortune. At the close of the war the contract was transferred to the Carron works of Scotland, but in the mean time extensive works had been established at Pendarren and more particularly at Dowlais, in the hamlet of Hoelch-Wormwood. The latter place is now the seat of the immense smelting-furnaces of Messrs. Guest and Co., the largest in the empire. There are in all the parish twenty-four furnaces, and such has been their success, that in the year 1830 the quantity of iron produced in South Wales 'was estimated at 277,000 tons, while that made in Staffordshire and the rest of England did not materially exceed 300,000 tons.' (M'Culloch.)

The population of the parish, in 1831, was 22,083, but it is extremely fluctuating, a slight improvement or depression of the iron trade causing it to increase or decrease by thousands. A decrease of this description had taken place shortly before the taking of the last census, and it may therefore be presumed that the number above given is less than the average population. The market-days are Wednesday and Friday, and the fairs are held 13th May, 3rd September, 2nd December, and Trinity Monday.

(*Boundary, Population, and Church Revenue Reports; Beauties of England and Wales; M'Culloch's Statistical Account of the British Empire, &c.*)

MERTON COLLEGE, Oxford. This college was first founded at Maldon, in Surrey, in 1264, by Walter de Merton, bishop of Rochester and chancellor of England, who in 1274 removed it to Oxford.

Ela Longespé, countess of Warwick, is recorded to have been a benefactor to it about the year 1295: John Wyllott, D.D., chancellor of Exeter, gave exhibitions in 1380 for the maintenance of twelve portionists, called postmasters, who were afterwards increased to fourteen by John Chamber, fellow of Eton, who directed that his two additional exhibitioners should be elected from Eton College. Chalmers says, 'On the building of the chapel these postmasters offi-

ciated as choristers, and had a salary of six shillings and fourpence per annum for this service; but there was at that time no regular choir.' These exhibitioners, he adds, resided in a hall opposite to the college, which had been given to it by Peter de Abingdon, or Habendon, the first warden; and here they remained until the latter end of queen Elizabeth's reign, when they were taken into college. Henry Jackson, minor canon of St. Paul's, who died in 1727, and who had received his education at this college, founded four scholarships for natives of Oxford. His benefaction however, for whatever reason, did not pass into effect until the year 1753.

The foundation, at present, consists of a warden, twenty-four fellows, fourteen postmasters, four scholars, two chaplains, and two clerks. The natives of the following dioceses are not eligible to fellowships: viz. St. Asaph, Bangor, St. David's, Llandaff, Hereford, Chichester, Exeter, Rochester, Lichfield and Coventry, Chester, and Carlisle. In the election of a warden the fellows choose three of their number, whom they present to the visitor, the archbishop of Canterbury, who appoints one of them.

The preferment in the patronage of this college consists of the rectory of Gamlingay, in Cambridgeshire; the vicarage of Diddington, in Huntingdonshire; the vicarage of Eleham, in Kent; the rectories of Kibworth Beauchamp in Leicestershire, and Denton, in Norfolk; the vicarages of Embleton and Ponteland, in Northumberland; the rectories of Cuxham and Ibstone, in Oxfordshire; with the chapel of St. John the Baptist in Oxford, and the vicarage of St. Peter in the East, and the chapels of Wolvercot and Holywell; the rectory of Farley, and the vicarage of Maldon, with the chapel of Chessington, in Surrey; the rectory of Lapworth, and the vicarage of Great Wolford, in Warwickshire; and the vicarage of Stratton St. Margaret's, in Wilts.

Among the more eminent members of this society may be enumerated Duns Scotus; Bradwardine, and Islip, archbishops of Canterbury; Wicliffe, who was a fellow of Merton; George Owen, physician to Henry VIII.; Jewel, bishop of Salisbury; Sir Isaac Wake; Devereux, earl of Essex, the parliamentary general; Cressy, the Roman Catholic historian; Anthony à Wood, the Oxford historian; and Sir Richard Steele. Among the wardens, Dr. Chamber, another of Henry the Eighth's physicians; Sir Henry Savile; and Dr. Harvey, the discoverer of the circulation of the blood, have been the most conspicuous.

The buildings of this college consist of three courts; the outer one toward the street was rebuilt in 1589, except the tower and gate, which are of the fifteenth century. The most ancient part of the college was built by Sever and Fitzjames, two of the wardens, afterwards bishops. The chapel, at the west end of the outer court, is also a parish church, dedicated to St. John the Baptist. It contains, among other monuments, that of Sir Thomas Bodley.

The number of members of this college, December 31, 1838, was 135.

(*Gutch's Colleges and Halls of Oxford; Chalmers's History of the University of Oxford; Oxford University Calendar, 1839.*)

MERULIDÆ, Thrushes, a family of Dentirostral birds, placed by Mr. Vigors between the *Laniadæ*, or *Shrikes*, and the *Sylviadæ*, or *Warblers*. In the former family, he is of opinion that *Vanga*, Cuv., together with *Prionops*, *Laniarius*, and *Thamnophilus* of Vieillot, bring us in contact with the *Thrushes*, and that the extremes of the family will be found in *Graucalus* and *Ceblyperis* of Cuvier, which last has been latterly arranged with the *Thrushes*, and both of which, by their bills, in some degree depressed at the base, lead back to *Tyrannus*, and the other broad-billed groups which commence the family. Mr. Vigors feels inclined rather to leave *Ceblyperis* in its original station among the *Shrikes*, from the peculiarity of its tail-coverts, which form themselves into a kind of puffed-out cluster on the back.

'The family of *Merulidæ*,' continues Mr. Vigors, 'connected as above with the *Laniadæ*, comprises a considerable number of species and many natural genera; but which, like most of the *Insectorial* groups, have hitherto received but partial examination. The general views by which they seem to be allied among themselves, as far at least as can be judged from their present unorganised condition, may be stated as follows:—but with that expression of doubt which ever attends inquiries like the present, where the

absence of accurate information to the economy of the subjects before us, and of extensive knowledge of the forms connected with them, leaves us no better foundation for our inferences than partial conjecture. The genus *Myiothera*, Ill., seems to be the first group of the present family which is connected with the *Laniadæ*, where it is met by some of the smaller species of *Thamnophilus*. This group seems to lead by *Pitta*, Vieill., and perhaps *Cinclus*, Bechst., through some intervening forms, to the true *Thrushes*, or the genera *Turdus* of authors and *Merula* of Ray, which form the type of the family. To these we may add that portion of the Linnean Orioles, which, possessing the curved and notched bill of the *Thrushes*, constitutes the genus *Oriolus*, or true Oriole, of the present day. Here we meet several groups, generally arranged without order in the Linnean genus *Turdus*, and hitherto entirely uncharacterised, which gradually lead from the typical groups to those which possess a more generally delicate conformation; until the comparatively strong form and robust bill of the *Thrushes* is lost in the weaker body and more slender bill of the *Warblers*. Here again the group of *Rock Thrushes*, of which the *T. saxatilis* is the type, appear to bring us round, by their general habits and assimilating characters of bill and *tarsi*, to *Myiothera*, where we entered the family. Those birds which constitute the groups which we denominate *Chatterers*, and which form the genus *Ampelis* of Linnæus, are usually assigned a place near this family; and I must confess that, from the general affinity which they appear to bear to it, I have felt, and still feel, considerable doubt whether this be not their natural station. A strong affinity however on the other hand seems to unite them with the wide-gaped *Pipræ*, and some of those other groups which, by their bill, broad and depressed at the base, appear to come in contact with the earlier divisions of the present tribe, and the extreme of the *Fissirostres* which precede it. The general rule of placing groups in a continuous situation, according to what appears to be the predominance of their more important characters, has inclined me to arrange the birds of which I speak, provisionally among the *Pipridæ*, at the extreme termination of the tribe before us. In my present view of the case, the characters in which they accord with that family and approximate the extreme groups of the preceding tribe appear to predominate. More accurate knowledge on these subjects will clear away these and similar difficulties. But I cannot too often insist upon the point, that whatever alterations may take place hereafter in our ideas respecting the disposition of these subordinate groups, they cannot interfere with the general principles which it is the object of this inquiry to illustrate. Instead of impugning our general views, they will merely remove those doubts on minor points in which our present limited acquaintance with nature involves us.

In Mr. Swainson's 'Classification of Birds,' the reader will find elaborate details of his views respecting the affinities and analogies of this extensive family, which our limits do not permit us to give. The following is the arrangement in the Synopsis, where the family is placed between the *Laniadæ* and the *Sylviadæ*.

MERULIDÆ.

Subfamily *Brachypodince*.

Feet very short. Hind toe almost as long as tarsus. Claws short, much curved. Bill distinctly notched. Wings short, rounded. Feathers on the rump very long and thick-set. (Sw.)

Genera. *Micropus*. (Sw.)

Bill as long as the head, straight, somewhat conic, but the culmen gradually arched. Tarsus remarkably short, feathered beyond the knees. Lateral toes unequal; hinder as long as the tarsus. Wings moderate, the first quill almost spurious. Tail even. (Sw.)

Example, *Micropus chalconcephalus*, 'Pl. Col.,' 453. (Subgenus, *Hypsipetes* (Vig.). Tail forked. Example, *Hypsipetes pearoides* (Gould, 'Cent. Himala Birds').

Brachypus. (Sw.)

Bill shorter than the head; the base broad; the sides compressed; culmen elevated and curved from the base. Rictus generally furnished with bristles. Feet very short, strong; tarsal scales entire. Tarsus longer than the hind toe. Claws curved; broad, acute, wings and tail rounded. (Sw.)

Subgenera. *Brachypus* (Sw.). Bill short. Rictus bristled. P. C., No. 927.

Feet small, weak, lateral toes equal, hinder toe as long as the tarsus.

Example, *Brachypus dispar*, 'Pl. Col.,' 137.

Chloropsis (Jard. and Selb.). Bill more lengthened; the tip much hooked; the notch of the upper mandible forming a small distinct tooth. Rictus of gape smooth. Feet small, lateral toes unequal, the hinder toe rather shorter than the tarsus. (Sw.)

Example, *Chloropsis Malabaricus*, 'Pl. Col.,' 512, f. 2.

Jora, or *Jōra* (Horsf.). Bill nearly as long as the head, lengthened, somewhat conic, and rounded. Rictus smooth. Tarsus rather lengthened, the anterior scales divided. Middle and hinder toe of equal length. Tarsus much longer than either. Tail very short, fasciculated; the tips truncate and even.

Example, *Jora scapularis*, Horsf., 'Java.'

Andropadus (Sw.). Bill very short, resembling that of *Brachypus*, but the upper mandible crenated near the tip. Neck with setaceous hairs. Rictus bristled. Wings, tail, and feet as in *Brachypus*. (Sw.)

Example, *Andropadus vociferus*, 'Ois. d'Afr.,' 106, f. 2.

*Hæmatornis** (Sw.). Head crested. Bill short. Rictus bristled. Feet short, lateral toes unequal, hinder toe shorter than the tarsus, which is equal to the middle toe. Wings and tail rounded. (Sw.)

Example, *Hæmatornis chrysorrhæus*, 'Ois. d'Afr.,' 111, pl. 107, f. 2.

Tricophorus. (Temm.)

Culmen gradually arched. Nostrils and base of the bill surrounded with lengthened slender hairs. Gape very strongly bristled. Margins of the mandibles white. Feathers of the crown and chin elongated. Nape of the neck with several conspicuous lengthened bristles, considerably exceeding the surrounding feathers. Feet short. Tarsus longer than the hind toe, and feathered beyond the knees. Inner toe shortest. Wings and tail moderate, the former with the three first quills much graduated.

Example, *Tricophorus olivaceus*. (Swainson, 'Birds of West Africa,' i., 264.)

Phyllastrephus. (Sw.)

Bill as long as the head, strong, the tip rather hooked. Rictus strongly bristled. Frontal feathers small, compact, directed forwards, and compressed on the base of the bill. Wings and tail moderate, rounded. Feet short, strong, robust. Tarsus and middle toe of the same length; lateral toes unequal, the inner shortest; hinder toe shorter than the inner one. Anterior tarsal scales divided. (Sw.)

Example, *Phyllastrephus Capensis*, 'Ois. d'Afr.,' 112, f. 1.

Icteria. (Vieill.)

Bill with the general form of that of *Brachypus*, but the culmen more elevated and arched, and both mandibles entire. Wings and tail rounded. Tarsus considerably lengthened and strong. Inner toe the shortest; middle toe very long. Locality, America.

Example, *Icteria polyglotta*. (Wilson, pl. 6, f. 2.)

Subfamily *Myiotherinæ* (*Myiotherinæ*)—*Ant-Thrushes*.

Bill straight, somewhat cylindrical; the tip suddenly bent down or hooked.

Dasycephala. (Sw.)

Bill as long as the head, straight; tip abruptly hooked, base wide, the rest somewhat cylindrical. Gonyes strong, ascending. Nostrils and front defended by stiff feathers and bristles, pointing in different directions. Rictus strongly bristled. Tarsus lengthened, slender; lateral scales numerous, small, oval. Toes and claws slender; inner toe shortest; outer toe connected to the middle as far as the first joint. Hind claw large. Wings and tail rounded.

Example, *Dasycephala rufescens*. (Birds of Brazil, pl. 76.)

Myiothera. (Ill.)

Feet lengthened, rather stout. Lateral scales of tarsus in an entire piece. Claws not broad, nor greatly curved. Bill as in the small *Thamnophili*. Wings short. Tail moderate, rounded.

Subgenera *Myiothera*. Inner toe longer than the outer and cleft to its base; outer toe with its first joint united to that of the middle toe. The tarsus with the anterior scales divided.

Drymophila (Sw.). Inner toe shorter than the outer,

* N.B.—This name is preoccupied. [FALCONER, vol. x., p. 174.]

which is only slightly connected to the middle. Tarsus (typically) very smooth: all the scales entire. (Sw.)

Example, *Dryomphila longipes*. ('Zool.', Ill., ii. 23.)

Brachypteryx (Horsf.). See the article.

Myiocrincla (Sw.). Legs strong. Inner toe longer than the outer. All the tarsal scales divided. Anterior claws small; hinder claw nearly straight, and as long as the toe. (Sw.)

Example, *Myiocrincla Colma*, 'Enl.' 821.

Pithys (Vieill.). Feet syndactyle. The inner lateral toe shortest; the outer united by its first and second joint to the middle toe. All the tarsal scales entire.

Example, *Pithys albifrons*. Vieill., 'Gal.', pl. 129.

N.B. Mr. Swainson remarks that *Urotomus*, *Formicivora*, and all the other small *Myiotheræ*, having the feet weak and the tarsal scales and claws similar to those of *Thamnophilus*, he thinks it better to refer them to that group; but as it has not been analyzed, he does not, in the *Classification of Birds*, incorporate those two subgenera, although proposed by himself some years ago. See *Zoological Journal*, vol. i., p. 301; and the paper *On the Natural Affinities that connect the Orders and Families of Birds*, by Mr. Vigors, who refers to Mr. Swainson's memoir in the 'Zoological Journal,' and observes that the reader may there see the line of connexion between *Thamnophilus* and *Myiothera* fully established by the intervention of several forms gradually passing into each other, such as *Formicivora*, *Urotomus*, and *Dryomphila*. (Linn. Trans., vol. xv.)

Pitta. (Temm.)

Bill strong, thrush-like: the culmen gradually curved. Nostrils nearly naked. Wings moderate; the first and second quills but slightly graduated. Tail remarkably short, almost hid by the covers. Feet very long, pale, the scales nearly entire. Inner toe slightly shorter than the outer. India and Australia. (Sw.)

Example, *Pitta gigas*. 'Pl. Col.' 217.

Subgenera *Chlorisoma* (Sw.). Bill as in *Pitta*, but somewhat thicker. Nostrils protected and nearly covered by incumbent feathers. Rictus bristled. Wings rounded; the four first quills much graduated. Tail moderate or lengthened, graduated. Feet strong, rather lengthened: the inner toe scarcely shorter than the outer.—India. (Sw.)

Example, *Chlorisoma thalassina*. 'Pl. Col.' 401.

Grallaria (Vieill.). Bill thrush-like, as in *Pitta*. Wings rounded; the two first quills graduated, the first half as long as the second, the three next nearly equal. Tail short and rounded. Legs very long: the tarsus slender, pale; the anterior scales divided, the lateral scales (typically) entire. Lateral toes nearly equal.

Example, *Grallaria Rex*. 'Enl.' 702.

Mr. Swainson remarks that it appears to him that *Chamaeza*, Vig., is more an aberrant species of *Grallaria* than a distinct type in the genus *Pitta*: the only species known chiefly differing in having the tail longer and the lateral scales divided.

Cinclus. (Bechst.)

Bill moderate, rather slender, very straight, considerably depressed; tip absolutely notched; gonys ascending. Nostrils naked, membranaceous; the aperture very small and linear. Wings moderate, rounded; the first quill spurious. Tail very short, even. Feet large, very strong, pale; the lateral toes equal; tarsal scales entire and smooth. (Sw.)

Example, *Cinclus albicollis*. Selby, pl. 45.

Subfamily Merulinæ. True Thrushes.

Wings more lengthened and pointed. Bill notched, with the culmen gradually curved to the tip, which is bent, but not hooked, over the lower mandible. Feet formed both for perching and walking. (Sw.)

Petrocincla. (Vig.) Rock Thrushes.

Bill thrush-like: tip of the upper mandible abruptly bent down and nearly entire. Wings moderate; the first quill spurious; the second shorter than the three next, which are equal and longest. Tail even. Anterior scales divided. Lateral toes equal. Claws small, but slightly curved.

Example, *Petrocincla montana*. 'Ois. d'Afr.' pl. 101.

Subgenus *Petrophila* (Sw.). Bill thrush-like: the culmen and tip of the upper mandible gradually bent and entire. Wings and tail as in the last. Legs pale; anterior scales entire. Lateral toes unequal; inner shortest. Claws moderate and fully curved. (Sw.)

Example, *Petrocincla cyanocephala*. (Gould, 'Cent. of Himal. Birds.')

Merula. (Willughby.)

See the article BLACKBIRD.

Orpheus. (Sw.)

General structure of *Merula*. Bill more curved in the culmen; the notch small, or nearly obsolete. Rictal bristles rather strong. Wings rounded; the three first quills graduated. Tail lengthened, graduated, or rounded. Inner toe manifestly shorter than the outer.

Example, *Orpheus Polyglottus*. Wilson, pl. 10, f. 1.

Subgenus *Cossypha*, Vig. General structure of *Orpheus*, but the wings more rounded, and the tail less so. Rictus smooth. Africa only.

Example, *Cossypha leucocephala*. (Sw., 'Birds of West Africa,' 1, pl. 32.)

Chætops. (Sw.)

Bill moderate, thrush-like, notched. Nostrils basal, large, naked, membranaceous; the aperture lateral and linear. Frontal feathers rigid; the shafts composed of bristles. Chin feathers the same, but weaker. Rictus bristled. Wings very short and rounded. Tail rather lengthened, broad, convex, soft, and slightly rounded. Tarsi very long and strong: anterior scales divided. Lateral toes unequal. Claws small, obtuse, and slightly curved; the three anterior of equal size.—Africa. (Sw.)

Example, *Chætops Burchellii*, Pl. 'Col.' 385.

Subfamily Crateropodinae. Rabblers.

Legs remarkably long and strong, with the claws but slightly curved. Wings short and rounded. Tail large, broad, graduated, and very soft. Plumage lax. Bill compressed, straight, hard; the tip nearly entire. (Sw.)

Pellorneum. (Sw.)

Bill moderate, straight, somewhat conic; tip notched; gonys ascending. Frontal feathers small, rigid, directed forwards. Rictus bristled. Wings very short, much rounded. Tail moderate, graduated. Tarsus and middle toe of equal length; lateral toes much shorter, and equal; hinder toe shorter than the tarsus. Anterior claws very small, and but slightly curved. Tarsal scales hardly divided. (Sw.)

Example, *Pellorneum ruficeps*.

Crateropus. (Sw.)—(Lanthocincla—part.)

Bill nearly as long as the head; more or less straight from the base; much compressed; absolutely notched. Rictus bristled. Frontal feathers rigid. Wings short, rounded. Tail large, broad, soft, and rounded. Feet very large and strong. Tarsus lengthened; the anterior scales divided. Lateral toes nearly equal; hind toe large, nearly as long as the middle toe. Plumage lax, soft. (Sw.)

Example, *Crateropus Reinwardii*. ('Zool.' Ill., i. 30.)

Grallina. (Vieill.)

Bill slender, straight, rather cylindrical above; the sides very little compressed; base broader than high; tips of both mandibles distinctly notched. Nostrils naked, basal. Rictus with a few bristles. Wings very long; first and second quills graduated, four next longest. Tail lengthened, even. Feet strong, formed for walking, black; anterior toes divided, the rest entire. Lateral toes equal; middle toe and claw short, very little longer than the hind-toe.—Australia.

Example, *Grallina melanoleuca*. Vieill., 'Gal.' pl. 150.

Subgenus *Cinclosoma* (Horsf. and Vig.). Bill very straight; culmen and gonys equally curved towards the point, which is slightly notched. Wings very short; the two first quills graduated; the three next longest, and of equal length. Tail lengthened, broad, graduated; the feathers narrowed towards their tips. Under-tail coverts very long. Feet moderate; inner toe longer than outer. Australia. Analogous to *Accentor* among the *Sylviadæ*. (Sw.)

Example, *Cinclosoma punctata*. (Shaw, 'Zool. of N. H.' pl. 9.)

Malacocircus. (Sw.)

Bill more or less curved, by being elevated at the base, having the sides much compressed, and the culmen high and arched; the tip almost entire, and not suddenly bent over the lower. Feet very large. Tail soft, graduated, generally lengthened. (Sw.)

Example, *Malacocircus striatus*. ('Zool.' Ill., ii., pl. 127.)

Subgenera *Megalurus* (Horsf.). Bill slender. Rictus

bristled. Wings very short; the two first quills graduated, the four next all of the same length, and longest. Tail lengthened, graduated; the feathers narrow. Feet very large and strong. Toes lengthened; the inner toe rather longer than the outer. Claws slender, and but slightly curved. Anterior scales divided, lateral, entire.

Example, *Megalurus palustris*.

Pomatorhinus (Horsf.). General structure of *Crateropus*; but both mandibles of the bill curved and entire, and the wings shorter and much more rounded; four first quills graduated. Tarsal scales entire. Inner toe rather shorter than the outer.

Example, *Pomatorhinus montanus*.

Timalia (Horsf.). Plumage lax. Bill straight, rather short, much compressed; culmen high and arched gradually; tip obsoletely notched or entire; commissure curved. Wings short, rounded. Tail more or less lengthened, graduated. Feet strong. Lateral toes nearly equal.—India, Australia, Africa. (Sw.)

Example, *Timalia thoracica*. ('Pl. Col.,' 76.)

Pteroptochus. (Kittlitz.)

Feet of extraordinary size and thickness; all the anterior toes nearly equally long; claws long, slender, slightly curved. Tail consisting of fourteen feathers, rounded and carried erect. Wings very short. Representing *Menura* and *Orthonyr*.—Western Tropical America only. (Sw.)

Example, *Pteroptochus megapodius* (Kittl., pl. 4. 'Zool.,' Ill., ii., pl. 117.)

Subfamily *Oriolinæ*. Orioles.

Bill thrush-like, as long as the head, broad at the base, compressed beyond; the base and gape devoid of bristles. Nostrils naked; aperture large. Wings lengthened. Rump feathers thick. Lateral toes unequal. (Sw.)

Donacobius. (Sw.)

Habit and general structure of *Crateropus*. Bill lengthened, slender; the culmen arched from the base; the tip hooked and notched. Nostrils large, naked, membranaceous; the aperture large, oval, terminal. Wings remarkably short, and rounded. Tail moderate, broad, cuneated. Feet very large and strong. Lateral toes equal; claws slender, acute, slightly curved.—America only. (Sw.)

Example, *Donacobius vociferans*. ('Zool.,' Ill., ii., pl. 72.)

Sericulus. (Sw.)

Bill rather stout, resembling that of *Oriolus*. Nostrils naked. Wings moderate; two first quills equally graduated; third nearly as long as the fourth. Tail moderate, even. Feet strong, robust. Tarsus much longer than hind toe; inner shortest.—Australia. (Sw.)

Example, *Sericulus chrysocephalus*. (Lewin's 'Birds of New South Wales,' pl. 1.)

Oriolus. (Linn.)

Bill as long as the head; broad at the base; tip distinctly notched, and somewhat hooked. Nostrils short, nearly naked; aperture lateral, large, and oval. Wings rather lengthened; first quill very short; second not quite so long as the third, which is generally the longest. Tarsus rather short, longer than the hind toe and claw; anterior scales divided.—Old World. (Sw.)

Example, *Oriolus Galbula*. ('Enl.,' 26.)

Subgenus *Irena* (Horsf.). Bill of *Oriolus*; but the culmen much raised and considerably arched from the base, rather hooked at the tip. Nostrils partly defended by short plumes, which cover the membrane. Rictus slightly bristled. Wings and tail as in *Sericulus*. Feet small. Tarsus very short, scarcely longer than the hind toe and claw; anterior and lateral scales entire. Inner toe rather shortest. Rump feathers very thick, and slightly spinous.—India.

Example, *Irena Puella*. (Horsf., 'Java.' 'Pl. Col.,' 70.)

Dulus. (Vieill.)

Bill very short, much compressed, but with the culmen elevated and arched. Commissure curved. Nostrils as in *Oriolus*. Wings rather short; first quill not half so long as the second; third, fourth, and fifth longest; secondaries with the tips notched; tertiaries lengthened. Tail moderate, slightly forked. Feet as in *Oriolus*. Claws strong, broad, much curved.—South America.

Example, *Dulus palmarum*. ('Enl.,' 156, f. 2.)

Sphecothes. (Vieill.)

Bill rather short, strong, partaking of the structure both

as *Dulus* and *Oriolus*; the base broad; commissure straight, gape very wide, extending beyond the eye. Nostrils naked, the aperture large and oval. Wings, tail, and feet as in *Dulus*. Tarsus hardly longer than the hind toe and claw. Australia.

Example, *Sphecothes viridis*. (Vieill., 'Gal.,' pl. 147.)

M. Lesson, in his 'Table Méthodique,' makes the *Turdus* sinées, the fifth family of the Denti-rostral birds, consist of the following genera:—

Turdus (Linn.), including *Merula*, *Turdus*, and *Ixos*; *Cinclus*; *Cinclosoma*; *Dulus*; *Sturnella*; *Timalia*; *Dasyornis*; *Jora*; *Pitta*; *Myiothera*; *Brachypteryx*; *Gralina*; *Acridotheres*; *Psaroides*; *Mimetes*; *Oriolus*; and *Sericulus*. The position assigned to the family is between the *Ampelidées* and the *Menurées* (*Mænura*).

The Prince of Musignano, in his 'Geographical and Comparative List of the Birds of Europe and North America' (1838), places the '*Turdidæ*' between the '*Certhidæ*' and the '*Muscicapidæ*', and assigns to the first the following subfamilies and genera.

Subfam. a. *Calamoherpinae*.

Genera—*Cettia* (Bonap.); *Pseudo-luscinia* (Bonap.); *Locustella* (Ray); *Calamodyta* (Bonap.); *Cysticola* (Less.); *Erythropgia* (Smith, *Agrobates*, Sw.); *Calamoherpe* (Meyer); *Hippolais* (Brehm.). These are for the most part formed at the expense of the genera *Sylvia* and *Motacilla* (Linn.).

b. *Sylvinae*.

Phyllopus (Meyer, *Phylloscopus*, Boie); *Melizophilus* (Leach); *Sylvia* (Lath.); *Curruca* (Brisson); *Nisoria* (Bonap.); *Accentor* (Bechst.); *Calliope* (Gould); *Luscinia* (Br., *Philomela*, Sw.).

c. *Saxicolinae*.

Dandulus (Boie, *Erythaca*, Sw., *Rubecula*, Br.); *Ruticilla* (Br., *Phenicura*, Sw.); *Saxicola* (Bechst.); *Vitiflora* (Briss., *Ceanthe*, Vieill.); *Sialia* (Sw.); *Petrocincla* (Vig., part); *Petrocossyphus* (Boie)

d. *Oriolinae*.

Oriolus (Linn.).

e. *Turdinae*.

Merula (Ray); *Turdus* (Linn.); *Oreocincia* (Gould); *Mimus* (Boie, *Orpheus*, Sw.); *Cinclus* (Bechst.).

f. *Motacillinae*.

Anthus (Bechst.); *Budytes* (Cuv.); *Motacilla* (Linn.).

g. *Parinae*.

Regulus (Ray); *Parus* (Linn.); *Mecistura* (Leach, *Psaroides*, Brehm.); *Calamophilus* (Leach, *Mystacinus*, Brehm.); *Egithulus* (Vig., *Pendulinus*, Cuv.).

h. *Sylvicolinae*.

Parula (Bonap.); *Trichas* (Sw.); *Vermivora* (Sw.); *Seiurus* (Sw.); *Sylvicola* (Sw.); *Wilsonia* (Bonap.); *Culicivora* (Sw.).

We have thus endeavoured to lay before the reader the views of some of the leading ornithologists respecting the arrangement of the *Thrushes*. The student will find a very extensive and well-arranged collection of the family in the museum of the Zoological Society of London.

MERU'LIUS, a genus of Fungi, deriving its name from *Merula*, a blackbird, some of the species being black. The character of the genus is to have a woody or sinuous plaited hymenium, with the folds confluent with the pileus, and forming angular unequal perforations. Its only interest is derived from one of the species being a common cause of dry-rot. This plant, the *Merulius lachrymans* of Fries, and the *Boletus lachrymans* of Sowerby's 'Fungi,' t. 113, is very common on rotten wood in vaults and cellars, among the timbers of ships, and in similar damp situations where there is not a free circulation of air. In general it is found without fructification, its thallus, or spawn, being the only part developed, and resembling a white, dry, cottony matter, consolidated into a substance like leather. The fructification is composed of fine yellow orange or reddish-brown plicæ, so arranged as to have the appearance of perforations, and occasionally producing 'pendent processes like inverted cones;' it usually forms a circle varying from one to eight inches in diameter, and when perfect the cavities contain drops of clear water, which have given rise to the specific name. The only known means of preventing the attacks of this and other fungi upon timber is a free circulation of dry air, or the impregnation of wood with corrosive

sublimate, a process now called Kyania ng, after Mr. Kyan, who invented it.

MERVILLE. [NORD.]

MERYCOTHE'RIUM, the name applied by M. Bojanus to a genus of fossil *Mammalia*, founded on three fossil teeth, according to the authority of the person who sold them to him. Bojanus records one species under the name of *Merycotherium Sibiricum*.

Cuvier (*Oss. Foss.*) remarks that if these teeth are really fossil, and from Siberia, this would be the first authentic example of such remains belonging to the genus *Camelus*. He observes that their size, their form (which is longer than it is wide), and the absence of an 'arête,' or small cone, between the columns, leave no doubt as to their generic character. Those of the Giraffe are more square, and with a small point, as in the stags; while those of the Ox have a cylindrical 'arête,' or ridge. Cuvier further states that Bojanus, who has very well remarked this general resemblance, has also noticed some differences which have appeared to him sufficient to justify a new name for the animal; but the French zoologist observes that Bojanus proposes this distinction with doubt, and declares his readiness to renounce it, if it should be established that those teeth belonged to a camel, a gigantic sheep, or an antelope (the only genera in fact which want ridges between the columns).

Cuvier thinks that the differences of which Bojanus speaks are owing to the skulls of the Camels examined by the latter, as points of comparison, being the heads of individuals much older than that to which the teeth in question belonged. A Dromedary only a little older, and whose teeth were nearly in the same state of detrition, appeared to Cuvier to present no difference, save that of individuality. He remarks that they are, as Bojanus truly pointed out, the penultimate and antepenultimate molars of the left side of the upper jaw, and that it remains to show in what beds they were found, and to search for other bones of the animal, in order to see whether they will furnish any specific character. Cuvier concludes by stating that M. Marcel de Serres, professor of mineralogy at Montpellier, had just communicated to him a drawing of a fossil femur from the environs of that city, which resembled much, in the parts of it which were preserved, that of a Camel. [CAMEL, vol. vi., p. 191.]

Notwithstanding Cuvier's opinion, which is worthy of all respect, there are those who still think that *Merycotherium* is a distinct genus. See Bojan., 'Nov. Act. Acad. Leop. Nat. Cur.' xii., tab. 21, f. 1-8.

MERZLIAKOV, ALEXIUS PHEDOROVITCH, a Russian writer, more distinguished as a critic than as a poet, though not without talent in the latter character, was born at Dalmatova, in the government of Perm (where his father was a wealthy merchant), in 1778. In his fourteenth year he recommended himself to Catherine II. by an ode on the peace with Sweden, and the empress ordered him to be sent to the university of Moscow, where he was placed under the charge of Kheraskov [KHERASKOV], and in 1798 was made professor of eloquence and poetry. In 1805 he quitted Moscow for the northern capital, where he held a similar professorship in the university. It was at St. Petersburg that, at the suggestion of Prince Galitzin, he commenced a popular course of lectures on literature, which were numerous attended, and obtained for him a high reputation with the public. These lectures, which were held twice a week during the winter at Galitzin's house, were then a novelty, and were the more interesting to his auditors, because the critic discussed at length the merits of the principal Russian poets and prose-writers.

His own productions consist chiefly of translations, among which are Aristotle's 'Poetic,' Virgil's 'Eclogues,' select scenes from the Greek tragedians, Eschenburg's 'Theory of Literature,' and Tasso's 'Gierusalemme.' Among his original poems, his shorter lyric pieces and songs are the best, the latter more especially, for they breathe strong national feeling, and have accordingly acquired more than a transitory popularity. Merzliakov died in 1826 or 1827.

MESA'PUS. (Zoology.) [SALICOQUES.]

MESEMBRYA'CEÆ, a natural order of Polypetalous Exogens, consisting of herbaceous and shrubby plants inhabiting various parts of the world, in very dry temperate climates, but especially the Cape of Good Hope, where the species are extremely numerous. They are succulent plants, with an inferior, many-celled, polyspermous ovary, numerous narrow petals, indefinite stamens, and a fruit

splitting into regular stellate valves. The common Ice-plant of the gardens, *Mesembryanthemum crystallinum*, so called because its cuticle is elevated in the form of multitudes of crystalline points, is burnt in the Canaries for the sake of its ashes, which the Spaniards import in large quantities for their glass-works under the name of *Barilla Moradera*. Another species, the *M. nodiflorum*, is used in Egypt for the same purpose, and also in the manufacture of Morocco leather. This and the other species are chiefly found in sandy, desert, arid places, where they flourish in the absence of other vegetation, and afford a grateful food to cattle, which browse upon them. *M. emarcidum*, according to Burnett, is fermented by the Hottentots, when it becomes narcotic, and is chewed by those people like tobacco. Only four genera seem admissible into the order; the others referred to it under the name of Ficoideæ chiefly belonging to Tetragoniaceæ; but *Mesembryanthemum*, one of the admitted genera, alone comprehends more than 300 species.

Mesembryanthemum albidum,

1, a ripe fruit; 2, a vertical section of a flower.

MESENTERI'PORA. [POLYPIARIA MEMBRANACEA.]

MESENTERY is the membrane by which the intestines are attached to the posterior wall of the abdomen. It consists of a double layer of fine cellular and adipose tissue, which is attached to the abdominal wall by a comparatively narrow origin, and becoming gradually wider, spreads out like a fan, to be attached to the whole length of the canal of the small intestines. Between its layers the arteries pass to the intestines, and the veins and lacteals return from them.

The other abdominal organs are attached to the walls of that cavity and to each other by layers of membrane similar to the mesentery. Those which belong to the colon are called the meso-colon; those of the rectum the meso-rectum, &c.; while those which connect the stomach with the spleen and liver are named respectively the gastro-splenic and the gastro-hepatic, or lesser omentum.

MESMER. [ANIMAL MAGNETISM.]

MESODESMA, M. Deshayes's name for a genus of *Veneridæ* (*Erycina*, Lam.).

MESOLABIUM, an old name for any geometrical construction or proportion for finding two mean proportionals between two given lines.

MESOLE occurs massive and globular or reniform. Structure radiating from a centre, fibrous, foliated. Hardness 3.5. Colour white, greyish, or yellowish white. Translucent. Lustre pearly or silky. Specific gravity 2.35 to 2.4. It is found in Sweden and the Faroe Islands.

Analysis by—

	Hisinger.	Berzelius
Silica	42.17	42.60
Alumina	27.00	28.00
Soda	10.19	5.63
Lime	9.00	11.43
Water	11.77	12.70
	100.13	100.36

MESOLITE (Needle-stone) occurs crystallized and massive. Primary form a right rhombic prism. Cleavage parallel to the lateral faces of the primary form. Fracture conchoidal, uneven. Scratches fluor-spar, and is scratched by felspar. Colour white. Lustre vitreous. Transparent. Specific gravity 2.25.

Before the blow-pipe it becomes opaque, swells, and often fuses into a colourless glass; with borax it fuses difficultly.

It occurs in Iceland, Greenland, Finland, &c.

Analysis by—

	Fuchs and Gehlen.	Berzelius.
Silica	47.0	45.80
Alumina	25.9	26.50
Lime	9.8	9.87
Soda	5.4	5.40
Water	12.3	12.30
	100.4	99.87

MESOMPHYX, M. Rafinesque's name for a genus which he proposes to separate from *Helix* of authors.

MESOPOTAMIA (*Μεσποταμία*, called in the Old Testament *Aram-naharaim*, אֲרָם נַהָרַיִם, that is, 'Aram,' or 'Syria between the two rivers'), the antient name of the country lying between the Tigris and Euphrates, was bounded on the north by Mount Masius (*Karajeh Dagh*), a branch of Mount Taurus, and on the south by the Median wall and the canals which connected the Tigris and Euphrates, by which it was separated from Babylonia. (Strabo, xv., p. 746, Casaubon; Ptol., v. 18; Plin., v. 13, vi. 9.) The name of Mesopotamia, which was never employed to designate any political division, did not come into use till after the time of the Macedonian conquest of Asia. The southern part of Mesopotamia Xenophon calls Arabia (*Anab.*, i. 5, § 1); and other writers included it, especially the northern part, under the general name of Syria. (Strabo, p. 737.) It was considered by the Romans a division of Syria. (Mela, i. 11; Pliny, v. 13.) It is called by the Arabs in the present day *Al Jezira*, 'the island.'

Mesopotamia may be divided into two parts, the physical features of which differ greatly. The northern part, from Mount Masius to about 35½° N. lat., is a fertile country watered by the Chaboras and the Mygdonius; the southern part, from the neighbourhood of Circesium to the Median wall, is a flat and desert country, which Xenophon has described in the 'Anabasis.' 'The country,' he says, 'was a plain throughout (i. 5, § 1, 2), level as the sea, and full of wormwood (*ἀψιθίου*); whatever other shrubs or reeds it contained had all a sweet aromatic smell, but there was no timber in it. There were all kinds of wild animals in it; the most numerous were wild asses, and not a few ostriches; there were also in it bustards and antelopes.' It was inhabited in the time of Pliny and Strabo by predatory tribes of Arabs called Scenitæ, who were afterwards known under the name of Saracens. (Strabo, xvi., p. 747; Pliny, vi. 28, xxiii. 6.)

Little is known of the history of Mesopotamia till it became a province of the Persian empire. *Cushan-rishthaim*, who is mentioned in *Judges* (iii. 8, 10) as king of Mesopotamia, appears to have been only a petty prince of a district east of the Euphrates. In the time of Hezekiah the different states of Mesopotamia were subject to the Assyrians (2 *Kings*, xix. 13), and subsequently belonged in succession to the Chaldean, Persian, and Syro-Macedonian monarchies.

The northern part of Mesopotamia was divided into two parts by the river Aborras or Chaboras (*Khabour*), called Araxes by Xenophon (*Anab.*, i. 4, § 19), which rises in Mount Masius, and receiving the Mygdonius (*al Hual*) on the east, flows into the Euphrates at Circesium. Of these divisions the western was called Osroene, and the eastern Mygdonia.

The chief town of Mygdonia was Nisibis, also called Antiochia Mygdonica (*Nisibin*), situated on the river Mygdo-

nus, in the midst of a fertile plain at the foot of Mount Masius. It was surrounded by three brick walls, and was very strongly fortified. Sapor was repulsed in three separate attacks upon the town, A.D. 338, 346, 350; but it was ceded to him by treaty in 363. The Zoba of the Old Testament (1 *Sam.*, xiv. 47; 2 *Sam.*, viii. 3) is supposed to be the same town as Nisibis, since the Syriac writers frequently mention Nisibis under the former name. To the north of Nisibis was Daras (*Dara*), which was fortified by Anastasius I. (A.D. 506), who gave to it the name of Anastasiopolis. (Procop., *Pers.*, i. 10.) According to Niebuhr, there are considerable ruins both of Nisibis and Daras.

The chief town of Osroene was Edessa (*Orsa*), in the north-west of the province, nine geographical miles from the Euphrates. This town, which was also called Antiochia and Callirrhoe (Plin., v. 21), is supposed to be the Erech (עֲרֵךְ) of the Old Testament. (*Gen.*, x. 10.) Edessa suffered greatly by an earthquake in the time of Justinian, who rebuilt a considerable part of the town, and gave it the name of Justinopolis. Orsa was plundered by the army of Timur in 1393; but it soon recovered its former importance. It contains at present about 40,000 inhabitants; and is about three miles in circumference.

At the distance of two days' journey, according to Niebuhr, south-east of Orsa, was the antient town of Charræ (*Harran*), the Haran (חָרָן) of the Scriptures, where Abraham's family dwelt after they had left Ur of the Chaldees. (*Gen.*, xi. 31; xii. 5; xxvii. 43; xxviii. 10; xxix. 4.) In the time of Hezekiah, Haran had been conquered by the Assyrians. (2 *Kings*, xix. 12; *Is.*, xxxvii. 12.) It is mentioned by Ezekiel as a place of commercial importance (xxvii. 23). Charræ is memorable in Roman history for the defeat of Crassus. (Dion. Cassius, xl. 25; Pliny, v. 21; Lucan, i. 104.)

Circesium (*Kerkesiah*), at the union of the Euphrates and Aborras, was a very antient town: it is called Carchemish (כַּרְכַּמִּישׁ) in the Old Testament. (*Is.*, x. 9; *Jer.*, xli. 2; 2 *Chron.*, xxxv. 20.) It was strongly fortified by Diocletian. (Ammian., xxiii. 5.) A little to the north of Circesium, near Thapsacus, was an antient ford across the Euphrates.

MESOTYPE (Natrolite) occurs crystallized and massive. Primary form a right rhombic prism. Cleavage parallel to the primary faces. Fracture conchoidal, uneven. Scratches calcareous spar. Some crystals become electrical by friction. Colour white, with shades of grey, yellow, and red; colour of streak white. Lustre vitreous. Translucent, transparent. Specific gravity 2.219. *Massive varieties* globular and reniform. Structure fibrous, diverging. Lustre pearly.

By the blow-pipe fuses with ebullition into a spongy enamel. Gelatinizes in nitric acid.

Found in Ireland, Scotland, Iceland, the Faroe Islands, &c., in trap, basaltic, and porphyritic rocks, and also in the cavities of the more antient lavas of Vesuvius.

Analysis of a specimen from Faroe by Smithson:—

Silica	49.0
Alumina	27.0
Soda	17.0
Water	9.6

MESPILUS is a genus of Pomaceous plants, distinguished from *Pyrus* by the putamen of the carpels being bony, and their points spread open so as to give the fruit a cup-shaped appearance. In this restricted sense it is confined to those fruit-trees which are vulgarly called Medlars, whose astringent fruit does not become eatable till it has begun to arrive at that stage of decomposition which is called *bletting*. The word *Mespilus* has however been sometimes employed as a general name for all Pomaceous plants whose fruit has a hard putamen; it was used in this sense by Dioscorides, whose *μέσπιλον ἄρωνία*, or *τρικοκκόν*, was either *Cratægus tanacetifolia*, as Sibthorp believed, because he found that species still called *τρικοκκία* by the modern Greeks, or *C. Aronia*, as Sprengel conjectures; while his *μέσπιλον ἑτερόν*, or *ἐπιμηλίδα*, was the modern *Mespilus germanica*, or common cultivated medlar.

There are only two species of *Mespilus* proper the one *Mespilus grandiflora*, an ornamental tree common in shrubberies; the other *M. germanica*, a native of the woods

and wild places of middle and southern Europe, which furnishes all the varieties of *Medlar*. These are the Large Dutch, the Nottingham or Common, and the Stoneless. The first is preferred on account of its large size, but the Nottingham possesses the finest acidity; the Stoneless is easily distinguished by its small size and the character implied by its name. The trees may be propagated by either grafting or budding upon their own species, or upon the White Thorn, Quince, or Pear. By adopting the Pear as a stock, the straightest stems can be obtained. The branches of the Medlar naturally assume so tortuous an appearance, that any attempt to produce uniform regularity by pruning would only produce injurious effects. Pruning should be performed only with a view to general symmetry, the balancing of the top (which is apt to incline all to one side), and a judicious thinning where the branches are overcrowded. It is necessary to observe that the fruit is produced at the extremities of the branches, and therefore in pruning they must not be shortened.

The fruit, when first gathered, is extremely austere; but this austerity is changed soon after gathering into an agreeable acidity. When in a soft pulpy state, it is fit for use, and, preserved by the tough skin, will continue so for some time; but a sort of mouldiness generally makes its appearance at the stalk, and as soon as it is observed the fruit may be pronounced unfit for use. Dipping the stalk in brine would doubtless prove of advantage in preventing the attack of fungi on that part.

Mespilus japonica, the Loquat, is now called *Eriobotrya japonica*, *Mesp. Amelanchier* is *Amelanchier vulgaris*, and *M. Cotoneaster* is *Cotoneaster vulgaris*.

MESSALINA. [CLAUDIUS NERO.]

MESSALLA, or with his full name, MARCUS VALERIUS MESSALLA CORVINUS, was born B.C. 59, in the same year as Livy. It would appear from a passage in Cicero's letters that he went to Athens in his fifteenth year to study. (*Ep. Att.*, xii. 32.) He was opposed in early life to the party of Antony and Octavianus (Augustus), and was in consequence included in the proscription of the second triumvirate, B.C. 43 (*Dion.* xlvii. 11; *App.*, *Civ.*, iv. 38); but after the battle of Philippi, he contrived to make his peace with the conquerors, and was subsequently advanced by Augustus to offices of great trust and power. He accompanied Augustus in his campaign against Sextus Pompeius, B.C. 36, and on his return to Rome was made augur for the services he had rendered in that war. The military talents of Messalla appear to have been highly valued by Augustus; in B.C. 34, he subdued the Salassi and other warlike tribes which inhabited the Alps; and four years afterwards he conquered the Aquitani, to which victory Tibullus frequently alludes (*i.* 7; *ii.* 1, 33; *ii.* 5, 117). In the two following years he was sent by Augustus to Egypt and various parts of Asia on important public business; and on his return, B.C. 27, he obtained the honours of a triumph on account of his conquest of Aquitania. He was consul B.C. 31, and was appointed prefect of Rome B.C. 26. He died about A.D. 11.

Messalla was one of the most celebrated orators of his time; he is frequently mentioned by Quintilian in terms of the highest praise (*Inst. Orat.*, x. 1; compare *Hor.*, *Sat.* i., 10, 29; *Ars Poet.*, 370); and the author of the dialogue *De Oratoribus* considers him even superior to Cicero in grace and elegance of expression (*c.* 18). Messalla also appears to have paid attention to the study of language, since Quintilian informs us that he had not only written treatises on separate words, but even on separate letters. (*Inst. Orat.*, i. 7; compare *ix.* 4.) He was a great patron of literature in general, and appears to have conferred no small benefits on Tibullus, who frequently celebrates the praises of his patron with as much subserviency as the other poets of the Augustan age.

MESSENE. [MESSENIA.]

MESSENGERS, KING'S, certain officers employed under the secretaries of state, who are kept in readiness to carry despatches both at home and abroad. They are not now so often employed as formerly in serving the secretaries' warrants for the apprehension of persons for high-treason or other grave offences against the state. Formerly too it was not unusual for them to keep the prisoners they apprehended at their own houses. A remarkable instance of this practice is detailed in the 'Post-Boy' newspaper of 1713. London, Jan. 10.—Yesterday morning the Morocco ambassador was taken into the custody of one of her majesty's

messengers, by way of reprisal for his master's ordering and committing to slavery several of her majesty's subjects.' In the same paper, July 14, 1713, we read, 'The emperor of Morocco having released those of her majesty's subjects that had been carried into slavery, Don Bentura de Zari, his ambassador, who was in custody of Mr. Chapman, the messenger, by way of reprisal, was on Saturday last set at liberty.' So that his excellency must have passed six months in the messenger's custody.

MESSE'NIA (*Messēnia*), a country of antient Greece, was bounded on the east by Laconica, on the north by Elis and Arcadia, and was surrounded by the sea on the western and southern sides. It was separated from Laconica by the mountain-chain of Taygetus; and from Elis and Arcadia by the river Neda and the high land which runs between the bed of the Neda and the sources of the Pamisus. [ARCADIA.] Its area is calculated by Mr. Clinton at 1162 square miles (*Fasti Hell.*, ii., p. 385), which is about the area of Staffordshire.

Messenia is described by Pausanias as the most fertile province in Peloponnesus (*iv.* 15, § 3); and Euripides, in a passage quoted by Strabo (*viii.*, p. 366), speaks of it as a land well watered, very fertile, with beautiful pastures for cattle, and possessing a climate neither too cold in winter nor too hot in summer. The western part of Messenia is drained by the river Pamisus, which rises in the mountains between Arcadia and Messenia, and flows southward into the Messenian bay (Gulf of Koroni). The basin of the Pamisus is divided into two distinct parts, which are separated from each other on the east by some high land which stretches from Taygetus to the Pamisus, and on the western side of the river by Mount Ithome. The upper part, usually called the plain of Stenyclerus, is of small extent and moderate fertility; but the lower part south of Ithome is an extensive plain, celebrated in antient times for its great fertility, whence it was frequently called *Macaria*, or the 'blessed.' Leake describes it as covered in the present day with plantations of the vine, the fig, and the mulberry, and 'as rich in cultivation as can well be imagined.' (*Travels in the Morea*, i., p. 352.) The western part of Messenia is diversified by hills and valleys, but contains no high mountains.

Messenia, called in Homer *Messene*, is said by Pausanias to have derived its name from Messene, the wife of Polycaon, the first king of the country, who is described as the younger son of Lelex, king of Laconica (*iv.* 1, § 1, 2). After the lapse of five generations, the sovereignty is said to have passed into the hands of Perieres, the son of *Æolus*. At the time of the Trojan war *Messenia* appears to have been subject to Menelaus, with the exception of Pylus and probably part of the western coast, which was under the dominion of Nestor. After the death of Menelaus, the Neleid princes of Pylus are said by Strabo (*viii.*, p. 359) to have obtained the whole of the country. On the division of the Peloponnesus, after the Dorian conquest under the Heraclidæ, *Messenia* fell to the share of Cresphontes, who fixed his capital in Stenyclerus, and divided the country into five districts. (Strabo, p. 361.) Pylus however appears to have retained its independence till a much later time.

In the middle of the eighth century before the Christian æra, a series of disputes and skirmishes arose on the borders of *Messenia* and *Laconica*, which gave rise to a confirmed hatred between the two nations. Prompted by this feeling, the Spartans are said to have bound themselves by an oath never to return home till *Messenia* was subdued; and they commenced the contest by a midnight attack on *Amphieia*, a frontier town, which they took, and put the inhabitants to the sword. This was the commencement of what is called the first *Messenian* war, the date of which is usually given, though it cannot be fixed with certainty, as B.C. 743. After a contest of twenty years, during which the *Messenian* king Aristodemus distinguished himself by deeds of heroic valour, the *Messenians* were subdued and reduced to the condition of the *Laconian* helots. After bearing the yoke for thirty-nine years, the *Messenians* took up arms against their oppressors, B.C. 685, under the conduct of Aristomenes, a noble youth of the royal blood. [ARISTOMENES.] The *Messenians* however were again subdued, B.C. 668; and those who remained in their native country were treated with the greatest rigour. The majority of freemen however withdrew from *Messenia*, and a considerable number, under the two sons of Aristomenes, sailed to Italy, and settled at Rhegium. They afterwards obtained possession of Zancle, on the opposite coast of Sicily, and called it

Messene, which has retained the same name (*Messina*) to the present day.

The Messenians again revolted in B.C. 464. This war, usually called the third Messenian war, lasted ten years; at the end of which time, the Messenians, who had occupied the strongly fortified mountain of Ithome, surrendered on condition of being allowed to retire from the Peloponnesus. The Athenians, who were not at that time on good terms with Sparta, gladly allowed them to settle at Naupactus, a town at the entrance of the Corinthian gulf, which they had lately taken from the Locri Ozolæ. (Thucyd., i., 101, 103; Paus., iv., 24, § 2; Diod., xi. 70.) This place however the Messenians were obliged to quit, when, at the end of the Peloponnesian war, the Spartans became masters of Greece; but after the supremacy of Sparta had been overthrown by the battle of Leuctra, Epaminondas formed the design of restoring the independence of Messenia, and accordingly sent messengers to Italy, Sicily, and all parts of Greece, to invite the long-exiled Messenians to return to their native country. Numbers obeyed the summons, and in B.C. 369 a town was built at the foot of Ithome, which they called Messene. The independence of the Messenians was guaranteed by the peace concluded B.C. 361; and Messenia continued to remain an independent state till the dissolution of the Achæan confederacy. In the Messenian state, as restored by Epaminondas, the antient national manners are said to have been retained; and the dialect remained, up to the time of Pausanias, the purest Doric that was spoken in the Peloponnesus (iv. 27, § 5; Müller's *Dorians*, ii., p. 421, Engl. Transl.).

The chief towns on the western coast were Pylos and Methone, or Methone. The bay of Pylos (*Navarino*), which is protected from the swell of the sea by the island of Sphacteria (*Sphagia*), is the best harbour in the Peloponnesus. Pylos was situated at the foot of Mount Ægæus, according to Strabo, and must not be confounded with the fortress which was erected by the Athenians in the Peloponnesian war at the northern entrance of the bay, on the spot called Coryphasium by the Lacedæmonians. (Thucyd., iv. 103, 104.) Methone, or Methone (*Modon*), is said by Pausanias (iv. 35, § 1) to have been antiently called Pedasus, a town mentioned by Homer: it appears to have been a place of some importance in the time of Pausanias. Passing the promontory Acritas (*Cape Gallo*), we enter upon the Messenian Gulf, at present called Koroni: forty stadia north of Acritas was Asine (Paus., iv. 34, § 7), originally inhabited by the Dryopes: following the coast, we come to Colonides, forty stadia north of Asine; and afterwards to Æpea, which was called Corone after the restoration of the Messenians. At the head of the gulf, and east of the river Nedon, was Phæræ, or Pharæ, which was annexed to Laconia by Augustus (Paus., iv. 30, § 2); and on the eastern coast of the gulf were Abia, which is mentioned by Homer, according to Pausanias (iv. 30, § 1), under the name of Ira, and Leuctrum or Leuctra, which belonged at one time to Laconia. (Strabo, p. 361; compare Tac., *Ann.*, iv. 43.) It is difficult to determine the boundaries of Laconia and Messenia, as they differed at various times. Müller makes the river Nedon, near Pharæ, the antient frontier line (*Dorians*, ii., p. 460); but in the time of Pausanias, the boundary was a woody hollow called Chærius, twenty stadia south of Abia (iv. 30, § 1). Strabo blames Euripides for making the river Panisus the boundary (p. 366); but perhaps Euripides referred to a small river of the same name, which Strabo himself tells us was in the vicinity of Leuctrum (p. 361).

The only town inland of any importance was Messene, situated, as already mentioned, at the foot of Mount Ithome, on the summit of which was the citadel. Strabo speaks of this citadel and of Acrocorinthus as the two strongest places in Peloponnesus (p. 361); and the account of Pausanias, who praises the strong fortifications of the town, is confirmed by the solid and beautiful masonry which remains to the present day.

MESSIAH (מָשִׁיחַ) is a Hebrew word, of the same signification as the Greek *Χριστός* (*Christ*) *anointed*. In the Old Testament the word is repeatedly applied to persons who were consecrated to the service of God in some sacred office. Thus the Jewish priests, prophets, and kings are called *anointed* (Messiah), or *the anointed of God*. From this general meaning the word has passed into a particular use, referring to the illustrious personage whom the antient Jews expected, and whom their descendants still expect,

to confer some signal blessings on their nation and the world. The word is found in this sense twice in the Old Testament, in *Psalms* ii. 2, and in *Daniel*, ix. 25, 26.

The expectation of the Messiah, first excited by the promise given to Eve after the fall of man (*Genesis*, iii. 15), may be traced from the exclamation of Eve at the birth of Cain, 'I have gotten a man from Jehovah,' or 'a man from Jehovah' (*Gen.*, iv. 1), down through the patriarchal history, the Mosaic law, and the whole series of the Jewish prophets; and it is very generally admitted that remnants of the early belief upon this subject are plainly seen in the religion and traditions of nearly all heathen nations. For information on these traditions, see Dr. J. P. Smith's *Scripture Testimony to the Messiah*, book ii., c. 2; and Bp. Horsley's *Dissertation on the Prophecies of the Messiah, dispersed among the Heathen*.

The belief of the antient Jews respecting the person and office of the Messiah is of course derived from the passages of the Old Testament which are understood as predictions concerning him. An elaborate examination of all such passages occupies the 4th chapter of the 2nd book of Dr. Smith's *Scripture Testimony to the Messiah*, and the following is his summary of the results of the inquiry (*Ibid.*, ch. v.) 'From these sources we have learned, that the Messiah was to be a real and proper human being (*Gen.*, iii. 15; xxii. 18, &c.); the descendant of Adam, Abraham, and David (*Gen.*, xxii. 18; 2 *Sam.*, vii., 19, &c.); in some peculiar sense the offspring of the woman (*Gen.*, iii. 15); the perfectly faithful and devoted servant of God (*Is.*, xlii., 1; lii., 13); the messenger, supreme in rank above all others, of divine authority and grace (*Is.*, xlviii., 16); a heavenly teacher, inspired with the fulness of divine gifts and qualifications (*Is.*, xi., 2); the great and universal lawgiver, who should be the author and promulgator of a new, holy, and happy government over the moral principles, characters, and actions of men (*Deut.*, xviii., 18, 19; *Is.*, ix., 7); a high priest, after a new and most exalted model (*Ps.*, cx., 4); the adviser of the wisest counsels (*Is.*, ix., 6); the pacificator and reconciler of rebellious man to God, and of men among themselves (*Ibid.*); the kind and powerful Saviour from all moral and natural evil (2 *Sam.*, xxiii., 1-7; *Job*, xix., 23-27; *Is.*, xl., 10; xlv., 21). The divine oracles have also informed us that, in the execution of these benevolent purposes, he should undergo the severest sufferings from the malice of the original tempter, from the ingratitude and disobedience of men, and from the especial circumstance of his devoting himself a voluntary sacrifice to procure the highest benefits to those of mankind who should concur in his plan of mercy and holiness (*Gen.*, iii., 15; *Psalms*, xxii., lxix.; *Is.*, lii., liii.; *Zech.*, xii., 10). They have assured us that, from his deep distresses, he should emerge to glory, victory, and triumph; that he should possess power, authority, and dominion, terrible to his determined adversaries, but full of blessing and happiness to his obedient followers; that he should gradually extend those benefits to all nations; and that his beneficent reign should be holy and spiritual in its nature, and in its duration everlasting (*Gen.*, xlix., 10; 2 *Sam.*, xxiii., 1-7; *Ps.*, ii., xlv., lxxii., cx.; *Is.*, xl., 5; *Dan.*, vii., 13, 14). The testimony of heaven likewise describes him as entitled to the appellation of *Wonderful* (*Is.*, ix., 5); since he should be, in a sense peculiar to himself, the Son of God (*Ps.*, ii., 7; *Is.*, ix., 6); as existing and acting during the patriarchal and the Jewish ages, and even from eternity (*Ps.*, xl., 7-9; *Mic.*, v., 2, and the passages which relate to the *Angel of Jehovah*); as the all-sufficient guardian and protector of his people (*Is.*, xl., 9-11, &c.); as the proper object of the various affections of piety, of devotional confidence for obtaining the most important blessings, and of religious homage from angels and men (*Ps.*, ii., 12; xvii., 7; *Is.*, xlv., 21-25). That testimony, finally, declares him to be the eternal and immutable being (*Ps.*, cii., 25-28), the Creator (*Ps.*, cii., 25), God, the Mighty God, Adonai (*Ps.*, xlv., 6; *Is.*, ix., 6; xlv., 21), Elohim (*Is.*, vi., 1; *Mal.*, iii., 1), Jehovah (2 *Sam.*, xxiii., 4; *Is.*, vi., 5; viii., 13; xl., 3, 10; xlv., 21-25; *Zech.*, ii., iii., vi.). See also Hengstenberg's *Christologie des Alten Testaments*.

The expectations of the Messiah among the Jews in the period between the close of the Old Testament and the birth of Christ, as indicated by the Targums, the *Apocrypha*, the *Book of Enoch*, and the writings of Philo and Josephus, were confused and often inconsistent. Respecting the doctrines of the Targums on the *Memra of Jah*, or *Word of God*, and of Philo on the *Logos*, see *Logos*. In

the *Apocrypha* the word Messiah or Christ never once occurs, and there are no passages which can be said with any certainty to refer to the Messiah, unless perhaps one in *Ecclesiasticus*, li. 10, 'I called upon the Lord, the Father of my Lord.' In the *Book of Enoch*, which was written by a Jew about B.C. 30, we have an account of a vision (evidently imitated from *Daniel*, vii. 9-14), in which the 'Son of Man' is associated with the 'Antient of Days,' and is described as a person 'to whom righteousness belongeth,' 'who will reveal all the treasures of that which is hidden,' 'who existed and whose name was called upon in the presence of the Lord of the Spirits before the world was created and for ever,' who 'will be a support to the righteous and holy' and 'the light of the nations,' before whom 'all who dwell upon the earth will fall down and worship,' who is to be a preserver and ruler, and superior to the kings of the earth, whom he will overthrow 'because they have denied the Lord of Spirits and his Messiah.' (Abp. Laurence's *Book of Enoch*, chaps. xlv., xlviii., lxi.) From Josephus we learn nothing on the subject, a fact sufficiently accounted for by his own temporising disposition and the circumstances in which he was placed.

At the time of Christ's advent various expectations respecting the Messiah prevailed among the Jews. It is sufficiently evident from the New Testament, that, while some looked for a human prince who was deliver them from the Roman yoke and exalt them to national supremacy, others expected a divine teacher who was to confer spiritual blessings not only upon them but also on the Gentiles. (Bertholdt's *Christologia Judæorum Jesu Apostolorumque Aetate*, and Kuinoel's *Comment. in Lib. Hist. N. T., Proleg. ad Johan.*, § 7.) The opinion of the Samaritans, recorded in *John*, iv. 42, that the Messiah would be a religious teacher and 'the Saviour of the world,' is worthy of special attention, because the Samaritans received no part of the Scriptures but the Pentateuch, and were cut off from all intercourse with the Jews by national hatred. (Bishop Horsley's *Sermons*, xxiv.-xxvi.)

It is the belief of all Christians that Jesus Christ is the Messiah predicted in the Old Testament. The evidence of this fact is contained in the New Testament, especially in the four gospels, from which it appears that his lineal descent, the place, time, and other circumstances of his birth, the constitution of his person, the history of his life and death, the miracles he performed, and the doctrines he taught, all agree to the minutest particular with the prophecies respecting the Messiah. (Fuller's *Jesus the true Messiah*.)

The Jews, having rejected the claims of Jesus Christ, are still looking for the Messiah, whom they almost universally expect to be a mere man and to confer on them only temporal blessings. Most of the Rabbinical writers of the middle ages speak of two Messiahs: one, the son of David, the conquering monarch; the other, the suffering Messiah, the son of Joseph, who is to fall in battle, fighting for his countrymen against Gog and Magog, and in this sense to die for them. This opinion may be traced up to the sixth century, and perhaps higher. In these Rabbinical writings, especially in the book *Zohar*, there are scattered valuable fragments of the more antient belief of the Jewish people on this subject. (Schöttgenii, *Horæ Hebraicæ et Talmudicæ*; and Lightfoot's *Works*.)

In different ages there have appeared numerous 'false Messiahs' (*Matt.*, xxiv. 24). Of these ecclesiastical historians reckon twenty-four, for an account of whom the reader is referred to Johannes à Lent's *History of False Messiahs*.

MESSINA, INTENDENZA, or Province of, comprehends the north-east extremity of Sicily, and is bounded on the west by the province of Palermo, on the south by that of Catania, on the north by the Mediterranean, and on the east by the Faro or Straits of Messina, which divide it from Calabria. The greatest length of the province is 60 miles, and its breadth 30 miles. A continuation of the mountainous ridge which runs across Sicily from west to east, known to the antients under the various names of Nebrodes, Heræi, Pelorias, &c., covers the greater part of the interior of the province, and terminates at Cape Pelorum. A number of torrents, called 'flumare,' during the rainy season descend from both sides of the ridge, but they are nearly dry in summer. On the south-west the province of Messina skirts the base of Ætna, the mass of which belongs to the province of Catania. The province of Messina has no

great plains, but it contains many valleys. Its chief products are wine, oil, and fruit of every sort. The towns of the province are—1, Messina. 2, Melazzo, the antient Mylæ, a seaport town on a promontory of the northern coast facing the Lipari islands, fifteen miles west of Messina, with a castle and 7000 inhabitants, many of whom are employed as sailors and fishermen. It exports much wine from the neighbouring districts, and also oil. The red Faro wine, which is made nearer to Messina, is better than that of the district of Melazzo. 3, Patti, on the same coast, fifteen miles south-west of Melazzo, and not far from the ruins of the antient Tyndaris, has several churches and convents, and between 4000 and 5000 inhabitants. 4, Taormina, the antient Tauromenium, on the east coast of the island, and at the north-east base of the group of Ætna, an old looking town with about 4000 inhabitants, is built upon a steep cliff towering above the sea; it has an antient theatre and other ruins scattered around. 5, Castro Reule, in a valley rich in oil and wine, has 12,000 inhabitants. 6, Randazzo, at the north base of Ætna, in a very fertile district, has 15,000 inhabitants.

The islands of Lipari are included in the administrative province of Messina. [LIPARI ISLANDS.]

MESSINA, the Town of, lies on the north-east coast of Sicily opposite the Calabrian coast, from which it is separated by the channel of the Faro, which is here about four miles wide, but becomes much narrower farther north opposite Faro Point, or Cape Pelorum. The town of Messina is built partly on the slope of a steep hill, and partly along the sea-shore at the foot of it. The port of Messina is formed by a strip of sandy beach projecting into the sea at the south side of the city and sweeping round in the form of a semicircle. From the sickle-like form of this strip of land, the town received from its first Greek inhabitants the name of Zankle ('curved' or 'bent'),* which was afterwards changed into that of Messene. (Thucyd. vi. 5.) On this narrow tract of land are the citadel, the lazaretto, the lighthouse, and the castle of Salvatore at the entrance of the harbour, which faces the north. The harbour, which is more than two miles in circumference, is one of the best in the Mediterranean. The larger part of the town rises in the form of a crescent on the west side of the harbour, along which is a handsome quay lined on one side by a row of fine buildings called La Palazzata: this quay constitutes the fashionable promenade of the town.

The view over the channel, the opposite coast of Calabria with its towns and villages, and the lofty Apennines behind them, and on the other side the low promontory of Faro, with its tower advancing into the sea as if to meet the Italian coast, form a splendid landscape, which is one of the finest even in the Mediterranean, a sea whose shores are remarkable for a variety of beautiful scenery. The climate of Messina, though hot in summer, is very healthy, and is not so sultry as that of Palermo or Catania.

Messina has many remarkable buildings; the cathedral, the church of La Candelara, and that of the Capuchins, contain some fine paintings. The church of Santa Maria de Graffeo belongs to the Greek clergy, whose protopapa is the spiritual head of the Greek or Epirote colonies settled in Sicily. The royal palace, the archiepiscopal palace, that of the senate, the seminary, the great hospital, the arsenal, the loggia or exchange, the granaries, the royal college, the bank, and the two theatres, are all worthy of notice. The public library, founded by Constantine Lascaris, is rich in Greek MSS. Messina is an archbishop's see, has a court of appeal for the province, a commercial tribunal, a royal college, called Accademia Carolina, for the study of law and medicine, and about 60,000 inhabitants. (Serristori, *Saggio Statistico*; *Nuova Guida dei Viaggiatori in Italia*, Milan, 1830.)

Coin of Zankle (Messina). British Museum.

Messina is the most trading town of Sicily; it exports oil, currants and raisins, wine, almonds, lemons, sumach,

* The name was also written 'Dankle,' as appears by the coins which accompany this article.

lamb-skins and kid-skins, liquorice, and other produce of the island. The spinning and weaving of silk form the principal manufacture, and employ several thousand hands.

(*Saggio su i mezzi di moltiplicare le Ricchezze della Sicilia*, by G. de Welz, 4to., Paris, 1822.)

For the history of Messina see **HIERON II.**, and **SICILY**.

METACENTRE is a point in a floating body, the position of which, relative to that of the centre of gravity, determines the conditions for the stability or instability of the equilibrium of that body. The equilibrium is *stable*, if, when the body receives a slight disturbance from its position, it tends, by the combined action of its own weight and the pressure of the fluid in which it is partially immersed, to re-adjust itself in that position after some oscillations; and the equilibrium is *instable* if a slight disturbance will cause the body to overset and acquire a different position, which will then necessarily be one of stable equilibrium.

The surface of a heavy fluid at rest is a horizontal plane; the portion of this plane which we may imagine to be within the floating body is called the *plane of floatation*.

When a body floating on a fluid is in equilibrium, the weight of the body applied downwards at its centre of gravity must be equal and exactly opposite to the pressure of the fluid, or, which is the same, to a force equal to the weight of the displaced fluid, applied upwards at the centre of gravity of this portion of the fluid; hence in this position the right line joining these two centres is vertical, and is called the *line of support*.

When the body is slightly disturbed from this position, the plane of floatation evidently alters its position in the floating body; the centre of gravity of the part immersed also changes, and the *thrust* of the fluid will in general no longer pass through the centre of gravity of the whole body. The magnitude of this force will however undergo but a very small change, and the body is now subjected to the action of two forces which are equal and contrary, but no longer directly opposite.

The figure and density of a body may however possibly be such that the thrust of the fluid may, after the disturbance, continue to pass through the centre of gravity of the body. The equilibrium is then said to be *indifferent*, inasmuch as the disturbance communicated only produces a new position of equilibrium. This happens when a body floats in a fluid of equal density with itself, and in other cases, as in a floating sphere. We may observe that if the disturbance of the equilibrium consisted merely of an elevation or depression of the centre of gravity, small vertical oscillations would be the consequence: the disturbance considered here is supposed such as to tend to turn the body *round* its centre of gravity, or to make the original line of support deviate in a vertical plane through a very small angle; this line is called the *axis* passing through the centre of gravity.

When the position of the body is thus disturbed, if the line of thrust when produced upwards meets the above-named axis, the point of intersection is called the *metacentre*. The consequent motion of the body will then be the same as if the centre of gravity were fixed, and the thrust applied vertically at the metacentre; hence if the metacentre be *above* the centre of gravity, the thrust tends to re-adjust the axis, and the equilibrium is *stable*; if *below*, that force tends to carry the axis farther from its original place, and the equilibrium is *instable*: if the two centres coincide, the equilibrium is *indifferent*. We give an example:—

Fig. 1. ABCD is a vertical *square* section passing through G, the centre of gravity of a rectangular beam floating on a fluid of twice its specific gravity, this section being at right angles to the faces of the beam; therefore
P. C., No. 928.

$GH = \frac{1}{2} AB$; and if $gH = \frac{1}{2} AB$, g is the centre of gravity of the fluid displaced, Gg is the line of support, and EF the plane of floatation.

Fig. 2 represents the same body turned round its centre of gravity through a small angle FGF or θ . Let $GF = 1$; we must find g' , the centre of gravity of $efCB$, and draw $g'O$ vertical or perpendicular to ef , cutting the axis GH in O the metacentre. Let m, n , be the centres of gravity of the portions EGe , FGf , and h that of the portion $EGFCB$, then $hg : gm :: \text{solid } EGe : \text{solid } eGFCB$; and $hg' : g'n :: \text{solid } FGf : \text{solid } eGFCB$; but the solids EGe , FGf , are equal: hence $hg : gm :: hg' : g'n$, therefore gg' is parallel to mn , or nearly horizontal, and $= mn \cdot \frac{\text{solid } EGe}{\text{solid } EFCB}$ nearly. Now $mn = 2 Gm = \frac{1}{2}$, and solid $EGe = \frac{1}{2} \theta \times \text{length}$, solid $EFCB = 2 \times \text{length}$; therefore $gg' = \frac{1}{3} \times \frac{1}{4} \times \theta = \frac{\theta}{3}$; but $\angle gOg' = \theta$; therefore $gO = \frac{1}{3}$, or $GO = \frac{GH}{6}$: hence the equilibrium is *instable*. If the equilibrium were *stable*, the times of the oscillations would be found by supposing the thrust applied at O , the point G remaining fixed.

METAGALLIC ACID is prepared by the partial decomposition of gallic acid by quickly heating it up to about 480° . Carbonic acid and water are formed and separated, and a black, shining, tasteless compound is left, which is not dissolved by water, but is easily taken up by the alkalis ammonia, potash, and soda in solution. It also decomposes the solutions of the alkaline carbonates, expelling the carbonic acid. Metagallate of potash gives insoluble precipitates with the salts of barytes and strontia, and also with many metallic salts.

It is composed of—

Three equivalents of hydrogen . . .	3
Twelve equivalents of carbon . . .	72
Three equivalents of oxygen . . .	24

Equivalent 99

METALLURGY is the art of separating metals from their ores. The processes vary for every metal, and are described under each.

METALS. The metals form a numerous and highly important class of simple or elementary bodies. Different opinions are entertained as to their number, which arises from the circumstance that a few substances are regarded as metallic in their nature by some chemists, while by others their claim to this title is either doubted or denied; thus by Berzelius a substance which he discovered and called *selenium* is regarded as a metal, but it is not so ranked by any English chemist; again, the base of silica is by some classed as a metal, and by them termed *silicium*; whereas many consider it as more nearly allied in nature to boron, and call it *silicon*.

We shall consider neither of these bodies as metals. Independently of them, the metals, including those which have been longest known, as well as some whose claims are even yet somewhat doubtful, amount to forty-two; they are, given alphabetically, as follows:—aluminium, antimony, arsenic, barium, bismuth, cadmium, calcium, corium, chromium, cobalt, columbium, copper, glucinium, gold, iridium, iron, lanthanum, lead, lithium, magnesium, manganese, mercury, molybden, nickel, osmium, palladium, platina, potassium, rhodium, silver, sodium, strontium, tellurium,

thorium, tin, titanium, tungsten, uranium, vanadium, yttrium, zinc, zirconium.

The general properties of the metals are, that, with the single exception of mercury, they are all solid at the usual temperature of the air, and the colour of most of them is greyish white. Silver is of a pure white; tin, cadmium, platina, palladium, mercury, iridium, are white, with a slight shade of grey; antimony is white, with a slight bluish tint; cobalt, nickel, iron, manganese, and rhodium are more grey; lead and zinc are of a bluish grey; chromium, molybden, and tungsten are of a pure grey colour; uranium is brown; gold, yellow; copper and tellurium, yellowish-red; and columbium appears to have the same colour.*

The lustre of metals is great and peculiar, and is well known by the name of the *metallic lustre*; they differ however very considerably in the degree in which they possess this property. Professor Leslie arranges them as follows, the first possessing the greatest lustre:—platina, silver, mercury, gold, copper, tin, and lead. When reduced to a state of minute division, as by filing, or by any other means, the metallic lustre is lost, but the colour remains. The metals are generally reckoned perfectly opaque, even when reduced to thin leaves; but it is found that gold-leaf, which is $\frac{1}{100000}$ part of an inch thick, suffers light to pass through it, and it has a green colour; it is therefore extremely probable that all metals, if they could be rendered equally thin, would also be translucent. There are some metals, such as lead, tin, copper, and iron, which, when rubbed, emit a peculiar and disagreeable smell. There are others which yield a peculiar odour when heated and vaporized; this is especially the case with arsenic, and it occurs also with antimony; the greater number of the metals are however inodorous; a few of them possess taste, but it is in all cases disagreeable.

Formerly great density and a specific gravity superior to that of other bodies were considered as among the principal characteristics of metals. But the brilliant discoveries of Sir H. Davy have proved that substances which are even lighter than water, potassium and sodium for example, possess every property which belongs to metals. The density of all the metals has not been ascertained. Beginning with the lightest, their specific gravities are as follows:—potassium 0.865, sodium 0.972, titanium 5.300, columbium 5.610, arsenic 5.884, chromium 5.900, tellurium 6.115, antimony 6.702, manganese 7.05, zinc 7.191, iron 7.770, cobalt 7.834, nickel 8.279, cadmium 8.694, copper 8.958, uranium 9.000, bismuth 9.830, silver 10.474, rhodium 10.649, lead 11.445, palladium 11.860, mercury 13.568, tungsten 17.600, iridium 18.680, gold 19.361, platinum 21.530.

The following metals are ductile or malleable, arranged alphabetically:—

Cadmium	Iron	Osmium?	Silver
Copper	Lead	Palladium	Sodium
Gold	Mercury	Platina	Tin
Iridium?	Nickel	Potassium	Zinc

The following metals are so brittle that the greater number of them may be reduced to powder:—

Antimony	Chromium	Molybden	Tungsten
Arsenic	Cobalt	Rhodium	Uranium
Bismuth	Columbium	Tellurium	
Cerium	Manganese	Titanium	

The degrees of ductility and malleability of those metals which possess those properties are very different, and some metals are so totally devoid of them that they may be broken by the hammer, and even reduced to powder. Ductility is that property by which metals are susceptible of being drawn into wire, and malleability is that by which their form is changed, so that they are beaten into thin leaves under the hammer or extended by pressure. The annexed tables show that the metals mentioned in them do not follow in the same order as to those properties.

Order of Ductility.	Order of Malleability.
Gold	Gold
Silver	Silver
Platina	Copper
Iron	Tin
Copper	Platina
Zinc	Lead
Tin	Zinc
Lead	Iron

*This statement of colours is taken from Berthier, 'Traité des Essais par la Voie sèche,' tome i., p. 527. It will perhaps appear on examination that scarcely any two authors agree precisely as to the colours of metals.

The ductility and malleability of metals are in general considerably increased by heat, but only to a certain extent. There are some metals which are malleable only between two very near degrees of temperature: such, for example, is the case with zinc.

The degree of tenacity of metals is indicated by the powers of their wires in supporting a given weight. The following weights are capable of being sustained by wires of the annexed metals about 0.840 of a line in diameter:—

	lbs.	dec. avoird.	pts.
Iron	•	•	549.250
Copper	•	•	302.278
Platina	•	•	274.320
Silver	•	•	187.137
Gold	•	•	150.753
Zinc	•	•	109.540
Tin	•	•	34.630
Lead	•	•	27.621

There are only few metals which are very hard when they are pure. The following table exhibits some of them arranged according to the degree in which they possess this property, according to Professor Brande:—

Titanium	Silver
Rhodium	Bismuth
Tungsten	Gold
Palladium	Zinc
Manganese	Antimony
Iron	Cobalt
Nickel	Tin
Platina	Arsenic
Copper	Lead

M. Dumas however arranges the metals somewhat differently: he begins with manganese as the hardest, which certainly is not the case; for titanium, which he does not mention at all, should precede that and every other metal. M. Dumas's statement is as follows:—

Manganese	Harder than tempered steel.
Chromium	} Not scratched by glass.
Rhodium	
Nickel	} Scratched by glass.
Cobalt	
Iron	
Antimony	
Zinc	
Palladium	} Scratched by carbonate of lime.
Platina	
Copper	
Gold	
Silver	
Tellurium	} Scratched by the nail.
Bismuth	
Cadmium	} Soft as wax.
Tin	
Lead	} Liquid.
Potassium	
Sodium	
Mercury	

The elasticity and sonorousness of metals are generally associated with their degree of hardness. There are not however any metals which are by themselves either very elastic or sonorous; but there are alloys which possess these properties in a high degree, as for example those of copper and tin.

The structure of metals is sometimes lamellar, sometimes granular, and frequently crystalline: indeed, some of them, and more especially copper, occur crystallized in the form of the cube and its varieties. Bismuth is a metal which may be artificially crystallized in cubes with great facility.

As to the action of the imponderable bodies upon the metals, it must be premised that no particular effect has been attributed to the agency of light.

The metals are good conductors of heat; they differ however greatly in the celerity with which it pervades them. According to M. Despretz, assuming the conducting power of gold as a standard, that of the undermentioned metals is as follows:

Gold	10,000	Iron	3,743
Silver	9,730	Zinc	3,638
Platina	9,810	Tin	3,039
Copper	8,932	Lead	1,796

Capacity for Heat.—MM. Petit and Dulong have deter-

mined with great care the calorific capacity of a great number of metals for 1° of the centigrade thermometer, that of water being taken as unity. Their results are:

Bismuth	0.0288	Zinc	0.0927
Lead	0.0293	Tellurium	0.0912
Gold	0.0298	Copper	0.0949
Platina	0.0314	Iron	0.1000
Mercury	0.0330	Nickel	0.1038
Tin	0.0515	Cobalt	0.1498
Silver	0.0557		

MM. Petit and Dulong deduce from their experiments the important conclusions that the atoms of all substances have the same capacity for heat, or at least that this capacity bears a very simple relation to the weights of the atoms.

Dilatibility.—Immediately that heat pervades the metals, and before it fuses them, it expands them in all directions. This dilatation is different in each metal; it varies also in the same metal with every degree of the thermometric scale; but from the freezing to the boiling point of water it may however be regarded as nearly constant; between these points the linear dilatation for the following metals is such as stated by the authorities named:—

	Laplace and Lavoisier.	Dalton and Davy.
Zinc	..	0.00296
Lead	0.00285	..
Tin	0.00217	0.00278
Silver	0.00191	0.00238
Copper	0.00172	0.00170
Gold	0.00147	0.00194
Steel (tempered)	..	0.00112
Steel (not tempered)	0.00108	..
Platina	0.00086	0.00087
Mercury	..	0.00835

Fusibility.—The fusing point of metals varies extremely, as will appear from the following table copied from Turner's 'Chemistry':—

		Fahr.	Authority.
Fusible below a red heat.	Mercury	−39°	{ Different Chemists.
	Potassium	136	{ Gay Lussac & Thenard.
	Sodium	190	
	Tin	442	{ Crichton.
	Bismuth	497	
	Lead	612	
	Tellurium, rather less fusible than lead		Klaproth.
	Arsenic, undetermined		
	Zinc	773	Daniell.
	Antimony, a little below red heat		
	Cadmium	about 442	Stromeyer.
	Silver	1873	Daniell.
	Copper	1996	Daniell.
	Gold	2016	Daniell.
	Cobalt, rather less fusible than iron		
Infusible below a red heat.	Iron, cast	2786	Daniell.
	Iron, malleable	{ Require the highest heat of a smith's forge.	
	Manganese		
	Nickel, nearly the same as cobalt		
	Palladium		
	Molybden	{ Almost infusible, and not to be procured in buttons by the heat of a smith's forge.	
	Uranium		
	Tungsten		
	Chromium		
	Titanium	{ Infusible in the heat of a smith's forge.	
	Cerium		
	Osmium		
	Iridium		
	Rhodium		
	Platina		
	Columbium		

Volatility.—Metals also differ in this respect. Some metals are volatilized at moderate degrees of heat; among these are mercury, cadmium, arsenic, tellurium, zinc, potassium, and sodium; but there are others which may be exposed to the most intense heat of a wind furnace without being at all vaporized.

Electricity.—Becquerel has given the following table of the relative conducting powers of the metals for electricity, the wires of the several metals being of equal diameter:—

Copper	100	Iron	15.80
Gold	93.60	Tin	15.50
Silver	73.60	Lead	8.30
Zinc	28.50	Mercury	3.45
Platina	16.40	Potassium	1.33

According to Pouillet, each of the following metals is positive with relation to that which follows it:—zinc, lead, tin, iron, antimony, bismuth, copper, mercury, silver, gold, tellurium, palladium, platina.

Magnetism.—There are two metals only which are capable of being rendered permanently magnetic, namely, iron and nickel; the former of these only is met with possessing this property in nature; it is an oxide of iron, and commonly called the *loadstone*. Most of the metals combine with each other and form compounds differing very materially in properties from their constituent metals. [ALLOYS.]

Oxygen and Metals.—All metals unite with oxygen, but with different degrees of facility and affinity; most of them combine with more than one proportion of oxygen and some of them with several proportions. The nature of the compounds formed is extremely various; thus some metals form with oxygen comparatively inert compounds or mere oxides, such are iron and zinc; others, such as potassium and sodium, when oxidized become alkalis; while arsenic and chromium form acids with this element. It has been already observed that some metals unite with several proportions of oxygen, and these may be mere oxides, as in the case of iron; or oxides and acids, as occurs with manganese; but there is no case of any metal forming a mere oxide and an alkali with different proportions of oxygen, or an acid and an alkali under the same circumstances.

Azote and Metals.—No permanent compound of these is known.

Hydrogen and Metals do not readily combine; there are only two remarkable compounds; these result from the union of hydrogen with arsenic and with tellurium.

Chlorine and Metals combine with great facility, and the compounds are extremely important; every metal is indeed susceptible of this combination; chlorine possesses the remarkable property of forming in general volatile compounds with the metals.

Bromine, sulphur, iodine, and phosphorus combine with most of the metals: for an account of their properties, as well as those which the metals form with the preceding elements, see each particular metal. The action of the air, of water, and the acids, upon the metals, is extremely various, and depends greatly upon their respective affinity for oxygen; few of them are oxidized in dry air, but many of them tarnish and some oxidize readily in it when moist, of which iron is an example. Some metals, as potassium, sodium, and manganese, decompose water even at common temperatures, combining with its oxygen and evolving the hydrogen; others, as iron and zinc, require to be strongly heated, or the presence of an acid, to effect this decomposition.

Although most metals are dissolved by acids, yet platina and gold are exceptions to it, these and some others requiring chlorine, and generally in the nascent state called *aqua regia*. Few metals however are acted upon by acids without the presence of water, and in some instances the water, in others the acid, and often both, suffer decomposition, and it is to be observed that no metal dissolves in acid unless it be either previously oxidized or acquire oxygen from the mixture of acid or water in which the solution takes place: the salts formed are in many cases of the highest importance in chemical investigations, in the chemical arts, and in medicine.

METAMORPHOSIS OF ORGANS, in the Vegetable Kingdom, consists in an adaptation of one and the same organ to several different purposes; connected with which are changes in form, size, colour, and other particulars.

The plan upon which the development of plants takes place, notwithstanding the infinite variety observable in the vegetable kingdom, is extremely simple, and is executed by

modifications of one kind of elementary tissue, and one kind of external organ. In the beginning, that is to say, in its embryo state, a plant is only a mass of spheroidal cellular tissue possessing vitality. But as soon as it is excited into growth, some of the cells lengthen and become woody tissue; others lengthen and generate an elastic spiral thread in their inside, acquiring the form and property of spiral vessels, while numerous other changes of a similar nature are produced; to each of which variations peculiar properties are inherent, such as the conveyance of fluids in particular directions, the conveyance of air, the strengthening of certain parts, the defence of others, and so on. In like manner a plant in the beginning consists of nothing but an axis of growth composed of fibro-vascular tissue enclosed in cellular tissue; to give it lungs and a stomach, without which it could not live, points upon its surface are expanded into leaves; these organs at particular parts of the system alter their texture, colour, and form, and become floral envelopes, or they contract, and organise in their interior a substance called pollen, when they become male organs, or finally, they roll up, and convert themselves into hollow bodies, within which are generated ovules or young seeds. These circumstances rightly understood, are found to afford the clearest explanation of the plan upon which the most complicated modes of vegetable organisation are produced, and especially of those anomalous or monstrous cases whose occurrence is so common and difficult of explanation in the absence of the light thrown upon them by Morphology, or the theory of vegetable metamorphosis.

This subject originated in the second volume of the tenth edition of the *Systema Naturæ*, published in 1759, in which Linnæus thus expresses himself:—‘Leaves are the creation of the *present* year, bracts of the *second*, calyx of the *third*, petals of the *fourth*, stamens of the *fifth*, and the stamens are succeeded by the pistil. This is apparent from *Ornithogalums*, luxuriant and proliforous plants, double flowers, and *Cardui*.’

In December, 1760, these propositions were sustained by Linnæus in a thesis called the ‘*Prolepsis Plantarum*.’ He commences by remarking that ‘as soon as leaves have expanded themselves in spring, a bud is observable in the axil of each. This bud swells as the year advances, and in time becomes manifestly composed of little scales: in the autumn the leaves fall off, but the bud remains, and in the succeeding spring swells, disengages itself from its envelopes, and becomes lengthened: when its outer scales have dried up and fallen off, the inner ones are expanded into leaves, which are separated by a gradual extension of the young branch, and presently each new leaf is found to contain in its bosom a little scaly bud, which in the following season will also be developed as a branch, with other leaves and other buds. Now, when we see a tree adorned with leaves, and in the bosom of these leaves provided with its little buds, we naturally inquire—of what do these buds consist? Can it be of rudimentary leaves, each with its budlets, the latter of other leaves and buds, and so on to infinity, or at least as far as the extension of the plant is likely to proceed? Nature organises living beings out of such minute particles, and even from fluids themselves, that the best eye may in vain seek to penetrate far into her mysteries. I shall however endeavour to show that the composition of buds does not extend further at one time than provision for six years; just as, among animals, we find the little *Volvox globator* containing within the mother its children, grandchildren, great-grand-children, and great-great-grand-children down to the sixth generation.’

The defects of this theory consisted, firstly, in its not accounting for the modifications of the pistil; and, secondly, in the fanciful supposition that the organs of fructification are prepared six years beforehand, and that their peculiar appearance is owing to the time of this development being anticipated by some unknown but ever-acting cause. It was this which probably caused the whole theory to be generally neglected. It was however maintained by Ludwig and Wolff; the latter of whom in particular improved so much upon the speculation of Linnæus, by rejecting what was fanciful and supplying to a certain extent an explanation of the origin of the pistil, that his paper in the *Novi Commentarii Academiæ Petropolitanae* for 1768 would undoubtedly have deserved to be considered the beginning of a new æra in botanical philosophy if it had been known to botanists. But as it was introduced into a paper upon the formation of the intestines of animals, it does not appear

ever to have attracted attention until it was discovered by Miquel a few years ago.

It is in reality to the celebrated poet Göthe that the honour justly belongs of having brought before the world in a clear and philosophical manner the doctrine of all the parts of a plant being reducible to the axis and its appendages, and consequently of having proved, to use his own words, that vegetables ‘develop themselves out of themselves progressively.’ By this means he led to the discovery of the real laws of structure, and of the analogies which exist between one thing and another in different tribes of plants; thus laying the foundation of vegetable comparative anatomy by ‘establishing a principle in harmony with all the laws obeyed by millions of isolated facts.’

A perfect plant consists of branches successively produced out of each other from one common stock, and each furnished with exactly the same organs or appendages as its predecessor. When the fructification is produced, an alteration takes place in the extremity of the fructifying branch, which is incapable, generally speaking, of further prolongation; but as the branches, before they bore fruit, were repetitions the one of the other, so are the branches bearing fruit also repetitions of each other. If a thousand sterile or a thousand fertile branches from the same tree are compared together, they will be found to be formed upon the same uniform plan, and to accord in every essential particular. Each branch is also, under favourable circumstances, capable of itself becoming a separate individual, as is found by cuttings, budding, grafting, and other horticultural processes. This being the case, it follows that what is proved of one branch is true of all other branches.

It is also known that the elementary organs used by nature in the construction of vegetables are essentially the same; that the plan upon which these organs are combined, however various their modifications, is also uniform; that the fluids all move, the secretions all take place, the functions are all regulated upon one simple plan; in short, that all the variations we see in the vegetable world are governed by a few simple laws, which, however obscurely they may be understood by us, evidently take effect with the most perfect uniformity.

Hence it is not only true that what can be demonstrated of one branch is true of all other branches of a particular individual, but also that whatever can be shown to be the principles that govern the structure of one individual, will also be true of all other individuals. It is particularly requisite that this should be clearly understood in order that a just estimate may be formed of the nature of the proofs to be adduced with respect to the doctrines of morphology. Whatever can be demonstrated to be true with regard to one single individual is true of all other individuals: whatever is proved with reference to one organ is proved by implication as to the same organ in all other individuals whatsoever.

Moreover, the fact of one organ being readily transformed into another organ is in itself a strong presumption of the identity of their origin and nature; for it does not happen that one part assumes the appearance and functions of another, if they are originally different. Thus, while the functions of the hand may be performed by the feet, as we know they occasionally are in animals, nothing leads the heart to perform the function or assume the appearance of the liver, or the liver of any other organ. This is one of the arguments of Linnæus.

The first of the organs which are formed by a modification of leaves are the bracts; these bodies are intermediate between the leaves and the calyx. Their nature is extremely various; sometimes they have a greater resemblance to the leaves, and sometimes to the calyx. In some roses, as *R. canina*, they are obviously dilated petioles, to which a leaflet now and then is attached; in other species, as *R. spinosissima*, they differ in no respect from the other leaves. In the tulip a bract is occasionally present upon the scape, a little below the flower; this is always of a nature partaking both of the leaf and the flower. In *Abies excelsa* the purple scale-like bracts often become gradually narrower, and acquire a green colour like leaves. It has been stated by some botanists, that bracts are distinguishable from leaves by not producing buds in their axils; but the inaccuracy of such a distinction is apparent from a variety of cases. In *Polygonum viviparum*, and all viviparous plants, the flowers themselves are converted into buds within the

bracts. There is a bud in the axil of every bract of the rose. The common daisy often bears buds in the axils of the bracts of its involucre; in which state it is commonly known in gardens by the name of 'hen and chickens.' In the permanent monster called *Muscari monstrosum* a small cluster of branches covered with minute imbricated coloured leaves resembling bracts is produced in lieu of each flower. Here all the parts of the fructification, instead of remaining at rest to perform their functions, are attempting, but in vain, to become organs of vegetation; or, in other words, to assume that state from which, for the purpose of perpetuating the species, they had been metamorphosed by nature. Hence it is clear that bracts cannot be essentially distinguished from leaves.

With the calyx begins the flower properly so named; it forms what some morphologists call the outer whorl of the fructification, and with it commences a new order of leaves, namely, those of the fructification, said to be distinguished from the leaves of vegetation by their constantly verticillate arrangement, and by the want of buds in their axils. With the leaves of the fructification all power of further increase ceases: the energies of the plant being diverted from increasing the individual to multiplying the species. The general resemblance of the calyx to the ordinary leaves of vegetation is well known: its green colour, and tendency to develop itself into as many leaves as it consists of divisions, especially in double roses, is so notorious that it need not be insisted on. In the case of *Mesembryanthemum barbatum*, noticed by Linnæus, there is no difference whatsoever between the leaves of the calyx and those of the stem. The resemblance however between the calyx and the stem-leaves is often not apparent; but the identity of the calyx and bracts is usually more obvious. In *Cereus* the transition from the one to the other is so gradual that no one can say where the distinction lies; and in numberless *Ericas* the resemblance of the bracts and calyx is perfect. The divisions of the calyx are also occasionally gemmiferous. A case is mentioned by Röper, in which one of the sepals of *Caltha palustris* was separated from the rest, and furnished with a bud. And Du Petit Thouars speaks of a specimen of *Brassica napus* on which branches were produced within the calyx. A monster of *Herreria parviflora* has been seen of the same nature. (Lindley, *Introduction to Botany*, ed. 2, p. 533.) From this it is apparent that the divisions of the calyx are not only not distinguishable from bracts, but that there is often a strong tendency in the former to assume the ordinary appearance of leaves. There is however another point to which it is necessary to advert, in order to complete the proof of the identity of calyx and leaves; this is, the verticillate arrangement of the former. Leaves are either opposite, alternate, or whorled; and these differences depend wholly upon their greater or less degree of approximation. If the leaves of a plant are rightly considered, they will be found to be inserted spirally round a common axis; that is to say, a line drawn from the base of the lower leaf to that of the one above it, thence continued to the next, and so on, would have a spiral direction. When leaves become approximated by pairs, the spire is interrupted, and the leaves are opposite; let the interruption be a little greater, and the leaves become ternate; and if the interruption be very considerable, what is called a whorl is produced, in which several leaves are placed opposite to each other round a common axis, as in *Galium*. Now a whorl of this nature is exactly of the nature of a calyx, only it surrounds the axis of the plant, instead of terminating it. As we know that such approximations often take place in the stem in the direct line of growth, where the propulsion of the matter of vegetation exists in its greatest activity, there is no difficulty in comprehending the possibility of such an approximation constantly existing at the end of the system of growth, where the propulsion of the matter of vegetation ceases. But the calyx and more inner whorls of the fructification do not always retain their verticillate position; on the contrary, they occasionally separate from each other and assume the same position with regard to the axis of vegetation as is naturally proper to the leaves. This is particularly striking in a very common permanent monster of *Lilium album*, known in the gardens by the name of the double white lily. In this plant the whole verticillation of the parts of fructification is destroyed; the axis is not stopped by a pistil, but is elongated into a stem, around which the white leaves of the calyx are alternately imbricated;

and in double tulips the outer whorl, representing the calyx, frequently loses its verticillate arrangement, and becomes imbricated like the leaves of a stem. The same structure also occurs in the double white *Fritillaria meleagris*. Hence it cannot be doubted that the calyx consists of leaves in a particular state.

The corolla forms the second line or whorl of the fructification. It consists of several divisions, usually not green, and always alternate with those of the calyx. It is a series of leaves arising within those of the calyx, from which it is sometimes indeed very easy to distinguish it; but from which it is so often impossible to discriminate it, that the difference between the calyx and corolla has been one of the most debatable subjects in botany. No limits can be found in *Cereus*; the same is true of *Illicium*, and several similar plants. In all *Liliaceæ*, *Orchidaceæ*, and *Zingiberaceæ*, the only distinction that can be drawn between the calyx and corolla is, that the one originates within the other; they are alike in figure, colour, texture, odour, and function. Whatever therefore has been proved to be true of the calyx is also true of the corolla. There are also cases in which the petals have actually reverted to the state of leaves. In a *Campanula Rapunculus*, seen by Röper, the corolla had become five green leaves like those of the calyx; the same was found in a *Verbascum pyramidatum*, described by Du Petit Thouars; proliferous flowers of *Geum* and *Rosa*, in which the petals were converted into leaves, are adduced by Linnæus.

The third whorl or series of fructification is occupied by the stamens. These often consist of a single row, equal in number to the divisions of the corolla, with which they are in that case alternate. The exceptions to this in flowers with a definite number of stamens are not numerous; and such as do occur are to be considered as wanting the outer row of stamens, and developing the second row instead. Thus in *Primulaceæ*, in which the stamens are opposite to the petals, and therefore belonging to a second whorl, the first makes its appearance in *Schwenckia* in the form of clavate or subulate processes arising from the sinuses of the limb. These and similar processes, which are far from uncommon in plants, and which are known by various names, such as scales of the orifice of the corolla, glands, nectary, cup, &c., are in most cases metamorphosed stamens. In *Narcissus* the cup is formed of three stamens of the first row, become petaloid and united at their margins; while the six which form the second and third rows are in their usual state and within the tube. This is shown, firstly, by the frequent divisions of this cup into three lobes, which then alternate with the petals; secondly, by a distinct tendency in double *Narcissi*, particularly *N. poeticus*, to produce abortive anthers on the margin of the lobes of the cup; and thirdly, by the genus *Brodiaea* and its allies. In that genus the crown of the original species consists of three petaloid pieces, not united into a cup, as in *Narcissus*, but wholly separate from each other; in *Leucocoryne ixioides* these pieces are not petaloid, but clavate; and in *Leucocoryne odorata* the species have the same figure as in *I. ixioides*, but almost constantly bear more or less perfect anthers. That the anthers are mere alterations of the margins of petals, there is no difficulty in demonstrating. In *Nymphaea* the passage from the one to the other may be distinctly traced. In double roses the precise nature of this metamorphosis is shown in a very instructive way. If any double rose is examined, it will be seen that those petals which are next the stamens contract their claw into the form of a filament, and a distortion of the upper part, or limb, also takes place; the two sides become membranous, and put on the colour and texture of the anther; and sometimes the perfect lobe of an anther will be found on one side of a petal, and the half-formed, mis-shapen rudiment of another on the opposite side. In *Aquilegia vulgaris* this transformation is still more curious, but equally distinct: the petals of that plant consist of a long sessile purple horn or bag, with a spreading margin; while the stamens consist of a slender filament, bearing a small oblong, two-celled, yellow anther. In single and regularly-formed flowers nothing can be more unlike than the petals and stamens; but in double flowers the transition is complete; the petals, which first begin to change, provide themselves with slender unguis; the next contract their margin, and acquire a still longer unguis; in the next the purple margin disappears entirely; two yellow lobes like the cells of the anther take

its place, and the horn, diminished in size, no longer proceeds from the base, as in the genuine petal, but from the apex of the now filiform unguis. In the last transition the lobes of the anther are more fully formed, and the horn is almost contracted within the dimensions of the connective, retaining however its purple colour: the next stage is the perfect stamen. The conversion of stamens into green leaves is far more uncommon: this indeed very rarely occurs. It was seen by Röper in the *Campanula Rapunculus* already referred to; and Du Petit Thouars found the stamens of *Brassica napus* converted into branches bearing verticillate leaves. In *Plantago major* and *Sieversia montana* permanent instances are known of a conversion of the stamens, with all the other floral organs, into leaves. Thus it appears that the stamens, like the petals, calyx, and bractes, are merely modified leaves.

The disk is so frequently absent, and is of so obscure a nature, that few morphologists take it into their consideration. In many plants it consists of a mere annular fleshy ring encompassing the base of the ovary; in others it forms a sort of cup, in which the ovaries are enclosed, as in certain *Pæonies*, and it very frequently makes its appearance in the form of hypogynous glands or scales: it is almost always between the stamens and pistil. That it is not an organ of a distinct nature may be inferred from its having no existence in a large number of flowers; but if it is not an organ of itself, it must be a modification of something else, and in that view, from its situation, it would be referrible either to the stamens or pistil. It has so little connection with the latter, from which it always separates at maturity, that it can scarcely belong to it. With the stamens it has a stronger relation: it consists of the same cellular substance as the connective of the anthers, is very often of the same colour; whenever it separates into what are called hypogynous glands or scales, these always alternate with the innermost series of stamens. In the *Pæony* the disk may in some measure be compared to the inner row of scales which exist between the stamens and pistil of the nearly-related genus *Aquilegia*. Dunal has noticed half the disk of a *Cistus* bearing stamens; and a variety of instances may be adduced of an insensible gradation from the stamens to the most rudimentary state of the organ.

The fifth and last series of the fructification is the pistil. The simple pistil, that of the pea for instance, consists of an ovary, bearing its ovules on one side in two parallel contiguous rows, and at its upper extremity tapering into a style, which terminates in a stigma. If this organ be further examined, it will be found that there is a suture running down each edge from the style to the base; it will be also seen that the ovules are attached to one of these sutures, and that the style is an elongation of the other: further, it will be perceived that the two sides of the ovary are traversed by veins emanating from the suture that terminates in the style, and that these veins take a slightly ascending direction towards the suture which bears the ovules. Now if, when the pod of the pea is half grown, it be laid open through the latter suture, all these circumstances will at that time be distinctly visible; and if it then be compared with one of the leaflets of the plant, it will be apparent that the suture that bears ovules answers to the two edges of the leaf, the suture without ovules to the midrib, and the style to the mucro. Hence it might, without further evidence, be suspected that the ovary is an alteration of the leaf; but if the inquiry be carried further in other plants, this suspicion becomes converted into certainty. In the first place, the suture without ovules, which has been said to be the midrib, is always external with respect to the axis of fructification, as would be the case with the midrib of a leaf folded up and terminating the fructification. In the next place, nothing is more common than to find the pistil converted either into petals or into leaves. Its change into petals is to be found in numerous double flowers, as for example double *Narcissi*, *Hibiscus Rosa sinensis*, wall-flowers, ranunculuses, saxifrages, and others. These however only show its tendency to revert to petals as the representatives of leaves. The cases of its reverting to other organs are much more instructive. In the double *Ulex Europæus* the ovary is extremely like one of the segments of the calyx; its ovuliferous suture is not closed; in the room of ovules it sometimes bears little yellow processes like miniature petals, and its back corresponds to what would be the back of the calyx; no style or stigma is visi-

ble; sometimes two of these metamorphosed ovaries are present: in that case the sutures which should bear ovules are opposite to each other, just as the inflexed margins of two opposite leaves would be. In *Kerria Japonica*, which is only known in our gardens in a double state, the ovaries are uniformly little miniature leaves, with serrated margins corresponding to the ovuliferous suture of the ovary, and an elongated point representing the style; their interior is occupied by other smaller leaves. Nothing is more common among roses than to find the ovaries converted into perfect leaves; in such cases the margins uniformly occupy the place of the ovuliferous suture, and the midrib that of the sterile suture. But the most instructive and satisfactory proof of the pistil being merely a modified leaf is to be found in the common double cherry of the gardens. In this plant the place of the ovary is usually occupied by a leaf altogether similar to those of the branches, but much smaller: it is folded together; its margins are serrated, and, in consequence of the folding, placed so as to touch each other; and they occupy the place of the ovuliferous suture of a real pistil. The midrib of this leaf corresponds to the station of the sterile suture of the ovary, and is not only lengthened into a process representing a style, but is actually terminated by a stigma. There is thus a greater identity of function between the pistil and the other series of the fructification than would at first appear probable. The pistil is seldom indeed found converted into stamens; but it often takes upon itself the form of petals, as has been shown above; and although cases are very rare of pistils bearing pollen, yet several instances are known of ovules being borne by the stamens. This occurs continually in *Sempervivum tectorum*.

It appears then that there is not only a continuous uninterrupted passage from the leaves to the bracts, from bracts to calyx, from calyx to corolla, from corolla to stamens, and from stamens to pistil, from which circumstance alone the origin of all these organs might have been referred to the leaves, but that there is also a continual tendency on the part of every one of them to revert to the form of a leaf.

The pistil in a state of composition differs much in appearance from its simple form. At section 78 of *Die Metamorphose der Pflanzen* of Göthe, are the following remarkable words:—'Keeping in view the observations that have now been made, there will be no difficulty in discovering the leaf in the seed-vessel, notwithstanding the variable structure of that part and its peculiar combinations. Thus, the pod is a leaf which is folded up and grown together at its edges, and the capsule consists of several leaves grown together; and the compound fruit is composed of several leaves united round a common centre, their sides being opened so as to form a communication between them, and their edges adhering together. This is obvious from capsules, which, when ripe, split asunder, at which time each portion is a separate pod. It is also shown by different species of one genus, in which modifications exist of the principle on which their fruit is formed: for instance, the capsules of *Nigella orientalis* consist of pods assembled round a centre, and partially united; in *Nigella damascena* their union is complete.'

As it may thus be proved that all the parts of a flower are merely modified leaves, the following propositions may be stated to constitute the basis of morphology:—

'Every flower, with its peduncle and bracteola, being the development of a flower-bud, and flower-buds being altogether analogous to leaf-buds, it follows as a corollary, that every flower, with its peduncle and bracteolæ, is a metamorphosed branch.

'And further, the flowers being abortive branches, whatever the laws are of the arrangement of branches with respect to each other, the same will be the laws of the arrangement of flowers with respect to each other.

'In consequence of a flower and its peduncle being a branch in a particular state, the rudimentary or metamorphosed leaves which constitute bractes, floral envelopes, and sexes, are subject to exactly the same laws of arrangement as regularly formed leaves.' (*Lindley's Outline of the First Principles of Botany*, edit. 2.)

Therefore all theories of structure inconsistent with these propositions must be vicious.

The reader who would occupy himself further with this curious subject, may consult Martius's edition of the *Œuvres d'Histoire Naturelle* de Göthe, Paris, 1837;

Miquel's *Commentatio de Organorum in Vegetabilibus Ortu et Metamorphosi*, Lugd. Bat., 1833; and Röper's *Treatise De Organis Plantarum*.

Engelmann has moreover (*De Antholysti Prodrum*) attempted to classify the principal aberrations from normal structure, and has collected a very considerable number of cases under the following heads:—

1. Retrograde metamorphosis (*Regressus*), when organs assume the state of some of those on the outside of them, as when carpels change to stamens or petals, hypogynous scales to stamens, stamens to petals or sepals, sepals to ordinary leaves, irregular structure to regular, and the like.
2. Foliaceous metamorphosis (*Viroscentia*), when all the parts of a flower assume more or less completely the state of leaves.
3. Disunion (*Disjunctio*), when the parts that usually cohere are separated, as the carpels of a syncarpous pistillum, the filaments of monadelphous stamens, the petals of a monopetalous corolla, &c.
4. Dislocation (*Apostasis*): in this case the whorls of the flower are broken up by the extension of the axis.
5. Viviparousness (*Dia-physis*), when the axis is not only elongated, but continues to grow and form new parts, as in those instances where one flower grows from within another.
- And, finally, 6. Proliferousness (*Echhlustasis*), when buds are developed in the axils of the floral organs, so as to convert a simple flower into a mass of inflorescence.

A very considerable number of instances are adduced in illustration of these divisions, and the work will be found highly useful as a collection of curious or important facts.

METAPHOR (*μεταφορά*, literally 'a transference'), a figure of speech which renders the subject of discourse striking, by the aid of expressions primarily referring to other objects. A common kind of metaphor is that called personification, where inanimate beings are represented as endowed with life, and even with feeling, reason, &c., as 'the fields do laugh and sing,'—'stern winter.' If this kind of metaphor spiritualises the corporeal, another kind, on the contrary, embodies the spiritual, as 'the star of renown'—'the pinnacle of honour,' and so on. A third kind is little else than a shortened simile, two objects in the same sphere being brought together, only on account of their resemblance. To this kind belong such expressions as 'the silver moon'—'the golden sun,' &c., where it will be seen at once that 'silver' and 'moon,' 'gold' and 'sun,' are connected merely on account of their obvious similarity of colour and brightness. The origin of the first two kinds of metaphor is not so apparent, for though they likewise express a similarity, yet the similarity of a series of bodily objects to a series of objects merely of the mind, where there can of necessity be no sensible resemblance, is a subject for psychological investigation. The application of certain metaphors, in all languages and among all people, attracted the attention of Jean Paul Richter, who remarked that 'no nation called error, light, or truth, darkness.' If we attend to the state of language, we shall find that a great part of the commonest discourse is composed of metaphors of the second kind, and that nearly all words expressing mental states, operations, and affections are in fact metaphorical. Thus we say every day 'a man of extended views'—'a man of good capacity, acute judgment,' &c., where the words 'extended,' 'views,' 'capacity,' 'acute,' evidently belonged originally to material objects, but have been applied to things immaterial by metaphors. The circumstance that material objects are more apparent, that language seems primarily to have them for its sole objects, and that when a higher degree of reflection brings with it objects belonging to the mind alone, nothing is left but to apply in a new sense the words already formed, is sufficient to explain the use of these metaphors generally. But still the fact that such and such bodily attributes are universally predicated of such and such spiritual objects alone, may still furnish matter for consideration to the curious in psychological speculation.

METAPHYSICS, a name originally applied to those books of Aristotle which followed his 'Physics,' and which his editors called 'the books after the Physics' (*μετὰ τὰ φυσικά*). In modern times the word has been variously applied, and seems to assume quite a distinct meaning as employed by different authors. With the Germans, metaphysics is a science purely speculative, which soars beyond the bounds of experience. The objects of this science are supersensual ideas, unattainable by experience, and the difficulty of defining the word lies in the circumstance that

the very knowledge of the ideas sought requires some proficiency in the study. Hence to one altogether unacquainted with speculative philosophy it is almost impossible to explain the meaning of the word 'metaphysics' as used in this sense. The very possibility of a science beyond experience has been denied by a great number of philosophers, and many works called metaphysical should rather be termed inquiries into the possibility of metaphysics. Thus Kant's celebrated work, the *Critik der reinen Vernunft*, is a mere inquiry into the possibility of a theoretical science of things beyond experience, which terminates with a denial of such possibility, and hence some modern philosophers have considered Kant as no metaphysician, but as a critic of the mental faculties, whose labours were to be the precursors of a new system of speculation. On the other hand, a work like Spinoza's 'Ethics' is purely metaphysical. He assumes the possibility of his science, and, proceeding from a number of axioms, speculates accordingly. Those who deny the possibility of metaphysics deny even the right to assume any axioms as applicable to a sphere beyond experience; and those who did assume them, as Spinoza, Leibnitz, and Wolf, were called by the Kantians dogmatists, in opposition to their own appellation of critics. The great point to be established prior to metaphysical speculation is the identity, or at least the necessary concurrence, of thought and being. This once established, speculative inquiry may proceed, as the results of logical investigation must in such a case, of course, concur with the nature of being itself; but the sceptics always deny the right of assuming such identity or concurrence, while on the other hand different theories have been adopted to prove them, such as those of harmony between body and spirit,—of the non-being of body altogether, except as an affection of spirit,—of an absolute identity between thought and being, &c. It may be as well to observe that the critical philosophy, which assumes nothing but the 'I' or 'ego,' and the laws of thought (Fichte deducing even the latter from the axiom, 'I am I'), has Descartes for its author, whose 'Cogito, ergo sum,' lies at the basis of most modern systems. [DESCARTES.]

In England, the word metaphysics is usually applied to denote the philosophy of mind, as distinguished from that of matter. This science treats of the association of ideas, memory, and various phenomena of mind; and as it consists merely in collecting facts and making inductions like any other experimental science, its possibility is no more questionable than that of chemistry or electricity. However, Locke's 'Essay on the Human Understanding,' as a denial of any source of knowledge other than experience, may be put at the side of Kant's 'Critik,' as containing inquiries of a similar nature, though the results be different; Berkeley's 'Idealism' may be compared with the 'Wissenschaftslehre' of Fichte, and the common-sense theory of Reid with the views of Jacobi. The philosophy of mind as an experimental science has been chiefly treated by the modern Scotch philosophers.

METASTASIO, PIETRO, was born at Rome, on the 6th of January, 1698. His father, once an opulent citizen of Assisi, afterwards a soldier, then an amanuensis, and finally a small pastrycook at Rome, was enabled, by the profits of his trade, to place his son at a little grammar-school, where he soon displayed that talent for poetry which so highly distinguished him in after-life. Before he was ten years old, says his biographer, Dr Burney, he could make verses on any subject, and it was no unusual sight to see his father's porch surrounded in the evening, after school hours, by groups listening to the poesy of a child. During one of these tuneful sittings, the celebrated lawyer and critic Gravina happened to pass by, and was forcibly struck by the extraordinary talent displayed by the youthful improvisatore. He offered the young poet money, which was refused in a manner so firm, yet so polite, that Gravina's admiration of him was increased, and he instantly formed the resolution of adopting him. The father, Felice Trapassi, willingly consented, and the next morning Pietro was consigned to the care of his patron, who changed his name to Metastasio (*Μεταστάσις*, *mutatio*, a changing), a term expressing his situation by adoption.

Gravina immediately determined to educate his charge for the profession of the law, wishing rather that he should become an orator than a poet, well knowing that the former profession leads to fortune, and the latter, most commonly, to empty fame. He nevertheless caused him to study the

antient poets, in which pursuit his ardour and success were so great, that at the early age of fourteen he produced his tragedy *Giustino*, written after the Greek models. His patron now not only allowed but encouraged his devotion to the muses; and when Metastasio had reached his eighteenth year, Gravina accompanied him to Naples, that he might meet and sing with the most eminent improvisatori of the day. He became a universal favourite. The harmony of his verse, the grace and dignity of his elocution, and the expressiveness of his countenance, were the topics of all conversations. Still he continued to study the law; and, to secure an opening into the only other road to preferment, entered into a minor order of priesthood.

Within two years after his arrival at Naples, his patron died, and Metastasio mourned his loss like an affectionate son. By Gravina's will he became sole possessor of all his property, consisting of 15,000 crowns, a fine library, and a little estate in the kingdom of Naples. But such was the generosity, not to call it by a harsher name, of the poet's disposition, that, in the short space of two years, all that remained to him of this property was the small landed estate. He now applied to the law, and during a whole year was most assiduous in his studies under Paglietti, a mortal enemy to the muses. But at the end of that time he was again attracted to his poetic pursuits, and produced an *Epithalamium*, at the request of the Countess of Althau, who likewise prevailed on him to write the drama *Endimione*. Under the patronage of the viceroy of Naples, he next produced *Gli Orti Esperidi* (the *Gardens of the Hesperides*), and then *Angelica*, the plot from Ariosto. The former of the two was most successful, and especially admired by Signora Bulgarini, better known as the *Romanina*. She was the first singer of her day, and performed the part of *Venus* in the favoured opera. Such were her admiration and esteem for the author, that she persuaded him to renounce the law, to take up his abode under her husband's roof, and to dedicate the whole of his energies and time to the muses and to friendship. Feeble was the struggle between Paglietti and the *Romanina*: he acceded to the tempting proposal, and henceforward

* Apollo beat Ma'am Themis hollow.

His *Didone Abbandonata* was written at the request of his female friend, to whom, it has been surmised, the poet is indebted for some of the finest dramatic incidents. Such was the celebrity of this drama, that it was set by all the great Italian composers of that period, and not only established the author's fame, but brought him a large pecuniary recompense. In 1727 he accompanied the *Romanina* to Rome, where he produced his *Semiramide*, *Ezio*, *Alessandro nell' Indie*, *Catone in Utica*, and the opera so well known by our English version of it, *Artaserse*. But praise was nearly the whole of the reward he reaped from his labours in the pope's dominions.

In the year 1729 Metastasio received an invitation from the court of Vienna, whither he repaired, and became the successor of Apostolo Zeno, the Imperial laureate. This appointment was rendered more gratifying to him, as it was made on the recommendation of Zeno himself, who had long enjoyed the office, and had written a vast number of lyrical dramas, among which are many of the best that the Italian language can boast. [ZENO.] The stipend assigned to Metastasio was considerable for that time—3000 florins was then a large salary; and other advantages were added. This came rather opportunely, for at Rome he had suffered much from the slenderness of his income, and was often indebted to his friend for assistance. To her, when he left Italy, he entrusted his affairs, and deposited with her a small sum for the temporary support of his father, till he could make an arrangement of a permanent kind. His reception by Charles VI. was most gratifying, and promised everything for the future, a promise not disappointed. During the succeeding three years, his correspondence with his 'inestimable counsellor and friend' amounts almost to an autobiography; but in 1734 he sustained an irreparable loss by her death, who to the last proved the sincerity of her attachment by bequeathing to him, after the decease of her husband, the whole of her property, amounting to 25,000 crowns. Metastasio however, guided in this instance, as he was in every other, by the strictest rules of honour, declined to derive any advantage from the will so generously made in his favour, and imme-

diately transferred to the husband all right to the rever-sionary property. What may have been the nature of the connection between the poet and Signora Bulgarini (or the *Romanina*), it is now impossible to say. From Metastasio's letter to the husband on the death of his wife, the sorrow expressed is in a tone of candour which looks as if there had been nothing to conceal or disguise. He says, 'I know not how to begin this letter. The tidings are so intolerable to me on many accounts, that I can devise no means to diminish the acuteness of my sufferings; therefore I trust you will not accuse me of want of feeling if I am unable to suggest to you any consolation for your loss, as I have hitherto been totally unequal to finding any for myself.' At what age the lady died is unknown, but as she was first singer at Genoa in 1712, it is likely that she was much the senior of her friend.

Metastasio's mode of life, from his first settling in Vienna till the moment of his death, was that of a poet and man of letters, who devoted his time and thoughts to the muses, to general literature, and to the conversation of persons more or less connected with his pursuits. In 1733 he produced, among other pieces, *L'Olimpiade*, which the Italians distinguish as *il divino*, and his very popular canzonetta, *La Libertà*. For the emperor's birth-day in 1734 he wrote the noble opera, so well known in every part of Europe, *La Clemenza di Tito*, which was set by the Imperial composer, Caldara, but not a vestige of the music remains. The same drama however was in 1790 chosen by Mozart, whose magic notes have assisted in bestowing on it immortality. It is not unworthy of remark, that though all the poet's operas were set as soon as written, yet not even a single piece of the original music is now known, or, we believe, to be found, except perhaps in the Imperial library of Vienna.

He continued supplying the court with lyric dramas and oratorios, and also employed himself in the production of various detached pieces of poetry, till the year 1740, when the death of the emperor brought on the long and devastating war in Germany, and this led to the closing of the theatre, for which he had so successfully laboured. He now employed his pen in translating into blank-verse the *Ars Poetica* of Horace, together with one of his Satires and Epistles, and Juvenal's third Satire. He likewise wrote notes on the Greek tragedians, and translated a portion of Aristotle's 'Poetic,' adding a very learned, luminous, and ingenious commentary, which appeared in print after his decease. But though his dramatic labours for the Imperial city were suspended, he produced in 1744 *Antigono* for the court of Dresden, and *Ipermestra* in the same year. His health however appears now to have suffered from the anxieties occasioned by the long war, and he entertained serious thoughts of hastening back to Rome; but the return of peace operated on him like a charm; it removed the nervous disease which had hung on him, it restored his wonted tranquillity, and in 1751 he wrote *Il Re Pastore* for the ladies of the Imperial court, by whom it was performed, and the 'bold sentiments on the duty of sovereigns, which he ventured to put into the mouth of one of characters, do equal honour, Dr. Burney remarks, to his Imperial patrons, who could listen to them with pleasure, and to the laureate who had the courage to preach them.' His last drama was *Il Ruggiero*, performed in 1771 at Milan, on the marriage of the archduke Ferdinand.

Of Metastasio's seven sacred dramas, or oratorios, *La Passione*, *La Morte d'Abel*, and *Isacco* are best known; but all of them, Calsabigi justly observes, are as perfect as this kind of composition will allow. Of his cantatas, *La Primavera*, *La Libertà*, and *La Partenza* are admired by all who have any acquaintance with Italian poetry. His occasional short dramatic pieces, sonnets, and other miscellanies are too numerous to be mentioned here; a *catalogue raisonné* of them is given in the work whence we have drawn most of our materials for the foregoing portion of this article. (Dr. Burney's *Memoirs of Metastasio*.)

One of the occupations of the poet when far advanced in years was the preparing corrected copies for the magnificent edition of his works printed at Paris in 1780. This may be considered his last labour. On the first of April, 1782, he was attacked by symptoms of fever, alarming at his age, and on the 12th he expired. His remains were deposited in the church of St. Michael at Vienna. His property, consisting of a well furnished house, carriage, &c., many princely presents, an ample library, and 130,000

florins, he bequeathed to the son of his old friend Signor Martinetz, whose house was his first abode in Germany: but from this sum were to be deducted 20,000 florins for each of the executor's sisters, and 3000 for each of his younger brothers.

The genius of Metastasio, says Arteaga, 'may be compared to the goddess Chloris of the Greeks, who, in flying through the air, scattered roses wherever she went.' He did indeed ornament and cast a fragrance on whatever he touched. His reputation soon obscured that of Apostolo Zeno. W. Schlegel observes, because, having the same object in view, he showed more flexible talent, and knew better how to adapt himself to the views and means of the composer. A perfect purity of diction, adds the same acute critic, a grace and unalloyed delicacy, have rendered Metastasio, in the eyes of his countrymen, a classic author, the Racine of Italy. He has above all a ravishing softness in his verses designed for music. Perhaps no poet ever possessed in the same degree the gift of compressing in a short space situations so pathetic, so touching. It is said of him, by Schlegel, that in order not to endanger his originality, he carefully abstained from reading the chefs-d'œuvre of the French stage. However this may be, we will add, that in all his works it is clear that he was no imitator: his style, his chasteness, his tenderness, were his own. In deep tragedy he could not excel; he had not the power to wring the heart; his life was too serene, he was too happy in himself to imagine scenes of bitter anguish, of complicated misery; but in depicting gentle grief, that grief which does not pass the confines of reason, he has no superior. He has been described as, *par excellence*, the poet of love, but his most passionate expressions never are sullied by the slightest breathing of indelicacy. His morality is unimpeachable, is exemplary. In all his works he stands high; in his operas he is unrivalled.

METATARSUS. [SKELETON.]

METELLI, a distinguished family of the Cæcilian gens in ancient Rome. Those most worthy of notice are—

1. Q. Cæcilius Metellus Macedonicus, who was sent when prætor (B.C. 148) into Macedonia against Andriscus, who pretended to be a son of Perseus, the last king of Macedonia, and who had excited a revolt against the Romans. In this war Andriscus was defeated and taken prisoner by Metellus. (Liv., *Epit.*, 50; Paus., vii. 13, 1; Eutrop., iv. 13.)

In B.C. 146, Metellus defeated the Achæans near Thermopylæ, and on his return to Rome obtained a triumph on account of his conquest of Macedonia. (Liv., *Epit.*, 52.) Metellus, in his consulship, B.C. 143, was sent into Spain to oppose Viriathus, who had obtained possession of the whole of Lusitania, and had defeated successively the prætors Vetilius and Plautius. Metellus remained in Spain two years, and obtained several victories, but was succeeded in the command, before the conclusion of the war, by Q. Pompeius. (Liv., *Epit.*, 52, 53; Val. Max., iii. 2, 21; vii. 4, 5; ix. 3, 7; Appian, *Iber.*, 76; Eutrop., iv. 16.)

During the censorship of Metellus and Q. Pompeius, B.C. 131, it was decreed that all citizens should be obliged to marry. The oration which Metellus delivered on this subject was extant in the time of Livy, and is referred to by Suetonius (Liv., *Epit.*, 59; Suet., *Octav.*, 89.) We are told by Livy and Pliny that when Metellus was returning one day from the Campus Martius, he was seized by command of C. Attinius Labæo, a tribune of the plebs, whom he had in his censorship expelled from the senate, and dragged to the Tarpeian rock; and that it was with the greatest difficulty that his friends were enabled to preserve his life by obtaining another tribune to put his veto upon the order of Attinius. (Liv., *Epit.*, 59; Plin., *Hist. Nat.*, vii. 45.)

Pliny refers to Metellus as an extraordinary example of human happiness. 'For besides the possession of the highest dignities,' says Pliny, 'and having obtained a surname from the conquest of Macedonia, he was carried to the funeral pile by four sons, of whom one had been prætor, three had been consuls, two had enjoyed a triumph, and one had been censor.' (*Hist. Nat.*, vii. 45.)

2. Quintus Cæcilius Metellus Numidicus derived his latter cognomen or surname from his victories in Numidia, whither he was sent in his consulship, B.C. 109, in order to oppose Jugurtha. He remained in Numidia, B.C. 108, as proconsul; but in the beginning of the following year he was superseded in the command by Marius, who had formerly

been his *legatus*, or lieutenant-general. On his return to Rome, Metellus obtained the honour of a triumph. (Sallust, *Bell. Jugurth.*; Vell., ii. 11; Eutrop., iv. 27; Liv., *Ep.*, 65.) [JUGURTHA.]

Metellus was censor B.C. 102. He took an active part in the civil commotions of his time, and was one of the most powerful supporters of the aristocratical party. In B.C. 100 he was obliged to go into exile in consequence of opposing the measures of the tribune Saturninus; but on the execution of the latter, Metellus was recalled from exile in the following year. [MARIUS.]

3. Q. Cæcilius Metellus Pius, son of Numidicus, belonged to the same political party as his father, and supported Sulla in his contest with Marius. Metellus received especial marks of favour from Sulla, and was consul with him, B.C. 80. In B.C. 78 Metellus was sent against Sertorius in Spain, where he appears to have remained till the conclusion of the war, in B.C. 72. From the year 76 Pompey was his colleague in the command; and they triumphed together at the end of the war. [SERTORIUS.] (Vell., ii. 30; Eutrop., vi. 5; Plut., *Pomp.*) Metellus was Pontifex Maximus; and on his death, B.C. 63, in the consulship of Cicero, he was succeeded in that dignity by Julius Cæsar.

METEMPSYCHOSIS (*μετεμψύχωσις*), derived from a Greek word signifying the passage or transmigration of souls, forms a part of the philosophical or religious belief of many nations. The Hindus believe that the souls of men pass after death into different bodies, either of men or animals, unless an individual has lived a most holy and religious life; in which case his soul is absorbed into the divine essence. 'The soul passes from one state to another invested with a subtle frame consisting of elementary particles, the seed or rudiment of a grosser body. Departing from that which it occupied, it ascends to the moon, where, clothed with an aqueous form, it experiences the recompense of its works; and whence it returns to occupy a new body with resulting influence of its former deeds. But he who has attained the true knowledge of God does not pass through the same stages of retreat, but proceeds directly to reunion with the Supreme Being, with which he is identified, as a river at its confluence with the sea merges therein altogether. His vital faculties and the elements of which his body consists are absorbed completely and absolutely; both name and form cease; and he becomes immortal without parts or members.'

('Extracts from the *Brahma-sûtras*, or Aphorisms on the Vedanta doctrine, by Bâdarâyana,' translated by Mr. Colebrooke, in *Trans. of the Roy. As. Soc.*, vol. ix.)

The migration of souls from one body to another also formed, as is well known, a leading feature of the Pythagorean doctrine, and seems also to have been maintained by Plato, although there is considerable difficulty in ascertaining the opinions of Plato on this subject. This doctrine was also a part of the Egyptian religious system. The Egyptians, says Herodotus (ii. 123), are the first who believed in the immortality of the soul. As soon as the body begins to decay, the soul passes from one animal to another; and when it has passed through the forms of all animals, terrestrial, aquatic, and winged, it again enters a human form. This period of transmigration is completed in 3000 years. Some of the Greeks, he adds, both in early times and more recently, have maintained this doctrine and claimed it as their own; and though he could mention names, he declines to do so.

METEOROLOGY, in its extended sense, embraces all physical causes which affect the state of the atmosphere or are affected by it. Hence it is connected with the phenomena of heat and cold, dew, rain, hail and snow, clouds, winds, auroræ boreales, haloes, parhelia, &c. The sense in which Aristotle (*Μετεωρολογικά*, i.) uses the term is still more extensive, comprehending, in addition to what are now called meteors, every affection (*πάθος*) common to the air and water, with the characters of the different parts of the earth, and their affections, as winds and earthquakes, and everything incident to such kinds of motion.

Our first inquiry shall be, what is the nature and what the probable extent of the terrestrial atmosphere? Essential as it is both to animal and vegetable life, to the distribution of heat, and to various modifications of light, the knowledge of its nature and composition is eminently useful. The air, though composed of several elastic fluids, obeys the same laws to which they are individually subject, namely, its elasticity and density at a given temperature

are proportional to the pressure which it sustains, and for every degree of the centigrade thermometer under a given pressure it expands $\frac{1}{273}$ of its volume at the temperature zero. Hence if its density be represented by δ and its temperature by t (in centigrade degrees), its elastic force will be proportional to $(1 + \alpha t) \cdot \delta$ (where α represents the decimal .00375) as well as the pressure sustained. Lastly, the pressure is equal to the weight of a vertical column of atmosphere, having the portion pressed on as a base, and extending upwards to its extreme limit.

According to Dalton's views, the various constituent gases constituting the air are not chemically combined by the law of definite proportions, but only mechanically mixed, co-existing in the same space, and producing by the sum of their independent pressures the elevation of the mercury in the barometric tube: an ingenious theory, which however appears open to objections from the known laws of the specific gravities of fluids.

We have seen that heat increases the elastic power of air, and hence the equilibrium of a mass of air unequally heated is constantly disturbed. The currents of warm and cold air change places, the cold air moving to the warm region, and thence, when warmed, repeating the course of the previous warm air. Thus the atmosphere is a great agent in tending to equalise the mean temperatures of climates in various latitudes. Besides, the aerial currents are vehicles for the transfer of clouds, for producing electrical discharges, for clearing away malaria, and are turned by the ingenuity of man to promote his industry and extend his knowledge of the globe which he inhabits.

The atmosphere, considered as a transparent medium, has also great effects on light by its refractive power, and the reflection of the aqueous masses it contains. Hence arises twilight, which mitigates the transition of day to night, and from the duration of which it is easy for the astronomer to compute that altitude of the atmosphere at which it ceases to act sensibly on light, either from its total absence or extreme tenuity. This altitude is from forty to fifty miles above the level of the sea. Again, by the refractive power of the atmosphere distant terrestrial objects are elevated to the view when the spherical curvature of the earth would otherwise have caused their concealment; various optical illusions, as the mirage, fata morgana, &c., are all easily explained from the same refractive power under peculiar circumstances of temperature. By this medium sound is conveyed and odours are disseminated; the clouds which float in it soften the direct glare of the solar beams, and its aqueous particles, fluid or frozen, produce the beautiful phenomena of halos, rainbows, false suns, &c. Its greater specific gravity elevates the balloon, by means of which the nature of the upper strata of the air may be ascertained, and the barometric elevation and temperature observed, which furnish data for calculating the physical limits of the atmosphere.

With regard to the extent of the atmosphere, we may consider it under two points of view: first, the extreme limits to which it is possible for it to extend, considered mathematically as a mass rotating round the terrestrial axis in the same time; secondly, the much narrower physical limits founded on its nature as an elastic fluid, and having regard to the great diminution of temperature at high altitudes.

Any particle of the revolving atmosphere is acted on by two forces, namely, gravity, which is directed nearly to the centre of the earth, and the centrifugal force produced by rotation, which is directed according to the line by which that point is orthographically projected on the earth's axis, and tends directly from that axis. The former force varies inversely as the square of the distance from the earth's centre; the latter, directly as its perpendicular distance from the earth's axis. At any point taken in the external surface of the atmosphere, the resultant arising from both forces must be normal to that surface, in order that its form may be permanent. At the terrestrial equator the ratio of these two forces is known; as we ascend in the atmosphere along an equatorial radius produced, gravity diminishes and centrifugal force increases, both in this instance being directly opposite: hence it is easy to calculate the distance of a point in that radius where the two forces are exactly equal. Beyond that point the centrifugal force predominates, and no particle there situated could remain attached to our atmosphere, revolving with the earth both in its diurnal and orbital motions.

The above point therefore defines the extreme limit to which it is possible for our atmosphere to extend, and which is at a distance of about 25,000 miles from the centre, though it by no means follows that it must extend so far. Other data would be necessary to give the actual extent; for instance, the height of the barometer at the surface of the sea, and the law of the diminution of temperature in the upper strata of the air. The figure of the extreme surface can however be determined from these considerations, which is that of an oblate spheroid flattened at the poles, and in which the polar axis is to the equatorial in the ratio of 2 to 3.

As the phenomenon of twilight indicates an extreme degree of rarefaction in the atmosphere at an inconsiderable altitude above the earth's surface, we shall now consider some of the physical causes which demonstrate that the actual limits of that fluid are much more contracted than the extreme possible limits given above.

Representing by p , δ , and t respectively, the pressure, density, and temperature of the air at the surface of the earth, and by p' , δ' , and t' , like quantities for a portion of air at a certain elevation, it follows from the general laws

of gaseous bodies that $\frac{p'}{p} = \frac{(1 + \beta t') \delta'}{(1 + \beta t) \delta}$, where β represents

the fraction $\frac{1}{273}$. Now the pressure measures the elastic force of the aerial particles: this elasticity cannot become negative, and ceases to exist when $p' = 0$, which may happen either because $(1 + \beta t') = 0$, or $\delta' = 0$. This last supposition would bring us to the consideration of the mathematical limits above treated on; the former, to the physical limits depending on the decrease of temperature at high altitudes: hence the air ceases to be an elastic fluid when $t' =$

$-\frac{1}{\beta} = -\frac{273}{1} = -273^\circ$ centigrade. Now the law of the

decrement of heat in the atmosphere proceeds in a progression quicker than an arithmetical, and as the plane of perpetual snow is at a comparatively small altitude in climates of mean temperature, it is easy to see that from 100 to 200 miles altitude would be sufficient to diminish the temperature to the above number of 266° below zero. Even if the simple law $p = (1 + \beta t) \delta$ was not strictly rigorous at such low temperatures as -266° centigrade, still a diminution of temperature for a given density would produce a diminution of elasticity, and scarcely interfere with the general conclusion arrived at from that law.

But even limits thus obtained would, in all probability, be still too extensive, for it is not necessary that the elasticity should be totally destroyed: it is sufficient that the repulsive power of two contiguous particles of air at that altitude shall be less than the force of gravity, and if these two forces are equal, it will be the extreme extent at which the air can remain attached to the globe, leaving out of consideration the centrifugal force, which at that altitude is inconsiderable, and which would itself tend to remove those particles. Hence the limits become still more contracted by this consideration, and it will not be necessary that the temperature should be as low as -266° .

Some have imagined that planetary atmospheres are due to the attraction of the masses of the planets on a rare elastic fluid disseminated through space, but this supposition will not bear investigation; for putting aside the consideration of the extreme cold of the planetary spaces, this hypothesis is not corroborated by the dimensions of the atmospheres of the sun and planets, which would then depend on their masses, and the present total disappearance of the satellites of Jupiter behind their primary would be converted into an annular appearance round his body at the time of the eclipse of a satellite.

We have seen that the unequal distribution of heat in the atmosphere is a main source of the velocities and directions of winds, and consequently of the distribution of climate; but on the other hand, the earth itself, having its own distribution of heat, reacts on the atmosphere and produces dew, hoar-frost, &c. In like manner the sea and the Polar fields of ice materially affect the general distribution of heat.

The general causes of the temperature of the globe are the proper heat of the earth and the radiation of the sun; their effects however are greatly modified by various local circumstances, such as the vicinity of seas or mountains, and the radiating power of the soil, together with the con-

ducting powers of the strata subjacent to the particular places, with other causes less permanent.

With respect to the proper heat of the earth, we observe in any latitude that at a depth which is small compared with the radius of the globe, the temperature is permanent throughout the year, the effects of solar radiation being confined to a superficial stratum of inconsiderable thickness. This fact has been fully established by long continued observations in the cellars of the Observatory at Paris, and by observations in the mines of Cornwall, in Scotland and other countries. If this stratum be supposed to be stripped off, the internal nucleus may be considered as nearly a spherical mass, arrived at a permanent state of temperature in each part, and subject at its external surface to a given distribution of heat, or to a given power of exterior conductivity. The depth at which this permanence of temperature occurs is different in different latitudes, inasmuch as the solar action on the superior stratum is also different on account of the greater or less obliquity of its rays, and likewise on account of the earth's elliptic annual motion. Thus we have the following observed relations between the permanent temperatures and the corresponding latitudes:—

	Lat.	Permanent temperatures
Equator . . .	0°	78°
Cairo . . .	30°.2	72°.50
Paris . . .	48°.50	53°.60
Berlin . . .	52°.40	49°.28
Vadso . . .	70°	36°

The analytical equation for the propagation of heat in solids of any form, is—

$$\frac{dv}{dt} = K \left\{ \frac{d^2v}{dx^2} + \frac{d^2v}{dy^2} + \frac{d^2v}{dz^2} \right\},$$

where v represents the temperature at a point of which the rectangular co-ordinates are x, y, z , and the constant K depends on the interior conducting power, and t is the time. In the case of a sphere with a radius R , we may place the origin of co-ordinates at the centre, and transforming the above from rectangular to polar co-ordinates (viz. r , the distance from the centre, θ the angle formed by the radius vector with an axis, and ϕ the inclination of the plane of θ to one of the co-ordinate planes, the angles necessarily disappear from the transformed equation, and) it becomes

$$\frac{dv}{dt} = K \left\{ \frac{d^2v}{dr^2} + \frac{2}{r} \cdot \frac{dv}{dr} \right\},$$

on the supposition that the exterior permanent temperatures were uniform; to which we must annex the following

equation for the surface, $\frac{dv}{dr} + h(v - a) = 0$, where a represents the temperature of the medium in contact with the globe, and h the index of exterior conductivity of the globe. But in the case of the earth both K and h are variable, and the former must then be brought under the sign of differentiation. After there shall have been a greater number of observations on the permanent interior temperatures of the earth, the above equations will be very useful in enabling us to calculate the temperatures at depths under the surface greater than it is probable man can ever penetrate, and they will assist in the explanation of the numerous phenomena which depend on the internal heat of various parts of the globe, as volcanoes, thermal springs, &c. Regarding the interior parts which are sufficiently remote from the surface as in a state of permanent temperature, we should have $\frac{dv}{dt} = 0$; when the preceding equations admit of easy integration on the supposition that K is constant, and of approximate solutions on a probable form of the function K when variable.

With respect to the heat of the external stratum, it is principally dependent on the radiation of the sun, the effect of which depends on the duration and the obliquity of the solar rays, both of which are dependent on the declination of the sun and the latitude of the place. The integral taken throughout the year depends therefore solely on the latitude: from this integral the calculated mean temperature is derived, but differs in most cases from the observed inasmuch as the propagation of heat in the sea and in the air affects unequally those places in the same parallel which are near to or distant from the coasts, and the unequal quantity of continent in the northern and southern hemispheres produces a similar result with respect to them.

The direct heat of the sun being unequally distributed over different parts of the globe is the primary cause of the variation of climate; the effect of its rays is felt to a considerable depth in the sea, but its diurnal action on land is sensible only for a few inches in depth; the annual action however extends throughout the superior stratum of variable temperature above mentioned. The mean temperature of a place is generally estimated by taking the average of the diurnal temperatures during the four seasons of the year, and again taking the average of these four averages.

As there is a great variety of temperature in the same parallel of latitude, we cannot have a formula dependent only on this element to express the heat of places on continents, but in the sea there is much greater uniformity in this respect. The first approximate formula to that effect which deserves the name, is that given by Mayer, the celebrated astronomer; though empirical, it is found to possess considerable exactness. If t be the mean temperature in degrees of Fahrenheit's thermometer, he makes $t = 84 - 52 \sin^2 L$, where L is the latitude of the place. The supposed facts which evidently suggested this formula were the equatorial mean temperature of 64°, which is now generally supposed to be too high; the Polar mean temperature of 32°, or the freezing point, which, from the recent observations of Parry, Scoresby, &c., is now known to be far too great; and thirdly, that the diminution of heat from the equator to the poles must proceed according to some even power of the latitude in order to amount to the same quantity in equal latitudes north and south, for which reason he chose the least even positive power of the sine. However, since the quantity of land in the northern hemisphere is about three times as great as in the southern, the solar heat accumulates more in the former, and in the latter is more equable between winter and summer. Dr. Brewster has substituted for Mayer's the formula $t = 81°.50 \cos L$, which bears an exceedingly good comparison with observations, but for the reasons above given he has found it necessary to modify it for the New World. Mr. Atkinson has shown that the mean of the errors of Mayer's and Brewster's formulae for ten places nearly on the level of the sea are respectively $+1°.72$ and $-.12$. The temperatures of April and October are generally nearly the mean of the year, which also is found to vary but little in a considerable succession of years. If T be the mean temperature at an altitude h in feet, in a given place where t is the temperature of the surface, to express T , Mr. Atkinson has proposed the formula

$$T = t - \frac{h}{251 + \frac{h}{200}},$$

giving for the extreme atmospheric cold the temperature -200° , which is probably near the truth.

The names of Isothermal, Isocheimal, and Isothermal lines have been given to lines passing through places which have equal mean summer, winter, or annual temperatures, the two former having contrary courses, and the third intermediate. The difference of latitude between places in the New and Old Worlds, on the same isothermal line, is considerable, as appears from the following table:—

Isothermal line of Temperature.	Places.	Latitude.	Longitude.
32°	Near Uleo, Lapland, and	67°	20° E.
	Table Bay, Labrador	54°	58° W.
41°	Stockholm and	60°	18° E.
	St. George's Bay, Newfoundland	48°	59° W.
50°	Belgium and	51°	2° E.
	Boston, U. S.	42½°	71° W.
59°	Near Rome and	43°	11½° E.
	Raleigh, N. Carolina	36°	76½° W.

or we may average according to latitude thus:—

Latitude.	Mean Temperature of West of Old World.	Mean Temperature of East of New World.
30°	70°.52	66°.92
40°	63°.14	54°.50
50°	50°.90	37°.94
60°	40°.64	23°.72

The mean temperature in the latitude of 34° in different continents, and at places near the sea, is found to vary but little, thus:—

Places.	Continents.	Latitudes.	Temperature.
Cape of Good Hope	Africa	$33^{\circ} 51'$	$66^{\circ} \cdot 7$
Port Jackson, N. Holland	Australia	$33^{\circ} 53'$	$66^{\circ} \cdot 9$
City of Buenos Ayres	America	$34^{\circ} 36'$	$67^{\circ} \cdot 5$

The sea varies in temperature much less than the air; the region of warmest water extends about $5\frac{1}{2}^{\circ}$ on each side of the equator, but rather farther to the south than to the north; there appear to be two points of greatest cold near the North pole, attributable to the different propagation of heat in the New and Old Worlds above remarked. Dr. Brewster supposes them to be about 80° of lat., and situated in 95° E. and 100° W. long.; the temperature at these points appears to be decidedly below zero of Fahrenheit.

The production of winds in the atmosphere, we have already stated, is mainly attributable to the unequal distribution of heat in the atmosphere. The attractive action of the sun and moon on that fluid, though producing atmospheric tides, which have been recognised by barometrical observations, could only produce a tropical wind with a velocity of 4 miles per day, which would be evidently inappreciable amongst the numerous disturbances arising from temperature; but the heating action of the sun in tropical climates produces some well-known winds in the following manner.

On account of the annual accumulation of heat from the solar rays between the tropics, two currents of air from the north and south rush forward to occupy the place of the rarefied air of this region. Now since the earth in its diurnal rotation moves from west to east, these currents appear to deflect to the west on account of the increased velocity of the parallels of latitude near the equator, which have greater radii than the arctic parallels, the apparent excess of motion towards the west being the excess of the space described in rotation by the equinoctial above that described by the tropical and even polar circles; the velocities perpendicular to the equator, being nearly equal and contrary, produce no sensible wind, but those parallel to it produce a wind directly west and enduring, called the 'trade-wind,' with this exception, that the northern hemisphere being the warmer, the resultant is a few degrees north of the equator, crossing the Atlantic from Africa to Brazil, and the Pacific from Panama to the Philippine Isles, and the Indian seas from Sumatra to Zanguebar. But when the continents stretch into the torrid zone, the local accumulation of heat being great, two opposite periodical winds, known by the name of *monsoons*, are produced, approaching the north tropic in summer, and the south in winter, and blowing in the Arabian and Indian seas north-west from April to October, and in the contrary direction during the rest of the year: the reverse occurs south of the equator.

Now as the cold air rushes into the tropical regions, expelling the warm air of that locality between 28° on each side, the latter forms a counter-current, still possessing equatorial velocity, and produces in both hemispheres exceeding the above latitude a westerly and genial breeze, which is felt during three-quarters of the year from Newfoundland to the west of England, and from South America to the Cape of Good Hope. On the same principle the easterly, or rather north-easterly winds originate in the polar currents, and are piercingly cold in general. The great radiation of arid plains produces many local winds, such as the sirocco from Africa to Italy, and the destructive simoom of Arabia, &c., but they do not depend on general atmospheric causes.

The meteors so frequently visible in summer and in frosty weather have not yet received a satisfactory explanation, that most generally received being the existence of inflammable gases in the atmosphere: this undoubtedly is the case in the *ignis fatuus*, which, as the writer has witnessed, will change the direction of its motion by the slight current of air produced by a person walking towards it; but we are not yet able to test with great accuracy the gaseous matters which may occupy the higher regions of the atmosphere. The asteroids of November, so well described by Sir W. Herschel, have in all probability an origin independent of the atmosphere, from the regularity of their appearance about the 18th of that month, but having now become subjects of curiosity and very general observation, we may hope ere long to learn something more precise of their nature, and to take another opportunity of noticing them more at length.

Among subjects connected with meteorology which are

treated in separate articles, we may notice CLOUD, DEW, AEROLITE, AIR, BAROMETER, THERMOMETER, HYGROMETER, MIST, &c., to which articles the reader is referred.

METHODISM, a very memorable word in the English vocabulary, as the thing signified is also very memorable in the history of the Christian church, and especially of that part of it which consists of inhabitants of the British Isles.

The people of England have been described by foreign writers as being beyond all other nations *religiosissimi*, or very strongly devoted to religious thoughts and exercises. The success of Christianity on its introduction into this island is one proof of it; but still more is the great encouragement given to the religious orders and the multitude of churches which were erected in the very earliest periods. A few centuries later, we have the proof which is afforded by the great encouragement which the different orders of friars received, who were a species of Methodist preachers of the middle ages. Again, when the system of Christian instruction and edification as settled by authority was in complete operation, there were for ever arising large and powerful bodies of people who pressed for something more exciting, greater freedom, greater holiness, or greater labour in the ministers, each distinguished by its own peculiarities, but all exhibiting that part of the national character to which we have adverted, the being *religiosissimi*, being men deeply impressed with the important truths of religion, and earnest in the desire to please God, and make their own calling and election sure.

Each century seems to have had its schism arising in this national characteristic. In the fifteenth there were the *Lollards*, who were easily put down by the Church; in the sixteenth, the *Gospellers*, who, having the court with them, brought about the Reformation: in the seventeenth, the *Puritans*, who were for a short time triumphant, but who were finally reduced to the several denominations of dissenters still existing, the *Presbyterian*, the *Independent*, the *Baptist*, and the *Quakers*. In the eighteenth century, when not only the Church but the several dissenting bodies were thought by many to have lost much of the spirit and fervour of religion, there arose the *Methodists*, who, being allowed to proceed unmolested, have produced, without having attempted to overturn the Church, no small change in it, in modifying its ministrations, in calling back attention to the supposed doctrines of its founders, and in rousing its ministers to more strenuous exertions.

Methodism then designates the great English schism of the eighteenth century differing little in essence from the Puritanism of the century before. In both cases it was the desire of services of a more exciting character than were presented by ministers such as then were the ministers of the Christian religion in England, and the desire of a greater admixture of doctrinal matter in the instruction which was delivered from the pulpit. *Evangelicalism* is a kind of form of Methodism, but is perhaps sufficiently distinguished from it to be regarded as the manifestation of the extreme of religious feeling in the nineteenth century. The chief difference between Puritanism and Methodism lies in this: that the Puritans had within their body a much larger proportion of persons of rank and opulence, and that they never contemplated the attainment of their object by the introduction of an illiterate ministry. In the Methodists of the last century were found not many great, not many noble, and the instruments of the propagation of Methodism were, with very few exceptions, persons taken from the lower classes of society, men without learning or attainment, and supposed to be qualified for the work chiefly by possessing qualities which are indeed truly valuable in a Christian teacher, zeal for the promotion of holiness and virtue, and a familiarity with the letter of the Word of God. The Huntingdon family, in the female portions of it, took it under their patronage, and there were two or three other ladies of rank who attached themselves to the Countess of Huntingdon, and encouraged the labours of the Methodist preachers. But it was not till the present century that Methodism, if we may regard it as identical with Evangelicalism, obtained the countenance of many persons high in rank. This change is chiefly to be attributed to two persons, the late Mr. Wilberforce and the late Mrs. Hannah More, who were Methodists in one sense of the term, but not in the other and more common sense of it; that is, they continued in the Church pleading for greater strictness of life and greater zeal in the ministry, more energetic preaching of what they regarded the distinguishing doctrines of the gospel, and more assiduous labour in the clergy; but not, like Lady

Huntingdon, forming societies and placing pastors over them, who were to be dissenters, and not comprehended in any way within the pale of the Established Church.

It is interesting to observe the various forms in which Methodism is presented. We see it in the Church of England in the character of those ministers and congregations which are called Evangelical; we see it in a large body of dissenters now calling themselves Independent or Congregational; and we see it more strikingly in the various sects which are called the Methodist sects, and which are in fact so many different classes of persons who collectively are called Methodists. There are:—1, the Wesleyan Methodists; 2, the Methodists of Lady Huntingdon's Connection; 3, the Methodists of the New Connection; 4, the Primitive Methodists; 5, the Bible Christians; 6, Protestant Methodists; 7, Association Methodists; 8, the Inghamites. There is also a large body of persons, chiefly in Wales, calling themselves Calvinistic Methodists, who are not included in what is called Lady Huntingdon's Connection.

The year 1729 is considered as the time at which Methodism began. John Wesley, who is universally considered as the founder, was at that time residing at Oxford, being a member of that university. A brother, whose name was Charles, was residing at Oxford at the same time, and there were a few other young men who, like them, were intended for the ministry in the Church, who formed a little association for their common spiritual and religious improvement. They were soon remarked for a greater strictness of life and for wearing more of the form of religion than was then usual at Oxford. It is said that these persons very soon got the name of Methodists, arising out of a casual observation of a member of Merton College, who said, 'Here's a new sect of Methodists sprung up;' but to what set of persons in ecclesiastical or other history he referred is not quite settled. The name, it is manifest, is a very absurd one.

The Wesleys were sons of a country clergyman who resided on his living at Epworth in Lincolnshire, a part of the kingdom where at that time the inhabitants were singularly rude and uninformed. It has not been remarked by the writers of the life of Wesley that his father was educated for the ministry among the dissenters, but conformed to the Church early in life. It is not intended in this article to give a biographical notice of the founder of Methodism. This will be given in its more appropriate place. [WESLEY.] Under the word WHITEFIELD will also be found a notice of George Whitefield, another student at Oxford, who joined the Wesleys in 1732, and who had a large share with them in laying the foundation of Methodism. It may suffice for the present to say that the Wesleys and Whitefield, instead of following the usual course of clergymen, in settling down on livings, after studying in the university, undertook the wider duty of rousing their countrymen generally to a higher tone of devotional feeling, and to a regard to the doctrines of the Church, to which there was then, owing in a great measure to the writings of such men as the Latitudinarian divines originally, and, after them, of Locke, Addison, Burnet, Hoadly, Clarke, Whiston, Peirce, and others, a growing indifference: men were beginning to think that the all-in-all in Christianity was the doing justly, loving mercy, and walking humbly, looking for that blessed hope and glorious appearing of our Lord and Saviour Jesus Christ, when every man should receive according to his works. Wesley went forth proclaiming that he came to call men back to *old Church of England principles*. This was his favourite phrase, as appears by many passages in his journals, and this object (at first, at least) was what he himself considered the chief purpose of his mission. What he meant was original sin, regeneration, the atonement by the blood of Christ, the influence of the Spirit, justification by faith, freedom of the will, accountability, and eternal reward or suffering; Whitefield added to these the eternal decrees, the extreme doctrines of Calvinism.

The object of neither of them was to be founders of sects out of the Church, but to produce a change within the Church. It was soon however manifest that their end could not be attained by remaining, even outwardly, conformable to the rules of the Church in regard to its ministers. The doors of the parish churches were soon closed against them, and the meeting-houses of the dissenters were closed likewise. They then preached wherever a congregation could be gathered together, in rooms or in the open air, and preaching with the zeal and energy of Apostles, it was

in vain, with a population like the English, to attempt to prevent them from making a deep impression. Such energy of preaching had not been witnessed since the time of the old Puritans. The effect indeed may be described as marvellous. The cry, 'What shall I do to be saved?' was heard from many voices wherever they had an audience; sometimes this cry was accompanied by dreadful shriekings and faintings. The accounts given by friends and enemies are in respect of this the same. Many well-meaning persons regarded it only as a mischievous enthusiasm. By the profane the preachers were not unfrequently assaulted, and their lives placed in jeopardy. But many were soon found ready to assist them in their work, either by forming into societies persons convinced by them, and erecting chapels for their assembling together, or by taking upon themselves the office of preacher, and following in the track which their masters had trod. There were at the same time a few persons who were ministers in the Church, and who did not leave the parishes in which they were settled, who seconded the labours of these men. Such were Fletcher, Sellon, Perronett, Dickinson, Venn, Grinshaw, and others.

Whitefield died early, worn out by his extraordinary exertion. He was the founder of the Calvinistic section of Methodists. But the life of Wesley was prolonged to his eighty-seventh year; and when he died, which was in March, 1791, he had been sixty-five years in the ministry, and fifty-two years an itinerant preacher; he lived also to see in Great Britain and Ireland about three hundred itinerant preachers and a thousand of what are called local preachers 'raised up from the midst of his own people,' and eighty thousand persons in the societies under his care.

Such was the state of this one principal branch of Methodism at the time of Wesley's decease. Some thought that as it had grown with him, it would die with him; but they were mistaken. He had provided (as far as human means go) for its perpetuity by binding up his members in a church, with a frame and constitution as strong as could be given to it by subordination, authority, rules, common interest, and the bond of common property. Thoroughly regardless of accumulating personal wealth, the contributions of the members of his societies, which had long far exceeded the expenses, enabled him to transfer to the body of preachers, in whom, as in an assembly of presbyters, he vested it, whatever interest he had in a multitude of chapels in every part of England, and a large surplus fund; and this property, it is understood, has gone on year by year constantly increasing, notwithstanding the vast exertions which have been made in the erection of chapels, schools, and other buildings, the support of an additional number of preachers, and in missionary exertions among the people not yet Christianized.

It was in the year 1740 that the first Methodist society was formed. It met at a chapel in Moorfields, and it was in 1743 that the rules, which still continue in force, were drawn up for this and other societies, especially those of Bristol and Kingswood, the part of the kingdom in which, at the beginning of his ministry, Wesley had chiefly laboured. These rules set forth, that the Methodists are a people who, in addition to the form of Christianity, seek the power of godliness, and manifest it by good works: the societies are united, that by counsel, exhortation, and prayer, they may assist each other in the great work of religion.

We have next to describe the constitution of these societies and of the general union of them, forming the highly important class of Christians called the Wesleyan Methodists.

These societies are divided into classes of ten, twenty, or more persons, and he that is supposed the best qualified by mental and religious excellency, is appointed the leader. His duty is to see his members weekly, to receive the voluntary contributions of his class, and to take the amount to what is termed the 'leader's meeting,' that is, the stated meetings of all the leaders and the society stewards in a certain locality, where the society of the place is represented, and its affairs transacted. The society stewards take the monies from the leaders, pay the ministers their weekly stipend, and take the surplus to the circuit stewards at the quarterly meeting. In the leaders' meetings are stewards for the poor also, who at the direction of the meeting give to the leaders, for their poorer members, whatever funds may be furnished by any society and congregation for that purpose.

A number of these united societies lying around some cen

tral town or large chapel is known as a circuit. The villages or chapels in the vicinity of the centre are regularly visited by the ministers at stated times for the purpose of conducting worship, and the discharge of other pastoral duties. In the origin of Methodism these circuits included not merely one county, but sometimes parts of several; but now, owing to the spread of Methodism, the circuits are limited to a diameter of twenty, ten, and in some cases of fewer miles. The societies and congregations in these circuits are committed to the care of the ministers yearly appointed by the Conference; and more especially to one who is termed the superintendant; generally, when compared with his fellow-ministers in the same circuit, he is of the longest standing in the connection, but not always so, as the Conference claims the right of appointing to this office the person whom it judges the most proper. To the superintendant principally the direction of the other ministers is committed, as well as that of the local preachers also, who are men in business and only occasional preachers; and in addition to the above, the superintendant has the care of the leaders, stewards, and, in one sentence, the whole circuit: he is accountable to the Conference for the use of the power committed to him.

About the termination of every quarter, the ministers, circuit-stewards (who are two principal members in the circuit, nominated yearly by the superintendant and chosen by the quarterly meeting), society-stewards from every separate society in the circuit, and other leading friends meet, for the purpose of receiving the respective accounts of the separate societies, and the balances, if any, from the society-stewards, out of which the circuit-stewards pay the quarterly stipends of the preachers, balance all the accounts of the circuit, and determine everything within the province of the quarterly meeting, according to the Statutory Laws of Methodism, which are found in the 'Minutes of Conferences.'

A number of these circuits, as for example the collective number in any county, are united and known as a district. The Conference appoints one of the ministers therein, by ballot, as the chairman; to whose care its Methodistical direction is chiefly committed. In the month of September in every year the superintendants of the circuits in the district, and the circuit-stewards of every circuit, are called together in some central or convenient town, to arrange prospectively the financial affairs of every circuit therein, for the coming Methodistic year; that is to say, the probable amount that the connectional collections will be able to allow to every needy circuit, so that means may be taken to supply from its own resources whatever may be deficient.

In the month of May, the district, as above, is again assembled; the ministers alone the first day, to examine the moral character, Methodistical orthodoxy, and obedience of every minister therein; afterwards, in the presence of the circuit-stewards, they wind up the financial affairs of the circuit for the Methodistic year, which in May has nearly expired. The result is carefully recorded in minutes, which are authoritatively required from every chairman of every district-meeting at the next Conference.

At the May district-meeting, when the circuit-stewards have taken their departure, one of its ministers is chosen by ballot, as its general representative at the coming Conference. Then the meeting determines how many additional ministers belonging to the district shall be allowed to proceed to the Conference. The Conference, strictly and truly, consists only of one hundred preachers, whose names are in the deed that gives it a legal existence, but all the preachers allowed to go from the respective districts are suffered to sit therein, and vote as integral parts thereof. At the assembling of the Conference, one of its first acts is the choosing by ballot the president and secretary, who must be of the hundred, the legal Conference. The business which follows comprises the supplying of the places of those who by death, &c., have been removed, by the hundred, partly by ballot and partly by nomination; the examination of the character of every minister as to his moral conduct, Methodistical orthodoxy, &c.; the examination of the minutes of the several districts; the appointments of the ministers for the coming year. Further, they legislate for and determine the multifarious concerns of the connection.

In Methodism, the members are divided into two great classes, the ministers and the people; and each, if accused, is tried at its separate tribunal, and by its own peers. The members are tried by the leaders' meeting; and the ministers by the ministers only, at a district-meeting. If either the mem-

bers or ministers are dissatisfied with the decision of their respective judicatories, they may appeal to the Conference the highest court of Methodism.

Methodism furnishes its ministers from the members, who first are known as local preachers, and then nominated at the March quarterly meeting as persons proper to be recommended for examination at the coming May district-meeting by the ministers alone. If the churches in the circuit, by their representatives at the quarterly meeting, recommend the person nominated, he appears before the district-meeting and undergoes an examination as to his personal acquaintance with Christianity, his Methodistic orthodoxy, and attachment to its discipline. If approved and recommended by the district-meeting, his name is brought before the next Conference. If all inquiries here are satisfactorily met, he is either immediately employed as a probationer, in which state he must continue for four years, before he can be admitted into full connection, that is, be ordained and permitted to administer the sacraments, or he may be placed on the list of reserve, and if approved, when again examined by the preachers in the London district, he will be admitted to the Theological Institution, and by training for some two or three years, be prepared for his work.

The doctrinal test of the Methodists is found in certain volumes of Mr. Wesley's Sermons, and his notes on the New Testament. Among the most prominent of these doctrines, next to the being of God, his perfections, and worship, are—original sin, moral impotency, the sufficiency of grace, the atonement, general redemption, justification by faith, the witness and work of the Spirit, entire regeneration, good works as the fruits thereof, eternal life, and everlasting punishment.

The disciplinary test is found in the minutes of Conferences, the statute-books of the Wesleyans. While the ministers appointed by the Conference keep within the above limits, they have a right to the pulpits, and are beyond control. But any departure from the above will give authority to the trustees of any chapel in which un-Methodistical doctrine is preached, to require the chairman of that district to summon the ministers of the district, and the trustees of the circuit in which the supposed transgressor is found, and if at the district meeting so constituted his delinquency is proved, he may be suspended until the next Conference, when the whole case will be reviewed, and finally adjudicated.

While the ministers are irreproachable, the Conference claims the right of appointing them to all the chapels in the connection settled on the Conference plan, and this right is beyond dispute or control; but over the property of the chapels the Conference has no control, except it be the giving or withholding permission to the trustees to sell, when this is craved by them.

The labours of Wesley had not been wholly confined to England. He had made little impression upon Scotland, where the number of members at the time of his decease scarcely exceeded a thousand. But in Ireland he had about fifteen thousand, and in the United States there were about thirty thousand. Since his decease, the prevalence of Wesleyan Methodism in North America has been very great, the number of members reported at the Conference of 1838 being 658,574 under the care of the American conference; and 14,000 under the care of the Wesleyan Methodist church in Upper Canada.

The following table will show the progress made by them in England:—

Year.	Circuits.	Preachers.	Supernumeraries.	Members.
1767	27	76	1	22,642
1777	43	118	—	32,290
1787	69	176	10	49,946
1797	106	272	9	81,451
1807	170	431	37	117,054
1817	297	644	48	190,323
1827	331	715	77	233,581

The number of Scotch members, in 1827, was 3658. In 1838 the number of members in Great Britain was 296,801, which is not half the number reckoned in the United States of America.

The Wesleyan Methodists have established foreign missions at Stockholm; in Germany, France, Gibraltar, and Malta; in Hindustan and Ceylon; in New South Wales, Van Diemen's Land, Newfoundland, and the Friendly Islands; in Africa, in the West Indies, and in British North America. The number of persons reported to the last Con-

ference (1838) as under the care of their foreign missionaries in their various stations was 66,808.

This is to be regarded as the state of only one branch of Methodism, a principal branch undoubtedly, or rather the main branch, but there are the several branches besides of which we have already spoken, each with chapels, preachers, and numerous members, and most of them having some special missionary service for the extension of the knowledge of Christ's Holy Gospel.

Some of them have separated from the main body of Methodists since the death of Mr. Wesley. The respect paid to him has not been so generally transferred to the hundred ministers, in whom he vested the power of managing the affairs of his community, as he probably wished and expected.

In 1793 great dissensions existed about the sacraments, whether they should or should not be administered by the ministers, in the chapels, to the members of the society who required them as a part of Christianity. This led to secessions at Bristol and elsewhere. In 1795 many influential societies chose delegates, and sent them to the Conference then held at Manchester, for the purpose of claiming some share in the government of Methodism. This led to concessions as they may be found in the Plan of Pacification,—the Bill of Rights of the Methodists.

With these concessions many were not satisfied, and, being led principally by the Rev. Alexander Kilham, they seceded and formed the New Connection, a truly respectable body. Mr. Bryant, of the North Cornwall district, was the founder of the Bible Christian Methodists. The Primitive Methodists, who are sometimes known as Ranters, originated in Staffordshire: their professed object is to recall the Wesleyans to the antient spirit and fervor with which their fathers met rude and uncivilised mobs. Dissension in Leeds some ten years since gave birth to the Protestant Methodists, who declared that the Wesleyans had violated their own laws by the erection of an organ in one of the chapels in that town, contrary to the decision of a leaders' meeting. Some four years since, the establishment of the Theological Institution, the expulsion of Dr. Samuel Warren, and contentions on the rights of leaders' meetings, gave existence to the Association Methodists. These are the leading offshoots from the Wesleyan body.

The reader who wishes to see how Methodism appears to a person of an acute and discerning mind, who is not of the body, may consult the 'Life of Wesley,' by Robert Southey, a work in which there is much profound reflection. The work has however found little favour in the eyes of the Methodists themselves; and one of their ministers, the Rev. Richard Watson, has published Observations upon it, in which Dr. Southey is rather severely handled. Other Lives of Wesley there are by Hampson, by Dr. Coke, Dr. Whitehead, Henry Moore, and by the same Mr. Watson. Dr. Adam Clark's 'Memoirs of the Wesley family' is but a poor and tasteless performance. We may mention also a little volume entitled 'A Miniature of Methodism, or a Brief Account of the History, Doctrines, Discipline, and Character of the Methodists,' by Valentine Ward, of which the sixth edition was published in 1834. There is also 'The Portraiture of Methodism,' by Joseph Nightingale, and many histories of the rise and progress of Methodism in particular districts. Those who wish thoroughly to understand Methodism in its genius and true character, to see its defects and its excellences, the difficulties with which it had to contend, and the means by which it triumphed, would do well to read the 'Journal of John Wesley,' published by himself, a piece of autobiography worthy the attention of all, but especially of the philosophic observer of the actions of mankind when under the influence of strong religious excitement, or of an individual, when under a sense of duty, or by whatever impulse, he emancipates himself from those restraints which society has endeavoured to impose (though such endeavours are but vain) upon private judgment in affairs relating to religion, and private religious thought and action.

METHODIUS and CYRILLUS, two brothers, the apostles of Christianity among the Slavonians in the eighth century, and the inventors of the Slavonian alphabet, were natives of Salonica or Thessalonica in Greece. Methodius held a high command in the Greek army under the emperor Michael III. Constantine, or according to the monastic name he afterwards assumed, Cyrillus, who had been educated at the court of Constantinople, was in holy orders, and

was keeper of the library of Santa Sophia. He was first sent by the emperor as a missionary to convert the Saracens inhabiting the banks of the Euphrates; and about the year 863 he and his brother Methodius proceeded on a religious mission to the Slavonians, at the request of the princes Rotislav, Swiatopolk, and Kozel, who had made application to the court of Constantinople for instructors in the Christian faith. The choice both of the emperor and the clergy fell upon Methodius and Cyrillus, the first being selected on account of his knowledge of the Slavonian, and the other because he was well skilled in many Oriental languages. Whether both brothers had a share in the formation of the Slavonian alphabet is doubtful, some writers attributing it to both of them, others to only one, and of these latter some to Methodius, others again to Cyrillus. They translated the Psalter, the Gospels, and many other parts of the Scriptures into Slavonic. Cyrillus however did not continue there above four years and a half, after which he visited Bulgaria, and next proceeded to Rome, where he died, according to Schlozer in 871; according to others, in 873. Methodius, on the contrary, remained, and continued his labours for about thirty years, in the course of which time he is said to have translated all the Scriptures. None of the original manuscripts are extant, but it is supposed that the Slavonic version adopted by the Greek church is derived immediately from that of Methodius and Cyrillus.

METHO'NE, MODON. [MESSENIA.]

METIUS, ADRIAN, was born at Alkmaar, a town of North Holland, 9th of December, 1571. His father, whose name, according to Lalonde, was likewise Adrian, although Montucla calls him Peter, was a military engineer of considerable reputation. His skill contributed greatly to the successful defence of Alkmaar, when besieged by the Spaniards in 1573. It was he also, and not his son, who first gave 355:113 as the ratio of the circumference of the circle to its diameter.

From his father young Adrian soon acquired a practical knowledge of the mathematics, which his natural inclinations towards such pursuits enabled him greatly to improve. After studying law and medicine at the university of Franeker, he passed into Germany and Denmark, where he became a pupil of Tycho Brahe. Upon his return to Holland he assisted his father in his professional avocations, until the year 1598, when he was appointed professor of mathematics in the university of Franeker. He retained this appointment until his death, which took place at Franeker, 26th of September, 1635. A considerable part of his fortune was expended in the study of alchemy, but he either ridiculed or disregarded the speculations of astrologers. The following list of his works is given by his friend P. Winsem, in his 'Elogium Adriani Metii,' printed in the 'Memoirs of the Academy of Franeker':—'*Doctrina Sphærica*,' Francq., 1598, 8vo.; '*Institutionum Astronomicarum Libri III.*' Ibid., 1606, 1608, 8vo.; '*Arithmetica et Geometria Practica*,' Ibid., 1611, 4to.; '*De Gemino Usu utriusque Globi*,' Amst., 1611, 4to.; '*Praxis nova Geometrica per usum circini et regulæ proportionalis*,' Francq., 1623, 4to.; '*Calendarium perpetuum articulis Digtorum computandum*,' Roterod., 1627, 8vo.; '*Astrolabium*,' Francq., 1627, 4to.; '*Opera omnia Astronomica*,' Amst., 1633, 4to.

(*Biographie Universelle*; Montucla, *Histoire des Mathém.*; Hutton's *Dictionary*.)

METIUS, JAMES, was a younger brother of the preceding, and the reputed inventor of the refracting telescope. On this point Montucla quotes the following passage from the '*Dioptrics*' of Descartes, wherein the latter says, 'It is now about thirty years since this admirable invention was first ascribed to James Metius, a man who had never studied the mathematics, notwithstanding that both his father and brother had made them their profession. This individual, while one day amusing himself with a few burning-glasses, after looking through them singly, began to look through them by pairs, placing one at each extremity of a short tube. In this way a convex and concave lens happening to be employed together, the first refracting telescope is said to have been constructed.' (Montucla, tom. ii., p. 230.) The reputed date of this discovery is the beginning of the seventeenth century.

A somewhat similar story is related of the children of a spectacle-maker of Middelburg, in Zealand. There is however as much or more reason to suppose that the discovery took place in England, more particularly when it is remembered that the satellites of Jupiter were observed in

England by Harriot in 1610. (See the 'History of Optics,' by Mr. Barlow, in the *Encyclopædia Metropolitana*.) Weiss adds (*Biog. Univers.*) that Metius guarded his secret with such extreme caution, that, even when about to die, the priest who attended him could not induce him to divulge it; another story is that he confided the secret reluctantly to Prince Maurice, on an occasion when that prince honoured him with a visit for that especial purpose. We have not been able to find the year in which James Metius was born, or that in which he died.

METON, METONIC CYCLE. The astronomer Meton was living at Athens at the beginning of the 87th Olympiad, B.C. 432. He was, according to some, a Lacedæmonian (Λάκων), but the best authorities call him a Leuconian (Λευκονεύς). All we know which is worth recording here is, that the solstices which he observed with Euctemon are preserved by Ptolemy, and that he was the founder of the celebrated lunar cycle which is still preserved by the Western churches in their computation of Easter.

The Metonic cycle takes its rise as follows: 235 revolutions of the moon are very nearly 19 revolutions of the sun, and one complete revolution of the moon's node. If these approximations were exact, all the relative phenomena of the sun and moon, particularly those of eclipses, would recommence in the same order, at the end of every nineteen years. There is however an error of some hours in every cycle. [CALIPPUS; MOON; PERIOD OF REVOLUTION.]

The first year of the first Metonic period commenced with the summer solstice of the year 432 B.C.; and if the reckoning had been continuous, what is now called the *golden number* of any year would have denoted the year of the Metonic cycle, if the summer solstice had continued to be the commencement of the year. On reckoning however it will be found that A.D. 1, which is made the first year of a period of 19 years, would have been part of the fourteenth and part of the fifteenth of a Metonic cycle.

METOPE. [BASSO RILIEVO]

METOPIA (Ornithology), Mr. Swainson's name for a subgenus of *Pipra*.

METRE (from the Greek μέτρον, *metron*) is that quality of verse by which it is to the ear distinguishable from prose. It is generally held to be one of the essentials of poetry; imaginative thought being the other. No reason can be assigned for this opinion, the truth being that it is attributable only to our nature as men, by which we feel pleasure in rhythmical arrangement of words, and consistently with which we cannot consider imaginative writing as perfect, unless couched in metre.

A distinction has been drawn between antient and modern metres, one being said to depend on quantity, the other on accent; quantity and accent being further supposed to differ in kind. A little reflection however will tend to convince us that delicacy of ear has as much to do with the difference between antient and modern metres as any fancied change from quantity into accent.

The southern nations still retain this delicacy of ear, as we know from the marked difference in Italian between the pronunciation of double and single consonants, a difference to which our language is a stranger as far as *time* is concerned. Though we see no distinction in time between the second syllable of the words *laborare* and *liberare*, there is no reason why the Romans should not, and with that assumption the whole difference between accent and quantity vanishes. It would be useless to enumerate the names which have been given to metres. The Greek and Roman metres differ from our own in being more numerous, and in allowing collocations of syllables (called feet) such as we could scarcely feel to be consonant with rhythm. The cause of this difference seems to lie in the form of each language.

Another grand distinction between antient and modern metres is that of rhyme, which occurs but seldom in the former, and which, until the time of Shakspeare, was nearly universal in the latter. Antient and modern languages both afford specimens of the alliterative measure. It may be traced in the older Latin writers, and was the distinguishing peculiarity of the Anglo-Saxon verse. 'Piers Plouman's Visions' are the best known compositions of this kind. Those who seek for further information on the subject of English metres, particularly on peculiarities which have occasioned so much difficulty to the readers of Chaucer, will do well to consult Mr. Guest's 'History of

English Metres.' Some observations by Coleridge, prefixed to 'Christabel,' are also worth attention.

METRIORHYNCHUS, Dr. Hermann von Meyer's name for a genus of fossil *Gavials*, found, according to him, in the lias, the Oxford clay, at Honfleur, and the Kimmeridge clay at Havre.

Example, *Metriorhynchus Geoffroyi* (H. von Meyer); 2nd, *Gavial de Honfleur*, Cuv., 'Oss. Foss.' v., pl. 2, pp. 143 and 525; *Steneosaurus rostro-minor*, Geoff.

METRONOME (from μέτρον, *measure*, and νόμος, *a division*; also, *a song*), a very ingenious instrument, a pendulum, the point of suspension of which is between the extremities, invented, and introduced about the year 1814, by John Maelzel (civil engineer, and mechanician to the emperor of Austria), for the purpose of determining the movement, i.e. the quickness or slowness of musical compositions.

Of the utility of a *time-measurer*, both to composers and performers, and for some account of its early use, see CHRONOMETER.

Of Maelzel's Metronome there are two kinds. The one is a pendulum kept in motion by a spring and wheelwork, and which ticks the vibrations:—the other is also a pendulum, as above described, but without any machinery, and acting only so long as the force of the impulse given shall last. The former, therefore, it will be obvious, is complicated and expensive; the latter is simple and cheap.

The inventor thus describes and explains the manner of using this instrument:—

'1. A sliding weight is attached to the rod (which is graduated) or steel pendulum; the higher up this weight is shifted, the slower will be the vibrations, and *vice versa*; so that when the weight corresponds with the number 50, the vibrations will be the slowest possible; at No. 160 they will be the quickest.

'2. These numbers have all reference to a *minute of time*; i.e. when the weight is placed at 50, fifty beats or ticks will occur in each minute; when at 60, 60 beats, or seconds exactly, in a minute; when at 100, 100 beats in a minute, &c.; any stop-watch, therefore, will show how far the correctness of the metronome may be depended on.

'3. The doubles of the numbers of the scale answer to a precisely *double* degree of velocity. Thus, if 50 be the proper number for a minim, 100 will be the number for the crotchet in the same movement, &c. The numbers omitted on the scale have been found practically unnecessary.

'4. The composer is best able to judge, from the nature of his movement, whether to mark its time by minims, crotchets, quavers, &c. Generally speaking it will be found, that in *adagios* it is most convenient to mark the time on the Metronome by quavers; in *andantes* by crotchets; in *allegros* by minims, and in *prestos* by whole bars. As often however as the case may admit, it is desirable that the pendulum should be made to beat integral parts of a bar, just as a master would beat or count the time.'

Much opposition was made to the use of this excellent instrument, when first introduced; but no sensible composer or performer now entertains a doubt of the usefulness of the Metronome, or of some kind of pendulum answering the same purpose.

METRO'POLIS. [COLONY, vol. vii., p. 359.]

METZ, a city in France, capital of the department of Moselle, situated on the Moselle at the junction of the Seille; 172 miles in a direct line east by north of Paris, or 191 miles by the road through Château-Thierry, Châlons-sur-Marne, and Verdun; in 49° 6' N. lat. and 6° 12' E. longitude.

This city existed in the time of the Romans, to whom it was known by the name Divodurum, and was the chief town of the Mediomatrici, one of the Belgic nations. At a later date it took the name of the nation, Mediomatrici, for which, early in the fifth century, was substituted the shorter designation of Mettis or Metis, whence the modern Metz. In the civil dissensions which followed the death of Nero, A.D. 70, Divodurum was nearly destroyed by a sudden outbreak of the troops of Vitellius. (Tacit., *Histor.*, i. 63.) Divodurum was ruined in the invasion of the Huns under Attila, A.D. 452; but afterwards became the capital of Austrasia, which was sometimes termed the kingdom of Metz.

In the division of the Carolingian empire, Metz was comprehended in the kingdom of Lotharingia or Lorraine.

[**LORRAINE.**] The grants of the emperors to the bishops of Metz, Toul, and Verdun, rendered those prelates feudal lords of their respective dioceses, subject only to the supremacy of the emperor; and this part of Lorraine became known in history as *Les Trois Evêchés*, 'the three bishoprics.' The city of Metz was however made, by the emperor Otho II., a free Imperial city, with a voice in the diet of the empire, the right of choosing its own magistrates, and of coining money. The city became exceedingly flourishing, being the centre, apparently, of a great inland trade between France and Germany; and in A.D. 1444 was enabled to resist an attack from the combined forces of Charles VII. of France, and René of Anjou, king of Sicily and duke of Lorraine. The attempts to check the progress of the Reformation appear to have occasioned some troubles at Metz; but the principles of the reformers made such progress, that A.D. 1543 they were allowed the free exercise of worship. In the troubles of the empire near the close of the reign of Charles V., Henri II. of France, with whom the German Protestant princes had formed an alliance, entered Lorraine with an army, and was admitted into Metz by the townsmen, A.D. 1552. In the same year the emperor besieged the place with 100,000 men; but the duke of Guise, who commanded the garrison, made so stout a defence, that the emperor was obliged, in Jan., 1553, to raise the siege. From this time the town remained under the protection of France, though the bishops recognised the authority of the emperors, and received their investiture from them. This arrangement lasted until 1633, when the king of France assumed the sovereignty of *Les Trois Evêchés*, which was confirmed to him by the treaty of Münster, or Westphalia, A.D. 1648. The siege of the town, subsequent dissensions, and the loss of its municipal freedom, caused a decay of trade and population; and at the close of the seventeenth century, the town numbered only 22,000 inhabitants.

In the division of France before the Revolution, Metz, with the rest of *Les Trois Evêchés*, was included in the province or military government of Lorraine.

The Moselle and the Seille are divided in and near the town into several channels, enclosing small islands, on some of which, as well as on the mainland, the town is built. Metz is a fortress of the first class. [**HORN WORK.**]

There are nine gates with drawbridges. The interior of the town, which is principally in the angle formed by the two rivers, is in general handsome. The streets are wide, straight, and well paved. The square called 'Quartier Coislin,' in the south part of the town, is very handsome, and the esplanade of the citadel affords a pleasant promenade. The square of St. Louis is surrounded with arcades. The houses are for the most part well built. The cathedral is a Gothic building, remarkable for the boldness and lightness of its architecture: its length is estimated at 363 feet (probably French feet, equal to about 387 English feet), and the height of the tower at 373 French, 398 English feet. There are nine other churches, four nunneries, a consistorial Protestant church, and a Jews' synagogue. The Jews had formerly a particular quarter of the town assigned to them, which is still distinguished by its dirty and narrow streets. The most remarkable of the churches are those of St. Simon, Notre Dame, and St. Vincent, the last distinguished by a portal with a triple row of columns. The town-hall, the Palais du Gouvernement, built at a great expense in the reign of Louis XVI., where the courts of law sit, the prefect's office, the theatre, a building of greater external than internal beauty (these two last-named edifices are on an island of the Moselle), the royal college or high school, the military hospital, a vast building, the arsenal, the different barracks, the building for the school and staff of the artillery, the workhouse, and the covered market, lately erected,—are among the public buildings most worthy of notice. There are twenty bridges, ten over the arms of the Moselle, and as many over those of the Seille.

The population of the town has been gradually increasing since the commencement of the eighteenth century. In 1741 it was 30,000; in 1789, 36,000; in 1800, 32,000; in 1814, 41,000; in 1831, 44,416; in 1836, 42,793. The chief branches of manufacture are woollen cloths, flannels, and stuffs, cotton yarn, leather (formerly the staple of the place, diminished by the continuance of war, but now reviving), hats, especially military hats, braid trimmings, and embroidery (in which 1200 people are employed), starch, soap, beer (which is very good), brushes, pencils, iron wares, cutlery, buttons, jewellery, clocks, paper-hangings, and

P. C., No. 930.

confectionary. There are workshops connected with the arsenal and other military establishments. In the neighbourhood of the town are quarries of good limestone, tile-kilns, beet-root sugar-houses, and other industrial establishments. Trade is carried on by means of the Moselle, which is navigable to Nancy, many miles above Metz. High roads communicate with Luxembourg, Namur, and other places in Belgium; with Mainz and Frankfort in Germany; and with Strasbourg, Nancy, and Paris.

Metz is the seat of a bishop's see, the diocese of which comprehends the department of Moselle, and the bishop of which is a suffragan of the archbishop of Besançon. It has a Cour Royale and an Académie Universitaire, the jurisdiction of which embraces the departments of Ardennes and Moselle. Here also are the head-quarters of the third military division, including the departments of Moselle, Meurthe, and Vosges. There are a variety of other government offices, fiscal, judicial, and administrative. There are also a number of establishments connected with the military department, a royal practical school of artillery and military engineering (the finest institution of the kind in Europe), regimental schools of artillery and engineering, a central military pyrotechnic school, and a miners' school. For general or special instruction there are the faculties connected with the Académie Universitaire; a college or high school, a normal school, a society of literature, science, and art; a society for the encouragement of agriculture and of industry; a philharmonic society, free courses of instruction or schools for drawing, painting, music, and geometry and mechanics applied to the arts; public lectures on midwifery and botany, a school of trade, a society for the encouragement of elementary instruction, a departmental society for medical science, a society for the encouragement of arts and trades, maintained by the wealthier Jews (of which nation there are many at Metz) for their poorer brethren; a maternity society, and a mont de piété, or loan society; a public library of 31,000 volumes, three other libraries, a botanic garden, a departmental nursery ground, and museums of natural history and mineralogy. There is a school or schools taught by the Frères de la Doctrine Chrétienne, with a thousand pupils.

The arrondissement of Metz comprehends an area of 620 square miles: it is divided into nine cantons or districts, each under a justice of the peace, and comprehends 218 communes. Its population in 1831 was 150,840; in 1836, 150,811.

In the neighbourhood of the town are the remains of a Roman aqueduct, which conducted the waters of a stream, seven or eight miles distant, to the Naumachia, which was in the south part of the town. Seventeen arches of this aqueduct yet remain. The ruins of an amphitheatre and of a Roman palace have been also discovered.

The territory known as Le Pays Messin comprehended the territory immediately around the city, included in the diocese and jurisdiction of the bishops, to which alone the name was in strictness applicable, and the lordships scattered through Lorraine, which formed part of the temporalities of the see. The former is entirely and the latter are partly comprehended in the department of Moselle; some of the lordships are in the departments of Meurthe and Vosges.

MEUDON. [**SEINE ET OISE.**]

MEULAN. [**SEINE ET OISE.**]

MEULEN, ANTHONY FRANCIS VAN DER, born at Brussels in 1634, was a disciple of Peter Sneyers, an eminent battle-painter, under whom he improved with extraordinary rapidity. While he was pursuing his profession at Brussels, it happened that some of his works were taken to Paris, and shown to the minister Colbert, who was so pleased with them that he invited him to Paris on very honourable and advantageous conditions. His talents as a battle-painter recommended him to Louis XIV., whom he always accompanied in his campaigns. He designed on the spot the most remarkable events, and the views of the cities and fortresses which had been the scene of the most memorable victories, and from these sketches he composed the paintings which were to perpetuate the remembrance of the king's successes. Such opportunities enabled him to attain that perfection in his art, of which his numerous works give such evidence. They are distinguished by truth to nature, excellent colouring, freedom of touch, and the happiest distribution of light and shade. No painter excelled him in designing the motions and attitudes

VOL. XV.—U

of norses; and this induced his friend Le Brun, whose niece he married, to give to him the execution of the horses in his celebrated paintings of the battles of Alexander the Great. Van der Meulen painted also landscapes, and other subjects, with equal excellence. His principal works are at Paris; but many of his easel pictures are preserved in England, France, and Flanders. In the 16th and 18th vols. of the *Cabinet du Roi*, there are 152 engravings after his works. He was chosen member of the French Academy of Painting in 1673. He died in 1690, at the age of 56 years. His most celebrated scholar was I. Van Huchtenburg, battle-painter to Prince Eugene.

MEUN. [LOIRET.]

MEURSIUS, JOHN (the Latinized form of his real name, which was De Meurs), was born near the Hague, in 1579. He was educated at the university of Leyden; and after he had completed his studies, was entrusted with the education of the children of Barneveldt. [BARNEVELDT.] In 1610, Meursius was appointed professor of history at Leyden, and in the year following professor of Greek. After the execution of Barneveldt, on the 14th of May, 1619, Meursius was exposed to great annoyance and persecution from the enemies of his illustrious patron; and it was therefore with great pleasure that he accepted an invitation from the king of Denmark, in 1625, to settle in his dominions. Meursius died on the 20th of September, 1639.

Meursius was a diligent and laborious scholar. He edited several Latin and Greek writers, and wrote many works on historical and archæological subjects, which were collected and published by Lami, Florence, 1741-63, 12 vols. folio. The following are a few of his principal works:—1, 'Glossarium Græco-barbarum,' Loyd., 1614. 2, Various treatises on different branches of Greek and Roman antiquities, most of which are reprinted in the 'Thesaurus' of Grævius. 3, 'Rerum Belgicarum Liber Primus,' Leyden, 1612. 4, 'Historia Danica,' Copenhagen, 1630.

MEURTHE, a department in the north-east of France, bounded on the north by that of Moselle, on the north-east and east by that of Bas Rhin, on the south-east and south by that of Vosges, and on the west by that of Meuse. Its form is compact; the greatest length is from east to west, from the neighbourhood of Phalsbourg to that of Commercy (Meuse), 70 to 71 miles; its greatest breadth, at right angles to the length, is from the bank of the Moselle, between Pont-a-Mousson and Metz, to the neighbourhood of Mirecourt (Vosges), 46 miles. Its area is estimated at 2357 square miles, which is nearly the average extent of the French departments, and rather greater than the conjoint areas of the English counties of Kent and Surrey. The population in 1831 was 415,568, in 1836 it was 424,366, showing an increase in five years of 8798, or above 2 per cent., and giving 180 inhabitants to a square mile. Both in amount and density of population it considerably exceeds the average of the departments, but falls considerably short of the average density of population in England. Nancy, or Nanci, the capital, is in 48° 41' N. lat., 6° 11' E. long., 172 miles in a direct line east of Paris, or 204 miles by the road through Château-Thierry, Châlons-sur-Marne, Vitry-sur-Marne, Bar-le-Duc, and Toul.

The department is hilly, and even mountainous. The principal chain of the Vosges crosses the eastern extremity between Sarrebourg and Phalsbourg; and branches from this mountain chain, of gradually diminishing height, extend over the eastern portion of the department. Near the principal chain of the Vosges the mountains are intersected by narrow valleys, which frequently present picturesque scenery. Amid the lower slopes are several lakes, as those of Lindre, Stock, &c.; there are also several marshes. The western side of the department is traversed by the hills which bound on the east side the narrow valley of the Meuse, and separate it from that of the Moselle. Between these hills and the Vosges is the valley of the Moselle. The Vosges in this department are composed chiefly of the new red or saliferous sandstone and the subjacent secondary rocks; the rest of the department is occupied by the rocks which intervene between the chalk and the red sandstone. The mineral treasures of the department comprehend freestone for building, and limestone, which are quarried in numerous places; gypsum is also abundant, and good marble is quarried near Nancy. Various ores of iron are found, but not in sufficient quantity to make it worth while to extract them. There are two forges for producing wrought-iron. The most important mineral is

rock-salt, of which a vast bed was discovered in 1819, within a mile of the town of Vic on the Seille, at a distance of rather more than 200 feet below the surface. In penetrating about 100 feet lower, five strata of rock-salt were found, having an aggregate thickness of nearly 90 feet, separated from each other by thin strata of gypsum or clay. A sixth stratum has been discovered a few feet below the others: these strata have been ascertained to have a superficial extent of 230 square miles. The salt is pure muriate of soda. The working of the mine commenced in 1823. The cost of raising the salt and breaking it small is very trifling, about 8s. to 8s. 6d. per ton. The department has long been known for its brine springs, which have been estimated to produce yearly 41,000 to 42,000 tons: the principal springs are in the valley of the Seille at Dieuze, Château Salins, and Moyenvic; there are some in the valley of the Moselle, as that of Mousson near Pont-a-Mousson, and of St. Thiébault near Nancy. The cost of refining this salt is nearly double that of preparing the rock-salt.

The department belongs almost entirely to the basin of the Moselle: a small portion at the eastern extremity, which passes over the principal ridge of the Vosges, is included in the basin of the Rhine, of which indeed that of the Moselle is only a subdivision, and another small portion on the south-western border is included in the basin of the Meuse.

The Moselle enters the department on the south side, a little below the town of Charmes (Vosges), and flows north-west in a rather circuitous channel to Toul; at Toul it turns to the north-east, and flows in a circuitous channel to the junction of the Meurthe, from which point it flows north by west into the department of Moselle. Its whole course in the department may be estimated at 65 miles, for 18 of which (22 according to the government statement), viz. from the junction of the Meurthe, it is navigable.

The principal tributary of the Moselle in this department is the Meurthe. This stream, which rises in the western slope of the Vosges, several miles south-east of St. Dié (Vosges), and has a north-west course, enters this department just below the town of Raon l'Étape (Vosges), and flows north-west to Lunéville, where it receives the Vezouze on the right bank, and a mile or two lower down the Mortagne on the left. Below Lunéville the river makes a bend, but after passing the town of Rosières, and receiving the little river Sanon, it resumes its north-western course, and flows past Nancy into the Moselle. Its whole course may be estimated at 75 miles, of which nearly 50 are in this department; the navigation, which commences at Nancy, is of seven miles. It is used for floating timber from the neighbourhood of its source, and a considerable quantity of deals and firewood are sent down by it. It is subject to frequent inundations from the melting of the snow or the falling of heavy rains in the mountains where it rises.

The Madon, another considerable feeder of the Moselle, enters this department on the south side, and flows into the Moselle above Toul. Its source is in the heights south-west of Epinal (Vosges), and its whole course is above 40 miles, about 16 of which are in this department. It receives the little river Uory. The Math, a small stream, waters the north-west part of the department, and joins the Moselle just within the border. The Seille, a more considerable stream, waters the northern side of the department, and receives the Verbach and the Petite Seille; it joins the Moselle at Metz, in the adjacent department of Moselle. The Sarre, another and more important feeder of the Moselle, rises in the Vosges and waters the east side of the department, a few miles beyond which it becomes navigable. The Zorn, which rises just within the eastern boundary, flows into the Rhine; and the Deuil, which waters the south-western border, belongs to the system of the Meuse. There is one navigable canal, that of Les Salines de l'Est (the Eastern Salt-works), 22 to 23 miles long. It commences at the little town of Dieuze, on the Seille, and runs north-east into the Sarre at Sarrealbo (Moselle); only a part of it is in this department.

The department has eight Routes Royales, or government roads, the aggregate length of which (on January 1, 1837) was 261 miles, viz. 223 in repair and 38 out of repair. The principal road is that from Paris to Nancy and Strasbourg, which enters the department on the west side, and runs by Toul to Nancy, from whence it is continued, first along the valley of the Meurthe to Lunéville, and then along that of

the Vezouze to Blamont, from which town it runs north-east across the Vosges by Sarrebourg and Phalsbourg into the department of Bas Rhin. Another road branching off from this at Nancy, and rejoining it at Sarrebourg, runs through Château Salins and Moyenvic. Roads run from Nancy along the valley of the Moselle, downward to Pont-à-Mousson and Metz (Moselle), and upward to Charmes and Epinal (Vosges), and across the Moselle and the Meuse to Neufchâteau (Vosges) and Langres (Haute Marne). Roads lead from Château Salins, one to Metz, and another to Sarreguemines (Moselle); from Pont-à-Mousson to Commercy (Meuse) and Bar-le-Duc (Meuse), and from Lunéville to St. Dié (Vosges) and Colmar (Haut Rhin). The aggregate length of the Routes Départementales was (January 1, 1837) about 233 miles, viz. 168 in good repair, 42 out of repair, and 23 unfinished. The bye-roads and paths had an aggregate length of 3000 miles.

The climate of the department is colder than the latitude would lead us to suppose, a circumstance which is ascribed to the elevation of the eastern parts, the quantity of woodland, and the extent of water. The air is in most parts tolerably healthy. In the neighbourhood of the Vosges however the inhabitants of the valleys are very subject to putrid fevers. Intermittent fevers are prevalent in some districts, and in others the inhabitants are afflicted with large goitres, with scurvy or rupture.

About 760,000 acres, half the soil of the department, is under the plough; it is of various degrees of fertility, but the produce in grain is on the whole very far above the average of France; in wheat, which is the grain chiefly cultivated, the produce is twice the average; and in oats, which are cultivated to nearly or quite the same extent as wheat, the produce is nearly three times the average. In barley the produce is about equal to the average of France; of rye and maslin, or mixed corn, a comparatively small quantity is raised; and of maize and buckwheat scarcely any. Potatoes are cultivated very extensively.

Besides corn and potatoes, a considerable quantity of rape, colza, &c., for oil is grown; also flax, hemp, chicory, and pulse. A few hops are grown. The cultivation of the vine has much increased of late years. The vineyards now occupy above 40,000 acres, which is below the average of the departments, but the produce in wine is considerably above the average. The wine is for the most part thin and poor; some of the growths, as the red wines of Pagny-sous-Preny, Thiaucourt, Arnaville, Baudonville, Neuville, and Vic, are agreeable and delicate. About 16,000 acres are laid out in orchards, gardens, and nursery-grounds. The fruit-trees are generally trained as espaliers. The stone-fruits are chiefly cultivated, particularly an oval plum of excellent flavour, called the Coëche, of which great quantities are dried. The apricots of Nancy are in good repute. The quantity of woodland is about 280,000 acres; the abundance of fuel is a great advantage to the various manufactures of the department.

There are about 180,000 acres of meadow land, and about 15,000 acres of heath or common. The number of horned cattle is on the whole rather below the average of France. The quantity of cheese and butter made in the department is not equal to the consumption. Sheep are not numerous, and are of a large coarse-wooled breed. Horses are numerous but small. The antient dukes of Lorraine had done much to improve the breed by importing stallions from the Levant; they have however been suffered to degenerate. Horses are chiefly used for agricultural labour.

Poultry is abundant; but there are few bees. Wolves and foxes are numerous in the woods; there are also some wild boars, roebucks, and smaller game. Rats, mice, field-mice, and moles commit considerable devastations, and caterpillars are numerous and destructive.

The department is divided into five arrondissements, as follows:—

	Area in sq. miles.	Population. 1831.	Population. 1836.	Com- munes.
Nancy, central	551	127,944	129,841	187
Château Salins, north	418	69,810	70,287	147
Lunéville, south	468	82,851	84,698	145
Sarrebourg, east	461	72,546	75,499	116
Toul, west	459	62,417	64,041	119
	2337	416,568	424,366	714

There are 29 cantons, or districts, each under a justice of the peace.

In the arrondissement of Nancy or Nanci are—Nancy (pop. in 1831. 29,000 town, 29,783 whole commune; in 1836, 31,445 commune) [NANCY]; Rosières (pop. 2463 town, 2507 whole commune), and St. Nicholas (pop. 3006 town, 3013 whole commune) on the Meurthe; Pont-à-Mousson (pop. 6993 town, 7218 whole commune) on the Moselle; Haroué, on the Madon; Vézelize (pop. 1742) on the Uory; and Nomeny on the Seille. At Rosières (still distinguished as Rosières aux Salines, though the salt-works from which it gained its name have been long abandoned) is one of the finest of the royal studs in France; there is much meadow land round the town, and many horses are bred. St. Nicholas has a fine old Gothic church, a town-hall, and an abattoir, or public slaughter-house, lately built. There are mills, moved by water, for spinning cotton and woollen yarn, trimming manufactories, and tan-yards. Pont-à-Mousson is on a slope in the midst of a valley surrounded by fruitful hills. It is divided by the Moselle into two parts, which communicate by a bridge. There are some good houses in the town, and the streets, which are inconveniently paved with round stones, are tolerably straight. It has a good place or square surrounded by arcades; the town-hall is in this square. The principal church and the church of the Seminary are on the right bank of the Moselle; the first has two towers resembling crowns; the second has a portico overcharged with ornaments. The manufactures of the town are chiefly earthenware, especially artificial stone, much used for water-courses, reservoirs, flat roofs, &c.; and beet-root sugar, of which last there are four factories. The earthenware is exported into the adjacent departments. On an eminence near the town have been found antiquities which show that its summit was antiently occupied by a temple of Jupiter. There was formerly a university at Pont-à-Mousson, founded by Charles III., duke of Lorraine.

In the arrondissement of Château Salins are—Château Salins (pop. in 1831, 2708; in 1836, 2621), on the Petite Seille; Dieuze (pop. 3892), Marsal, Moyenvic, and Vic (pop. 3119 town, 3186 whole commune), on the Seille; Vergaville, on the Verbach, and Insming, near the Albe, a feeder of the Sarre. Château Salins derives its name, and formerly derived its importance, from its brine-springs; but the salt-works have been given up. The town is in a pleasant valley at the junction of four roads leading respectively to Metz, Nancy, Sarrebourg, and Sarreguemines. The inhabitants trade in saffron and hosiery. Dieuze has brine-springs, a salt-mine, and salt-works; there is also a manufactory of artificial soda from the refuse of the salt-works and from rock-salt. Salt has been made from the brine-springs of Dieuze for 800 years. It was a place of some importance under the Romans, who called it Decem Pagi. There are some Roman antiquities in an islet in the étang or lake of Lindre, which is near Dieuze.

Marsal is a fortress; it was bombarded by the allies in 1815, and has now a population of scarcely 1000. It is situated in a marshy plain; the foundation of the town consists of a layer of brickwork formed by the Romans. Moyenvic is a town of about 1500 inhabitants, who are chiefly engaged in making salt from the brine-springs. The town was dismantled by Louis XIV. Vic has also salt-works. The salt-mine opened in the bed of rock-salt near this town was inundated with water from a subterraneous reservoir; but another mine has been opened at Dieuze.

In the arrondissement of Lunéville are—Lunéville (pop. in 1831, 12,216 town, 12,341 whole commune; in 1836, 12,798 commune) [LUNÉVILLE], on the Vezouze, very near its junction with the Meurthe; Baccarat (pop. 1670 town, 2809 whole commune), on the Meurthe; Gerbevillers (pop. 3014) on the Mortagne; Bayon on the Moselle; Einville on the Sanon; Blamont (pop. 2281) on the Vezouze; and Badonviller (pop. 1814 town, 2297 whole commune) on the Blette, a small feeder of the Vezouze. Baccarat is at the foot of a steep hill, and near an extensive forest. One of the principal manufactories of flint and cut glass in France is in this little town. The river Meurthe brings down the timber for fuel from the Vosges, and supplies a moving power to the machinery for cutting glass, for which purpose there are two hundred lathes. The artisans with their families are lodged in the establishment, and form a population of 600. Many females in the neighbourhood find employment in different branches of this manufacture. Blamont was formerly the residence of the princes of Salm-Salm. It is now a busy little town, where calico is woven and printed,

leatner in considerable quantity made, woollen yarn spun, and common iron goods and hardwares manufactured. There are manufactories of earthenware and pottery in the neighbourhood. Badonviller has a manufactory of dies and punches.

In the arrondissement of Sarrebourg are—Sarrebourg (pop. in 1831, 2136 town, 2164 whole commune; in 1836, 2340 commune), Lorquin, and Fenéstranges on or near the Sarre; and Lixheim and Phalsbourg (pop. 1981 town, 3529 whole commune) amid the steeper slopes of the Vosges. Sarrebourg existed in the time of the Romans, by whom it was called Pons Saravi, 'the bridge of the Saravus or Sarre.' The townsmen manufacture cottons, paper, cordage, architectural ornaments, and ornaments for the fitting up of rooms. At Phalsbourg fine liqueurs are prepared. This little town, which is fortified, and defends one of the defiles the Vosges, was built in 1570 by George John, count Palatine of the Rhine, from whom it obtained its name, which in its German form, Pfalsburg, means 'the town of the Palatine.' The town is supplied with water by a fountain of admirable construction.

St. Quirin (pop. 1523 village, 1960 whole commune) and Cirey (pop. 1768 village, 2193 whole commune), though only villages, require notice for the extensive plate and other glass works established in them. Coloured glass and mirrors like those of Nürnberg are made here. St. Quirin is surrounded by vast forests which supply fuel to its glass-houses. At Cirey earthenware is manufactured.

In the arrondissement of Toul are—Toul (pop. in 1831, 7208 town, 7304 whole commune; in 1836, 7333 commune) and Dieulouard on the Moselle; Essey and Triaucourt on the Math; and Colombey near the Deuil. Toul existed in the time of the Romans, by whom it was called Tullum; it was the capital of the Leuci, a Belgic people. In some deeds of the time of the Carolingian princes, it is called Leuci. The fortifications, which were commenced under Henri IV. and carried on under Louis XIV., have been lately repaired. It was formerly the seat of a bishop. The former cathedral is an antient Gothic building with two towers resembling those of the principal church of Pont-à-Mousson. The ex-episcopal palace is a handsome building. Toul is not a place of much trade. There is a manufactory of earthenware and porcelain, which is noted for its strength and whiteness, the beauty of its enamel, and the variety of its colours. There are a high-school, an agricultural society, and several military establishments. Wine (of which the surrounding district produces abundance) and brandy are articles of trade.

The population of the above towns, where not otherwise mentioned, is of the whole commune, and from the census of 1831.

The manufactures of the department are considerable; the principal are woollen, linen, and cotton goods; trimmings and embroidery; hats, salt, glass, oil, leather, earthenware, and pottery; beet-root sugar, paper, cordage, hardwares, liqueurs, and some chemical productions. There are bell and type foundries.

The department constitutes the diocese of Nancy, the bishop of which is a suffragan of the archbishop of Besançon. It is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of that city; and in the third military division, the head-quarters of which are at Metz. It sends six members to the Chamber of Deputies.

In respect of education this department is the eighth in France. Of every hundred young men enrolled in the military census of 1828-29, sixty-eight could read and write; the average of the departments of France being only about thirty-nine.

At the time of the Roman conquest, this department formed part of the territories of the Mediomatrici in the north, and the Leuci in the south. A very small portion of the eastern side may have been included in the territory of the Tribocci, a Germanic people, who had settled on the left bank of the Rhine. Under the Romans the Mediomatrici and the Leuci were comprehended in the province of Belgica Prima, the Tribocci in that of Germania Prima or Superior. The Roman or Gallic towns within the limits of the department were Tullum (Toul), the capital of the Leuci; Scarpona, another town of the Leuci (near which Jovinus, a Roman general of horse, defeated the Allemanni, A.D. 366, and which sustained a siege against Attila), now Scarponne, or Charpagne, near Dieulouard on the Moselle;

and Decom-pagi, now Dieuze, and Pons Saravi, now Sarrebourg (not Sarrebruck, as some from the name have supposed), two towns of the Mediomatrici. The department was early comprehended in the conquests of the Franks. Its subsequent history is given elsewhere. [LORRAINE.]

MEUSE, or MAAS. [RHINE.]

MEUSE, a department in the north-eastern part of France, bounded on the north by the Belgian frontier and the department of Ardennes; on the north-east by the department of Moselle; on the south-east by that of Meurthe; on the south by that of Vosges; on the south-west by that of Haute Marne; on the west by that of Marne; and on the north-west by that of Ardennes. Its form approximates to that of an oval, having its greatest length, from north by west to south by east, from the neighbourhood of Mouzon (Ardennes) on the Meuse, to the neighbourhood of Gondrecourt on the Ornain, 85 miles, and its greatest breadth, at right angles to the length, from the neighbourhood of Revigny on the Orne, to that of Triaucourt (Meurthe) on the Math, 46 miles. Its area is estimated at 2402 square miles, which is rather below the average area of the French departments; and rather exceeds the conjoint area of the adjacent English counties Hants and Berks. The population in 1831 was 314,588; in 1836 it was 317,701; showing an increase in five years of 3113, or about 1 per cent., and giving 132 inhabitants to a square mile. Both in amount and density of population it is considerably below the average of the French departments, and still farther below the English counties with which we have compared it.

Bar-le-Duc, the capital, is on the Ornain, in 48° 46' N. lat. and 5° 9' E. long., 126 miles east of Paris in a direct line, or 152 miles by the road through Epernay, Châlons, and Vitry-sur-Marne.

The department is traversed in the direction of its length by the two ranges of hills which enclose between them the narrow valley of the Meuse. The westernmost of these ranges separates the basin of the Meuse from that of the Seine; and is known in one part by the name of 'the heights of Argonne.' A range of hills branches off from these in the south part of the department, and runs north-west by Ligny and Bar-le-Duc, separating the valley of the Aire from that of the Ornain. The heights to the east of the valley of the Meuse separate it from the basin of the Moselle.

The department belongs to the district occupied by the rocks which intervene between the chalk and the new red or saliferous sandstone. There are numerous iron-mines in the hills, also quarries of excellent freestone, and vast slate-quarries. Potters' earth and marl are dug; and the strata afford a variety of curious fossils. There were, in 1834, thirty-six iron-works in the department, chiefly in the southern part. There were in these establishments twenty-eight furnaces for smelting the ore and making pig-iron; and sixty-seven forges for the production of wrought-iron. Charcoal is the fuel chiefly employed; the extensive forests of the department afford great facilities for procuring it. In the iron-works of Abainville near Commercy coal is used.

The central valley which traverses the department in the direction of its length, and the north-eastern portion of the department, belong to the basin of the Meuse; which river enters the department about 38 miles from its source and flows north-north-west through the central valley 95 to 100 miles, past Commercy, St. Mihiel, Verdun, Dun, and Stenay, into the department of Ardennes. The navigation commences at Verdun. The Meuse receives scarcely any tributaries in this department. The Othain and the Loison (with its feeder the Tinto), which water the north-eastern parts, fall into the Chiers, a tributary which flows across the north extremity of this department and joins the Meuse in the adjacent department of Ardennes.

The eastern side of the department belongs to the basin of the Moselle, a subdivision of the great Rhenish basin; and is watered by the Ornes, the Longeau, the Yron, the Math, and other small streams belonging to the system of the Moselle.

The western side of the department belongs to the basin of the Seine. The Aire, a tributary of the Aisne, rises in the south part and flows nearly parallel to the Meuse, about 50 miles past Clermont-en-Argonne and Varennes, into the department of Ardennes. The Aisne itself has its source and a small part of its course in the department. The Ornain, or, as it is called in the lower part of its course, the Orne, enters the department on the south and flows north-

west, 50 miles past Gondrecourt, Ligny, and Bar-le-Duc, into the department of Marne. The Saulx, a feeder of the Orne, also waters this part.

There are several étangs, or pools, in the department, especially in that part which belongs to the basin of the Moselle. The most considerable, which is about two or three miles long, and in one part nearly two miles broad, is near the village of Woel. The river Yron flows through it.

The navigation of the Meuse within this department is given in the official statements at 53 miles; there are no navigable canals.

The Routes Royales, or government roads, had in 1837 an aggregate length of 317 miles, of which the whole, excepting 5 or 6 miles, were in good repair. The principal roads are those from Paris by Châlons-sur-Marne (Marne) to Metz (Moselle); and from thence to Mayence and Frankfort in Germany; and from Paris, also by Châlons to Nancy (Meurthe) and Strasbourg (Bas Rhin). These roads both cross the department from west to east, the former in the northern part, through Clermont-en-Argonne and Verdun; the latter in the southern part, through Bar-le-Duc and Ligny. The road from Paris by Longwy (Moselle) to Luxembourg in Belgium, and Treves and Coblenz in Germany, branches off from the Metz road at Verdun, and runs north-eastward through Etain. A road from Dijon (Côte d'Or), Langres (Haute Marne), and Neufchâteau (Vosges), runs along the valley of the Meuse by Commercy, St. Mihiel, and Verdun, into the department of Ardennes, and so into Belgium; with a branch from between Neufchâteau and Commercy, to Ligny and Bar-le-Duc. A road from Troyes (Aube) to Nancy (Meurthe) crosses the southern part of the department.

The Routes Départementales had at the same time an aggregate length of 170 miles; of which the whole (except about 20 miles) was in good repair. The bye-roads and paths had an extension of above 6000 miles.

The climate of the department is cold (especially on the higher lands, some of which are of considerable elevation) and moist, but it is considered healthy. The soil in the valleys and on the hill sides is very fertile: a large portion of it consists of a rich loam. About 840,000 acres, rather more than half the surface of the department, is under the plough. The produce in grain is very considerable, especially in wheat, barley, and oats: that of barley is nearly three times as much as the average produce of the French departments; that of oats is above the average, but, from the great number of horses reared, is insufficient for the consumption of the department. But little rye and maslin, or mixed corn, is grown: and neither maize nor buckwheat is at all cultivated. Potatoes are grown in considerable quantity, also rape-seed for oil, flax, hemp, pulse, and fruit of every kind, but especially gooseberries. Orchards and gardens occupy above 18,000 acres. The vineyards occupy about 35,000 acres, and are chiefly in the south-west part of the department. The wines are in general of good quality, especially the red wines of Bar-le-Duc. The woodlands occupy from 340,000 to 350,000 acres, of which about 100,000 acres belong to the state, about 220,000 to the communes and to the public establishments; the rest is private property. The chief forest trees are the oak, beech, and elm. The timber and firewood supply the wants of the department, and furnish an article of export to the department of Ardennes and the departments in the basin of the Seine.

There are about 124,000 acres of meadow land, the best of which is in the valley of the Meuse; and 30,000 acres of heath or other open pasture. A great number of horses of a small breed are reared; the whole number in the department may be estimated at more than 60,000, above twice the average number in the other departments. They are employed, to the exclusion of oxen, in nearly all the labours of agriculture. The number of horned cattle is about equal to the average of the departments, viz. about 80,000. The dairy is much attended to; excellent butter is made, and cheese, which resembles that of Gruyère. The number of sheep is not great; the breeds have been improved by crossing them with those of England and Holland. There are some pigs reared, and a few goats; poultry is abundant. The forests contain wild boars and roebucks; and small game abounds in all parts of the country. A great number of red-breasts are taken every winter. The rivers and pools furnish plenty of fish, especially the pike, perch, loach, salmon-trout, and cray-fish.

The department is divided into four arrondissements as follows:—

		Area in sq. Miles.	Population in 1831.	Population in 1836.	No. of Communes.
Bar-le-Duc,	S.W.	569	82,134	80,952	128
Commercy,	S.E.	755	84,610	86,013	181
Montmédy,	N.	498	66,947	68,495	131
Verdun,	Central.	580	80,897	82,241	149
		2402	314,588	317,701	589

It is subdivided into 28 cantons, or districts, each under a justice of the peace.

In the arrondissement of Bar-le-Duc are—Bar-le-Duc (pop. in 1831, 12,496) [BAR], Ligny (pop. 3212), and Revigny (pop. 1598), on the Orne; Vaubecourt, on the Aisne; Beaufort, on the Aire; and Ancerville (pop. 2239) near the south-western boundary of the department. Ligny, distinguished as Ligny-en-Barrois, is a pleasant little town, antiently fortified, but the walls are now in ruins. The parish church contains the monument of the Maréchal de Luxembourg. The inhabitants spin cotton-yarn and weave cotton goods, and carry on trade in wool and timber.

In the arrondissement of Commercy are—Commercy (pop. in 1831, 3622; in 1836, 3716), Maxey, Vaucouleurs (pop. 2157), Void, Sorey, or Sorey (pop. 1634), and St. Mihiel (pop. 5822) in the valley of the Meuse; and Gondrecourt on the Orne. Commercy is a pleasant town on the left bank of the Meuse, surrounded by a thickly wooded district. The streets are remarkably straight. There is a fine range of cavalry barracks, formerly a château built by the Cardinal de Retz. The inhabitants manufacture cotton-yarn and goods; there are also some iron-works. Vaucouleurs is built on the slope of a hill on the bank of the Meuse, and is surrounded by meadows. The inhabitants manufacture stockings, linens, and cotton goods. There are some tan-yards. Void is the dépôt for rape-oil, which is made in abundance in the neighbouring part of the valley of the Meuse. It has some tan-yards, also paper-mills, and oil-presses moved by water. St. Mihiel was formerly a fortified town, and was besieged by Louis XIII. in person, who incurred so much danger in the siege, that on capturing the place he caused the fortifications to be razed. The situation of the town is very picturesque, but the houses are old. There was antiently a Benedictine abbey, the foundation of which gave rise to the town. The parish church, formerly conventual, contains the remains of several princes of the house of Lorraine and counts of Bar. Another church, that of St. Etienne (St. Stephen), is adorned with a fine piece of sculpture, a 'holy sepulchre' carved out of a single block of fine white stone, by Ligier Richier, a native of this part of France, and a pupil of Michael Angelo. There are at St. Mihiel cotton and woollen cloth manufactures, oil-presses, and tan-yards. The inhabitants trade in corn and wine; there are three yearly fairs. There are a subordinate court of justice, and one or two fiscal or administrative government offices; a high school, and a public library. There is a camp, supposed to have been occupied by Julius Caesar, near the town.

In the arrondissement of Montmédy are—Montmédy (pop. in 1831, 2195; in 1836, 2201) on the Chiers; Marville on the Othain; Jametz on the Loison; Damvilliers on the Tinto; and Dun and Stenay (pop. 2681 town, 3140 whole commune) on the Meuse. Montmédy is an ill built town, but is of some consequence as a fortress. In 1815, being defended by about 100 soldiers of the line, and some national guards and custom-house officers, making in all 600 men, it resisted the attempt of a corps of 1500 Prussians to surprise it; the assailants lost 500 men. The inhabitants manufacture hosiery and hats, and leather: there are saw-mills and oil-mills. Stenay is a pleasant situation, and was formerly a place of strength, but was dismantled, A.D. 1654, by Louis XIV. There are barracks. There is in the town an extensive cooperage, in which the moving force of water is employed. There are considerable iron-works near Stenay. In the village of Avioth near Montmédy is an antient church accounted one of the finest specimens of Gothic architecture in France.

In the arrondissement of Verdun are—Verdun (pop. in 1831, 9978; in 1836, 10,577) [VERDUN], in the valley of the Meuse; Clermont-en-Argonne [CLERMONT] and Varennes (pop. 1652), on the Aire; Etain (pop. 3034), on the Orne; and Fresnes, on the Longeau. Varennes was the place where Louis XVI. and his family were stopped in their at-

tempt to escape from France. There is a glass-house in the town. Etain or Estain is a tolerably neat town in a marshy plain. The inhabitants manufacture woollen cloth, flannel, leather, and paper. This town gave title to the French admiral Count d'Estaing.

The chief manufactures of the department are iron goods, glass bottles, paper, earthenware, and leather; cotton hose, lace, and cotton and woollen fabrics; and wicker-work. There are brandy distilleries and oil presses. The chief trade is in agricultural produce, corn, wine, oil, timber, &c., and in iron.

The department forms the bishopric of Verdun, the bishop of which is a suffragan of the archbishop of Besançon. It is in the jurisdiction of the Cour Royale and the circuit of the Académie Universitaire of Nancy; and in the second military division, of which the head-quarters are at Châlons. It sends four members to the Chamber of Deputies.

In respect of education this department is in advance of every other in France. Of every hundred young men enrolled in the military census of 1828-29, seventy-four could read and write; while the average of the departments was under forty.

The department antiently formed part of the territories of the Verodunenses and of the Leuci: small portions of it were comprehended in the territories of the Remi, the Medromatrici, and the Treviri or Treveri: all these were Belgic nations. In the Roman division of Gaul the Remi were included in the province of Belgica Secunda; the other nations in Belgica Prima. Verodunum (or, as it is written in the Itinerary of Antoninus, Virodunum), capital of the Verodunenses, was the modern Verdun; Nasium, a town of the Leuci, was the modern Naix or Nais, a village on the Orne above Ligny; and Caturigis was in the vicinity of Bar-le-Duc. On the overthrow of the Western empire, the department came into the hands of the Franks, and formed part successively of the kingdoms of Austrasia and Lotharingia or Lorraine. The greater part of it was comprehended in the duchy of Lorraine and Bar; and the remainder in the bishopric of Verdun, one of Trois Evêchés (three bishoprics); or in the county of Champagne and the county of Clermont.

MEW, a name for the *Gull*. [LARIDÆ] In falconry it signifies the place where hawks are kept.

MEXICAN STATES, THE UNITED, a federal republic in America, occupy the north-western and by far the greatest part of the Mexican isthmus, together with the south-western portion of the main body of North America: they lie between 15° and 42° N. lat. and 87° and 125° W. long. On the east the United Republic is washed by the Gulf of Mexico and the Bay of Honduras, a division of the Caribbean Sea; and on the south-west and west by the Pacific, which here forms the long Gulf of California. On the south-east it borders on Guatemala, one of the states of Central America, and on the British colony of Belize. On the north-east and north it is bounded by the states and territories of the United States of North America. The boundary-line on this side, according to a treaty, begins on the east at the mouth of the river Sabine, and follows its course northward to the point where it is intersected by 32° N. lat.; it then continues along the meridian of 94°, until it reaches Red River. The line ascends the last-mentioned river to the point where it passes the meridian of 100°, and proceeds along this meridian northward to the Arkansas river, which constitutes the boundary-line westward to its very source in the Rocky Mountains. From this range westward to the shores of the Pacific, the parallel of 42° separates the territories of both republics. As large tracts along the northern boundary are quite unknown, the area of this extensive country can only be approximated to. It probably occupies a surface of about 1,500,000 square miles, or more than seven times the area of France.

Surface; Soil; Climate; Rivers.—This immense country is divided by nature into three regions, each of which is marked by different features. The first comprehends the countries lying to the east of the isthmus of Tehuantepec, which is crossed by the meridian of 95° west of Greenwich: we shall call it the **Eastern Region**. The second extends from the meridian of 95° in a curved line to the mouth of the Rio del Norte on the east (26° N. lat.), and to the most northern recess of the Gulf of California (32° N. lat.) on the west: it is the **Central Region**, or **Anahuac**. The third or **Northern Region** comprehends the countries situated

north of a line drawn from the mouth of the Rio del Norte to that of the Colorado.

The **Eastern Region** comprehends the peninsula of Yucatan, the western declivity of the table-land of Guatemala, the plain of Tabasco, and the isthmus of Tehuantepec. The north-eastern extremity of the peninsula of Yucatan, near Cape Catoche, is hardly more than 150 miles distant from Cape S. Antonio, the most western extremity of the island of Cuba. Through the strait formed by these headlands a current with considerable velocity sets in to the north. The earthy particles brought by this current are deposited along the northern and western shores of the peninsula, where the current is much less rapid. These shores have no harbours, but only roadsteads, which during the northern gales are very unsafe; but along the eastern shores there are several harbours. The shores are sandy and flat. The level country extends to a considerable distance inland, whilst the centre of the peninsula is occupied by a range of low hills, or rather a long and comparatively narrow table-land enclosed by two ranges of low hills. The country along the Bay of Honduras is well watered, and exhibits a vigorous vegetation, both in its trees, which are of heavy growth, and in the great variety of its plants; but the soil is nearly uncultivated, the scanty population being chiefly employed in cutting mahogany, with fustic and several other dye-woods. The hilly district in the interior, as well as the flat country on the northern coast, has a sandy soil, and no spring-water is found from Cape Catoche to the mouth of Rio de S. Francisco, which empties itself into Campeachy Bay; and even as far south as the Laguna de Terminos spring-water is scarce. Its vegetation is scanty: the trees are stunted, and the plants of a languid growth, except during the rainy season (from May to September); but as the climate, though exceedingly hot, is healthy, it is much better inhabited and cultivated than the eastern shores. The rains, though commonly abundant, sometimes fail, and such an event is followed by dearth.

The hills in the interior grow higher towards the point where the peninsula is connected with the table-land of Guatemala. The larger and higher portion of this table-land belongs to the state of Guatemala, and it is traversed by a ridge of high hills between the towns of Totonicapán and Gueguetenángo. [CENTRAL AMERICA.] From this ridge, which stands on a base elevated probably about 5000 feet above the sea, the country descends rather rapidly to the west, and where the boundary-line of Mexico and Central America crosses the table-land it is probably less than 3000 feet high. It continues to descend until it meets the plain of Tabasco, north of 17° N. lat. Its surface is far from being level, as it is furrowed by numerous watercourses: so that it may rather be considered as a succession of ridges of hills and of valleys than as an inclined plane. The climate is in general healthy, and its productions vary according to the different elevations of the surface. In some the productions of the West Indies are cultivated; in others wheat and some European plants are grown.

The plain of Tabasco begins on the east, at some distance east of the lagune of Terminos, and extends westward to Partida Rock, a moderately elevated cape, in which a range of hills, including the volcano of Tuxla, terminates (16° W. long.) on the shores of the Gulf of Mexico. This plain is more than 250 miles long, and extends inland from 50 to 120 miles. Its surface is a dead level, and the soil alluvial. Being very fertile, it is covered with a thick forest of heavy growth, but is little cultivated on account of its being subject to inundations, and generally under water for several months during the rainy season. It seems that this part of the Mexican States suffers as much from the superabundance of water as other parts from the want of it. To this circumstance, and to the great heat of the summer, the unhealthiness of this tract is to be attributed. Besides the common objects of agriculture in countries similarly circumstanced, as maize, plantains, and manioc, it produces a large quantity of cocoa and some coffee. Vanilla and indigo are stated to be common in the woods. Though the coast is generally low, parts of it are higher than any other portion of the coast of the American continent along the Gulf of Mexico. Between the lagune of Terminos and the mouth of Tabasco river are the heights of S. Gabriel, a range of hills running east and west about 30 miles, at a short distance from the shore; and where the plain terminates on the west is Cape Partida Rock, the extremity of a somewhat elevated and rocky shore, which extends

about 30 miles south-south-east and north-north-west. The Laguna de Terminos is about 60 miles long from north-north-east to south-south-west, and 30 miles wide on an average; but in many places it has hardly four feet of water, and the three or four channels by which it is connected with the gulf are hardly passable for large boats. The water is brackish. The plain of Tabasco is watered by a considerable river, the Rio de Tabasco, and its two branches the Usumasinta and the Grijalva, of which the former rises in two branches on the eastern corner of the table-land of Guatemala, and flowing in a direction generally north by west, forms a considerable cataract south of 17° N. lat., where it descends from the table-land. Above this waterfall it is navigable for canoes, and below it for larger boats. This is also the case with its tributary, Chacamas: this river rises in the hills on which stand the ruins of Palenque, the most northern offsets of the table-land of Guatemala. The Usumasinta joins the Rio de Tabasco a few miles above its mouth, after a course of more than 300 miles. The other branch, the Grijalva river, rises in the range of high hills in Guatemala, between the towns of Totonicapán and Gueguetenángo, and runs with many bends in a wide valley in a north-west direction, until it issues from it near the isthmus of Tehuantepec, where it turns to the north-east by a bold sweep, and receives the name of Rio de Tabasco. It traverses the whole plain in a rather oblique direction, and appears to be navigable in this part for boats of considerable burden. Before it joins the Usumasinta it is navigable for vessels of moderate size, which ascend as far as Villa Hermosa. After having joined the Usumasinta, it falls into the Gulf of Mexico at Port Victoria, after a course of about 350 miles.

The plain of Tabasco occupies the northern portion and about one half of the isthmus of Tehuantepec. The southern half comprehends a mountain-ridge and a smaller plain. The most western declivity of the table-land of Guatemala assumes the form of a ridge at about 94° W. long., which, running due east and west, connects the last-mentioned table-land with the elevated plains of Anahuac. This ridge (or rather these ridges, for there are several, running nearly parallel to one another) occupies between 35 and 40 miles of the isthmus. It is called Cerro Pelado, and probably does not rise above 2000 feet. Being entirely covered with trees of heavy growth, it is also known by the name of the Forest of Tarifa. The southern plain, or that of Tehuantepec, is about 25 miles wide, and extends along the Pacific from the boundary of Guatemala to some distance west of the town of Tehuantepec. It has a very hot but rather dry climate, and the soil, though not distinguished by fertility, is capable of producing several tropical plants. It is supposed that an easy line of communication may be established across the isthmus of Tehuantepec, between the Gulf of Mexico and the Pacific, as the two seas are only 140 miles distant, and the two plains are watered by navigable rivers. The river Chimalapa, descending from the Cerro Pelado, traverses the plain of Tehuantepec; and though its whole course perhaps does not exceed 50 or 60 miles, it has much water, and is navigable to S. Miguel de Chimalapa, a distance of about 30 miles. On the same Cerro, but within the northern ridges, rises the Rio Huasacualco, which first turns to the west, and then to the north, breaking through some of the ridges of the Cerro Pelado. In this part of its course it is joined by numerous small rivers, which descend from the western declivity of the table-land of Mixtecapán, and it soon becomes a powerful river, though it is not navigable on account of rapids or cataracts. As soon as it enters the plain of Tabasco its course is gentle, and there is no further obstruction to the navigation. Its mouth, which is situated in the south-western recess of the Gulf of Mexico, is however so choked by a bar and shoals, that vessels even of small size cannot enter it.

The *Central Region* of the Mexican States may be called Anahuac, though this name was used before the Spanish conquest to designate only the country as far north as 21° N. lat., and did not comprehend the northern district, which we include in this region. In its natural features it exhibits great variety.

We begin our survey with the eastern coast, which is low and sandy from the Punta de Rocca Partida ($18^{\circ} 40'$ N. lat.) to the most north-eastern corner of the Gulf of Mexico (about 29° N. lat.), and still farther eastward. It runs on in a continuous line, without being broken by inlets or bays; and

consequently it contains no harbours except those formed by the mouths of the rivers; and even these are only unsafe roadsteads, as the rivers of this coast (between $18^{\circ} 40'$ and 22° N. lat.), with the exception of the Rio Alvarado, have only water enough in the rainy season. North of 22° several rivers of considerable size fall into the sea, but except at their mouths the coast cannot be approached by vessels, as it is lined by long, low, and narrow islands, which lie parallel to, and from two to six miles from it. The channels by which these islands are separated are too shallow to admit even boats. The country adjacent to the shores, and from three to ten miles inland, is very low, but is defended from the sea by sand-hills rising from 50 to 200 feet high. The soil is sandy and destitute of vegetation, with the exception of a few stunted shrubs and some hardy plants. At the back of this low sandy tract the country rises gradually to the foot of an extremely steep ascent, which constitutes the eastern edge of the extensive table-land farther west. The country which lies between the shores and the steep ascent varies in width. At Vera Cruz (near 19° N. lat.) it is only about 60 miles wide, and this may be considered as its average breadth south of 22° . Farther north it widens, and at Saltillo (26° N. lat.) it is more than 180 miles across. Its acclivity can only be called gradual in comparison with the steep ascent which borders it, for, as far as is known, it attains an elevation of 2500 or 3000 feet at a distance of only 50 miles from the sea. In the wider portion of this tract, north of 22° N. lat., a small number of isolated hills, generally of considerable height, are scattered over the inclined plain; those north of Monterey are the highest, and are visible at a great distance.

This tract is comprehended in the Tierras Calientes, or 'hot countries.' The seasons are divided into the winter, or the season of the north winds, and the summer, or season of the breezes. The former lasts from October to April, during which time the north winds (los nortes) are prevalent, and frequently blow with the force of a hurricane, sometimes for days together. They are the terror of navigators on these shores. During this period the coast is healthy, and the vomito prieto, or yellow fever, ceases. The mean heat of this season is 71° of Fahrenheit, but whilst the north winds are blowing the thermometer sometimes descends to 60° . Rain is not rare during this season, but the showers are only of short duration. During the summer the heat is great; the mean temperature is about 81° , and in July and August is about 82° . The rains are not heavy before June, but in that month they descend in torrents nearly every day for several hours. In July alone about fifteen inches of rain fall, or two-thirds of the mean annual quantity at London. In this season, but especially towards the end of it, in September and October, the vomito prieto is prevalent, and very destructive among the white inhabitants. This disease however only occurs in the lower part of the country: places which are at an elevation of 2500 feet are entirely free from it. The mean annual heat of this tract is 77° . It is extremely well adapted for the cultivation of all tropical products, and as its soil, with the exception of the sandy shores, is possessed of a considerable degree of fertility, it produces rich crops of Indian corn and rice where it can be irrigated. Bananas, pine-apples, oranges, and manioc are also cultivated. The products adapted for exportation are chiefly coffee, sugar, and cocoa, and a small quantity of cotton; vanilla and jalap are collected in the woods, with which a great part of this region, especially that near the steep ascent, is thickly covered.

The steep ascent which bounds this tract on the west rises in some places in terraces, which lie between the declivities; and in such places the ascent occupies a considerable space; but in other parts it rises from 5000 to 6000 feet in a distance generally not exceeding ten miles in width, and frequently much less. The acclivity is so steep that on the whole line there are only two places where it is practicable for carriages, namely, at Xalapa, near Vera Cruz (19° N. lat.), and at Santillo, west of Monterey (26° N. lat.), though its whole length probably does not fall short of 600 miles. The rocks are generally too steep to maintain any vegetation beyond a few plants, but in the narrow ravines which intersect the acclivity a vigorous vegetation is found; in the lower part there are many oak-trees, and in the higher large pines.

The steep ascent just described constitutes the outer edge of the elevated plains of Anahuac, which extend westward to a great distance. The edge itself is lined by a continuous

series of hills rising in general only to a moderate elevation above the table-lands, but some of them attain a great height, as the Coffre de Perote, near the road leading from Vera Cruz to Mexico, which is 13,415 feet above the sea-level, and 5723 feet above its base, and the peak of Orizáva, which attains a height of 17,373 feet. The heights which line the margin of the table-land do not form a continuous chain, but appear rather isolated in the southern districts. North of 22° N. lat. however they constitute a continuous range of high mountains, considerably elevated above the adjacent table-land; and this chain extends to the north of the Real de Catorce (24° lat.). North of the group which surrounds this place they again sink down nearly to the level of the table-lands.

The elevated plains of Anahuac are divided into two parts by a range of mountains, which traverses them in a general eastern and western direction, and is called Sierra Madre. This chain begins not far from the eastern edge, near 21° N. lat., west of Tlacolula, with the mountains of La Encarnación, whence it continues in a west by north direction to San Felipe (21° 40' N. lat.), which town is situated in a comparatively small plain enclosed by two branches of the range. Here an elevated and wide offset branches off to the southward, and stretches over the plain for about 50 miles, terminating with the group in which the mines of Guanajuato are situated.

West of S. Felipe the range declines to the north-north-west, and its continuity seems to be broken into isolated ridges, as the Sierra de Altamira, about twenty miles east of Aguas Calientes, and the group of mountains which contain the mines of Zacatecas. But at no great distance west of Zacatecas the Sierra Madre re-appears in the decided shape of a mountain-range, and occupies a width of a hundred miles from east to west. Its direction is from south-east to north-west as far north as 28° N. lat., where it declines to the north, and terminates near 32° N. lat., in an isolated mountain-group called the Sierra de las Espuelas, having gradually diminished both in elevation and width. The elevation of this range is almost entirely unknown. The mountains of La Encarnación rise more than 10,000 feet above the sea, and about 4000 above their base; those enclosing the plain of S. Felipe are probably as high, especially those of La Tlachiquera. It would also seem that the range stretching north-west from Zacatecas is not less elevated for a considerable extent, though it sinks lower north of 28° N. latitude.

The elevated plains which spread out west of the steep ascent occupy the greatest part of the surface of Mexico. They are widest between 19° and 20° N. lat., where they occupy 360 miles from east to west. This extensive tract of country however is not one plain, but divided into four plains, unequal in extent, and separated from each other by ranges of hills, which rise from 500 to 2000 feet above their base. The most eastern plain may be called the plain of Tlascala, from the town of that name, which is situated nearly in its centre. Its surface is from 7000 to 7500 feet above the sea, and it occupies the space between 97° and 98½° W. long., and between 18½° and 20° N. lat. Its surface is pretty level: the hills, which occur on it at considerable distances from one another, rise only to a very moderate height, and the depressions are few and of small extent. Two isolated peaks of considerable elevation, the Cerro de Pizarro and Mount Malinche, are near the road which leads from the sea to Mexico. The parts of this plain which are contiguous to the eastern edge of the table-land are very sterile, the ground being covered with lava, and producing only a coarse grass, on which sheep pasture. This sterile tract, called *el mal país*, occupies about one-third of the plain. Farther west the soil improves, and in many places the ground is covered with maize, wheat, and barley, or laid out in plantations of American aloes. The chain of hills which divides the plain of Tlascala from that of Tenochtitlan, contain the peak of Istaccihuatl (15,704 feet above the sea), and the volcano of Popocatepetl (17,884 feet), which last is the highest mountain in Mexico. The plain of Tenochtitlan, lying west of that of Tlascala, is between 19° and 20° N. lat. and 98° 30' and 99° 30' W. long., and about 7480 feet above the sea. Farther west is the plain of Toluca, which extends to 100° W. long., and is somewhat smaller in extent than that of Tenochtitlan, but likewise surrounded by chains of hills. In the southern chain is the Nevado de Toluca, which is 15,160 feet above the sea, and through the northern chain the Rio de Lerma forces its

course. The surface of this plain is in many places uneven and broken, but it contains also extensive levels. As it is nearly 9000 feet above the sea-level, it is too cold to produce wheat, and it serves chiefly as pasture-ground. The most western of these extensive plains is that of Michoacan, which between 19° and 20° N. lat. extends from 100° to 104° W. long., and approaches the Pacific within about 30 miles. Its surface in the eastern districts is about 6500 feet high, but towards the west it sinks down to 5500 feet. Far from being so level as that of Tlascala, this plain exhibits several broken and high ridges of hills, which enclose valleys of moderate width and great fertility. The mountains are covered with a fine growth of timber. The level country is fertile, and produces abundantly every kind of grain, but its elevation above the sea is still too great to admit the cultivation of tropical products. Nearly in the centre of this plain is the lake of Patzcuaro, famous in the history of the ancient kingdom of Michoacan, whose capital, Tzintzontzan, was built on its banks. Towards the western extremity of the plain is the peak of Tancitaro, which is probably more than 10,000 feet above the sea.

From the western edge of the table-land of Michoacan, on which the small town of Zapotlan is built, the country declines rapidly to the plain of Colima, which seems to resemble in most respects the low tract along the Gulf of Mexico. It appears to be generally level and not much elevated above the sea. On this plain the isolated volcano of Colima rises to a great height. This country is fertile, and is capable of producing all the tropical plants; but it is badly cultivated.

On the north the table-lands just mentioned border on others of a similar description. On the south the country descends rapidly and with a very irregular surface, except where it borders on the plain of Tlascala. This plain is joined on the south by that of Mixtecapan, which stretches from about 18° 30' N. lat. southward to the very shores of the Pacific, where it terminates with high mountains, leaving only a narrow tract between them and the sea, from the plain of Tehuantepec on the east to the mouth of the Rio Yopez on the west, a space of 300 miles. We are less acquainted with the features of the table-land of Mixtecapan than with other parts of Mexico, as it has rarely been visited by European travellers, though it contains the best cultivated and most populous districts of the republic. It is however certain that the whole region, with the exception of a few depressions and the low tract on the coast, forms a table-land about 5000 feet above the sea. Its surface appears to be undulating, and sometimes to rise into hills. Towards the plain of Tabasco a chain rises to a greater elevation, though the highest summit, the peak of Senpueltepec, probably does not exceed 7500 feet. Indian corn and other grains are grown in abundance, and a great quantity of cochineal is collected on this table-land.

The table-land of Mixtecapan, stretching south and north, and extending westward to 98° 30', forms nearly a right angle with the table-land which stretches east and west over the Mexican isthmus, between 19° and 20° N. lat. The countries which fill up this angle do not present in the least degree the features of a table-land, being covered with numerous narrow ridges running generally east and west, with valleys between these ridges sometimes wide enough to be called plains. Both the ranges and the valleys grow lower as they approach the shores of the Pacific. In passing the low ridges which enclose the table-lands of Tenochtitlan, Toluca, and Michoacan, on the south, we descend immediately to a country hardly 3000 feet above the sea, as is indicated by the sugar plantations which occur at Istla (3100 feet) and at Cuantla y Amilpas, not more than 30 or 40 miles south of the table-land of Tenochtitlan. Farther south the descent is less rapid, as the valleys, which are only 30 or 40 miles from the Pacific, are still about 2000 feet above it. The descent again becomes more rapid near the shores, on the margin of which there is a narrow level tract intersected with salt lagunes. This region is traversed nearly in its whole width from east to west by a river of considerable magnitude, the Rio Bolsas, or Rio de Zacatula, whose course exceeds 200 miles, its source being near the western edge of the plain of Mixtecapan. But this river is not navigable, its course being very rapid, even at its mouth. Towards the northern margin of this region is the volcano of Jorullo, which stands in the middle of a plain 2890 feet above the sea, the volcano itself being 4114 feet above the sea, or 1224 feet above its base. This volcano was formed

on the 29th September, 1759, in a violent eruption, by which a surface of between 24 and 30 square miles was raised several feet above the level of the plain. The volcano is surrounded by numerous conical hills of moderate elevation, from which smoke is continually issuing. From the mouth of the Rio Bolsas westward a low level plain extends along the Pacific, which joins that of Colima, and spreads about 30 or 40 miles inland. It is a *tierra caliente*, resembling, in climate, fertility, and productions, the low coast along the Gulf of Mexico, and, like the latter, it is very unhealthy; but the yellow fever, or vomito prieto, does not visit the shores of the Pacific. The mean annual temperature of these shores is considerably higher than that of the shores of the Gulf of Mexico, the thermometer, even during the cold season, hardly descending below 82° , and nearly all the year round maintaining itself in the day-time between 86° and 95° . This difference must be attributed to the absence of cold winds on this coast. The gales by which it is visited rather resemble hurricanes, and blow during the months of July and August from the south-west: sometimes they occur as late as September and October. From October to May the air is in general calm, and the sky cloudless; but the sun is nearly invisible on account of a fog, of an olive colour, which covers the whole sky in its upper regions, and does not affect the hygrometer. In this season some gales blow from the north-east or north-north-east, which are called the gales of Tehuantepec.

North of 20° N. lat. is the table-land of Queretaro, which extends to the ridge of the Sierra Madre, on the east to about 21° N. lat., but on the west to $21^{\circ} 30'$. That portion of it which lies east of 100° W. long. is in general about 6500 feet above the sea-level. Its surface is broken by single groups or short ranges of hills, which rise from 1000 to 1500 feet above the plain; but still there occur many level tracts of considerable extent and great fertility. This region contains numerous productive mines. The western and greater portion of the table-land (between 100° and 102° W. long.) is nearly a plain, rarely interrupted by hills. Its surface is on an average only 200 or 300 feet lower than that of the eastern portion. The central part of it is occupied by one of the richest agricultural districts on the Mexican isthmus, known under the name of Baxio, which extends from the neighbourhood of Queretaro along the Rio Santiago westward for several miles west of Salamanca, and thence in a northern direction to Leon. Its length exceeds 100 miles, and its average width probably 30 miles. It is covered with corn-fields, which, being irrigated by canals, yield rich crops of Indian corn and wheat. In the other districts many sterile tracts occur, which are either covered with stones, and then called *pedregal*, or with lava, in which latter case they always receive in Mexico the name of *malpais*. The remainder is rather fertile, but cannot be cultivated where there are no means for irrigation, as the rains are far from being abundant in this region. Where a depression occurs in which the rain-water accumulates, a stone wall is generally erected to prevent it from running off, and the artificial pond or tank so made is called *presa*. By far the greater part of the country however cannot be irrigated at all, and is used only as pasture-ground. Some of the cattle estates are of immense extent, and keep many hundred thousand head of cattle and sheep. On this table-land the *barrancas* are more frequent: they indeed occur in other parts of the isthmus of Mexico, but not in such number nor of such dimensions. A *barranca* is a depression in the level country, having always a steep declivity, and descending frequently 1000 feet below the general surface of the country. These depressions are sometimes three or four miles wide, and still longer: they are covered with trees of a vigorous growth, which form a striking contrast with the bare surface of the table-land. The climate of these *barrancas* is considerably milder than that of the country about them, and approaches in some cases to that of the *tierras calientes*. Vegetation follows the course of a small stream which runs in the centre of the *barranca*. Several small towns are built in these depressions of the table-land.

It is hardly possible to determine the western boundary of the plain of Queretaro, as it is not marked by a continuous ridge of hills. From about $101^{\circ} 30'$ W. long., and from that point where the Sierra Madre turns northward, the country descends very gradually to the west, but with a broken surface, so as to present a succession of hills and valleys with some intervening plains, usually of no great extent; the plains in some places occupy the summit of the higher

country, and are called *mesa* (table-land). The descent terminates about the meridian of Zapotlan, or Zapotlanéjo ($102^{\circ} 30'$), where the productions of the *tierras calientes* appear, and the general level of the country extending to the shores of the Pacific may be estimated at about 4000 feet above the sea. This region, called the Plain of Xalisco, cannot be called a table-land, as its surface is very uneven, being in many places intersected with hills, frequently rising to a great height, with a steep ascent, though flat tracts of great extent are numerous, among which that about the town of Guadalajara is distinguished by fertility. Though this region, as being among the *tierras calientes*, might produce most tropical plants, Indian corn and wheat constitute the principal articles of agriculture. The extent to which wheat is grown shows that the greatest part of this region cannot be below 4000 feet above the sea. In this country is the lake of Chapála, which is about 90 miles in length, and from 12 to 18 miles in breadth: the surrounding hills rise to a considerable elevation, and descend rapidly to the water's edge. The lake contains the island of Mescála, on which a number of Indians resisted the arms of the Spaniards from 1811 to 1814. The lake is noted for a kind of fish called *pescado blanco*, which occurs in most of the lakes of the table-lands, but nowhere attains such a size as in the lakes of Páscuaro and Chapála, whence it is sent to Mexico, slightly sprinkled with salt or preserved in snow.

The Rio Santiago, or Rio Grande, the largest of the rivers of the Mexican isthmus, principally traverses the regions just mentioned, having its mouth at S. Blas ($21^{\circ} 32'$ N. lat. and $105^{\circ} 18'$ W. long.). This river rises in the highest of the table-lands, in that of Toluca, in a lake situated at the base of the range which divides this table-land from that of Tenochtitlan, and in an extensive morass surrounding the small town of Lerma, whence it is called, in the upper part of its course, Rio de Lerma. Its course across that region is rather gentle, until it breaks through the range of hills which separates the table-land of Toluca from that of Queretaro. It flows through the Baxio with a gentle course, and its waters are abundantly used for irrigation. Where it leaves the plain of Queretaro, it is closely hemmed in by precipitous mountains, full of rapids and bars, and runs quickly over a stony bed; in this part of its course navigation is entirely impossible, except for small canoes in the spaces between the rapids. On approaching the lake of Chapála its course becomes gentle, and before it enters the lake it passes through an extensive level tract, which is inundated by the river during the rains and is swampy all the year round. It enters the lake a few miles below La Barca, where it is 90 yards wide. The waters of the river may easily be distinguished from those of the lake, from which it issues on the north side not far from the town of Ocotlan, where it is 200 yards wide, and flows with an even and uninterrupted course to the Puente del Rio Grande, near Guadalajara, where there occur in the space of less than three miles between fifty and sixty falls. Its course farther down, though less obstructed, is still very rapid, and at present at least not used for navigation. The course of this river considerably exceeds 400 miles in length.

The eastern part of the table-lands is drained by the river Panuco, which rises in the lake of Zumpango on the table-land of Tenochtitlan. The waters of this lake are carried by the canal called the Desague de Huehuetoca to the Rio de Tula or Moctezuma [Mexico], which runs in a northern direction, inclining a little to the east to Tamiasinchali, where it is called the Rio de S. Juan. From this place it passes in the same direction to Miraflores, S. Juan, and Tanquichi. In this latter part of its course the river, which near its source is extremely rapid and frequently rushes forward like a torrent, becomes more gentle, and canoes may ascend it to S. Juan; but above Tanquichi the rapids are numerous and violent. From the last-mentioned place to Panuco, a distance of 87 miles by the numerous windings of the river, it may be navigated by large boats. Between these places the Rio de San Juan is joined, from the west, by the river Tamoin, and after this junction it is called Rio de Panuco, and changes its northern course into an eastern one. Five miles above Panuco, a ledge of rocks runs across the river, which, except in the rainy season, has only four feet water on it, and thus prevents large vessels from ascending it farther. Schooners therefore can only sail as far as Panuco, which is 80 miles by water and about 40 miles by land from the sea. The course of the river

below Panuco is exceedingly winding. It traverses a low and frequently swampy tract, covered with extensive forests, in which mahogany and different kinds of dye-wood are cut. At its mouth the river forms the harbour of Tampico. Its whole course, including the windings, can hardly be less than 400 miles.

The climate of these table-lands varies in proportion to their elevation above the sea. In those of Tenochtitlan and Tlascala, which are nearly equal in this respect, the mean annual temperature is 62°. In winter the thermometer generally ranges between 45° and 47°, and sometimes, though rarely, descends below 32°. In summer it never exceeds 75° in the shade. On the table-land of Toluca, which is the most elevated, the air is so cold during the greatest part of the day, that the thermometer generally varies between 42° and 46°, and even persons who have been brought up in northern regions find the climate very unpleasant. On the table-land of Valladolid, Mixtecapan, and Michoacan, which are considerably lower than Tenochtitlan, the mean annual temperature probably varies between 66° and 68°. All these countries, being more than 5000 feet above the sea-level, are called by the inhabitants *Tierras Frias* (cold countries). The winter is indeed not severe, but the summers are not warm. To the small difference of the temperature in the different seasons, and to the want of sufficient heat in summer, is to be attributed the fact that several plants do not grow in these countries, which thrive very well without the tropics and in places the mean annual temperature of which is considerably below that of the table-lands.

The seasons on the table-lands are only two, that of the rains (*estacion de las aguas*) and the dry season, or summer (*el estio*). The rains commence in June or July, and terminate in September or October; the rainy season consequently lasts only four months. The rains occur earlier in the countries approaching the eastern shores, and extend afterwards farther west. They are accompanied by thunderstorms, which are experienced successively at Mexico, Guadalajara, and on the western shores. We are not acquainted with the quantity of rain which falls on any of the table-lands, but it is probably much less than that which falls on the low shores of the adjacent seas. The greatest quantity appears to fall along the range of the Sierra Madre and its branches. It would also seem that the table-lands which approach the Pacific have more abundant rains than those lying nearer the Gulf of Mexico. The table-land of Mixtecapan seems particularly favoured in this respect, as the rains begin in the month of May, and always continue to October; they are also more abundant. Though the rains are much less abundant on the table-lands than on the coast, they would be sufficient to maintain a vigorous vegetation, but for the rapid evaporation. To this must be added the peculiar nature of the soil, which covers rocks of a porous nature, by which the moisture is absorbed and carried too far below the surface; consequently all these table-lands have rather an arid soil, which can only be employed in the cultivation of grain where it can be watered; and even many of the rivers disappear in fissures of the rocks. The plains are entirely destitute of trees, but are covered with several kinds of cactus, a plant which grows best on an arid soil, and endures a considerable degree of cold. Forests of trees occur only on the hills and short ranges, which in several places are dispersed over the plains, and especially on their western declivities: the eastern declivities generally present bare rocks. For want of the means of irrigation, perhaps nine-tenths of the table-lands are only used as pasture, and the grass is sufficient for that purpose to the months of March and April, when the south-east wind, called *viento de la Mistica*, begins to prevail, which, being very dry and hot, withers the smaller plants and grass. In this part of the year the country has a very dismal aspect, and the cattle suffer much where there are no pasture-grounds that can be irrigated, until the beginning of the rainy season, when the surface of the ground is suddenly changed. The elevated table-lands of Mexico, like those of Tibet and Central Asia, which are still more arid, have also a large portion of their surface covered with muriate of soda and other saline substances, in the dry season, like a hoar-frost, which considerably diminish the productive powers of the soil.

The countries which are elevated from 2500 to 4000 feet above the sea-level, such as the broken region lying between the table-lands of Tenochtitlan, and Toluca and Michoacan on one side, and between the table-land of Mixtecapan on the

other, and the uneven plain of Xalisco, are called *Tierras Templadas*. Their mean annual temperature amounts to between 75° and 78°, and they enjoy nearly a continual spring, as the difference of the temperature in the colder and hotter season does not exceed 8°, or at the utmost 10°. These tracts produce the tropical fruits and the sugar-cane in abundance; and, as well as the table-lands themselves, enjoy a very healthy climate all the year round, whilst the inhabitants of the low tracts along the coast are subject to dangerous diseases.

We pass to the countries lying to the north and east of the Sierra Madre. The country, which is bordered by this range on the south and west, is a plain of great length, terminating on the north on the banks of the Rio del Norte, between 30° and 32° N. lat., and at the Sierra de las Espuelas, the most northern offset of the Sierra Madre. Its length is nearly 700 miles. Its width, which between 22° and 24° N. lat. hardly exceeds 100 miles, widens considerably farther north, so that at 29° N. lat. it is probably more than 300 miles. The southern portion of this plain, as far north as a line drawn from Zacatecas on the west to Catorce on the east, may be on an average about 6000 feet above the sea-level. Its surface is in many places traversed by ranges of hills, running east and west, and its soil in general resembles that of the plain of Queretaro, but is not equal to it in fertility, a great portion of it being covered with sand, and other parts with stones. Some districts, being possessed of the means of irrigating the land, are distinguished by fertility, as the country about S. Luis de Potosí, and the Valle del Maiz, which lies on the banks of the Rio Tamolin, a tributary of the Rio Panuco. A great portion of the country serves as pasture-ground for numerous herds of cattle, sheep, and goats. The rains are less abundant than farther south, and fall mostly in October and November; the heat in summer is less and the cold in winter greater than on the table-land of Queretaro.

The northern portion of the plain is still less favoured by nature. Near a line drawn from Zacatecas to Catorce it is about 6000 feet above the sea-level, but in the neighbourhood of the Rio del Norte probably not more than 3000 feet. It suffers greatly from the scarcity of rain, which in the southern districts is far from being abundant, and north of 27° N. lat. is very rare. It is consequently badly supplied with water, the springs being few in number, and the water of a very disagreeable taste. This latter circumstance is principally owing to the soil, which contains a great portion of carbonate of soda. The plain contains numerous dry salt-lakes, whence large quantities of carbonate of soda are collected and taken to different parts of the republic for the manufacture of soap. All the rivers which water this plain rise along the eastern declivity of the Sierra Madre, and running northward, are lost in some lake having no communication with the sea, with the exception of the Rio Conchos, which rises with several branches between 26° and 28° N. lat., and falls into the Rio del Norte near 31° N. lat. In the southern districts are the Rio Grande de las Nieves, which runs about 300 miles, and loses itself in the lake of Parras, and the Rio Nasas, which after a course of about 200 miles enters the lake of Mapimi. In the northern districts are the Rio de S. Buenaventura, and the Rio de las Casas Grandes, which run hardly more than 100 miles, and fall into the lakes of S. Maria and of Guzman. The cultivable land of this plain is limited to the river bottoms, which extend from two to four miles along the banks, and produce Indian corn and other grain. In the valley of the Rio Nasas much cotton is grown, and in the neighbourhood of the lake of Parras are extensive vineyards, from which a good wine is obtained. All the extensive tracts which separate the river bottoms from one another are level, and consist mostly of a firm soil, the sandy or stony tract being rare and of comparatively small extent; but they are quite destitute of wood or even shrubs, and in certain seasons even dry grass is rare. Gales of wind are very frequent, and from whatever point of the compass they blow, they are very cold and raise immense clouds of dust filled with saline particles. The last-mentioned circumstance is considered as the cause of the insalubrity of this region. Within this plain is situated a mountainous region, called the *Bolson di Mapimi*, which occupies the tract of land extending from the northern shores of the lake of Mapimi to the banks of the great southern bend of the Rio del Norte. But its extent to the east and west is imperfectly known. It is in possession of an unsubdued

tribe of natives, called the Appaches, and has never been examined by European travellers, but it is said to contain an abundance of metals, which have never been worked.

The Sierra Madre, which extends along the western side of this plain in a north-western direction, lowers towards it with a gradual descent, or, more probably, in terraces, separated from each other by abrupt declivities, and traversed by deep and steep transverse valleys. The crest of the chain is situated towards its western declivity, and between the ridges which compose the mountain-region are longitudinal valleys, narrow, but of considerable extent, which contain rich mines. Towards the plains, which lie along the Pacific, the descent is very rapid, and only furrowed by ravines.

The country between the Sierra Madre and the Pacific is naturally divided into two different regions, the plains of Cinaloa and the hilly region of Sonora. The former extends between 24° and 28° N. lat., and the latter between 28° and 32° N. lat. The plains are perfectly level, and only hills of moderate elevation divide them from the Sierra Madre. Their soil consists of a sandy clay, almost without a pebble, which is fertile wherever it is irrigated; but as this country has not been in possession of the Spaniards much more than a century, agriculture has not yet made much progress. The rains set in regularly on the 24th of June, and last about two months. The greatest heat is experienced before the rains, from the month of March, when the country is parched up and resembles a desert. The rivers running across the plain flow in beds considerably below its surface, and it does not appear that even after the most abundant rains they rise high enough to water the adjacent tracts. The most considerable of these rivers are the Rio de Culiacan, the Rio del Fuerte, and the Rio Mayo, each of which may run upward of 100 miles in a wide and deep bed. The greater part of the plain seems to be considerably elevated above the sea, as there is a sensible descent some miles in length from it to the low and sandy tracts which skirt the shore.

Sonora, which begins at some distance north of the Rio Mayo, has likewise a tract of level and low land along the sea, but it soon rises to some elevation, and then extends nearly on a level many miles inland. This part of the country is rather sterile, but more from want of moisture than from want of good soil, which resembles in every respect that of the plain of Cinaloa. The hilly country begins from 30 to 40 miles from the shore, and is traversed by several ridges running south and north, parallel to the Sierra Madre. It is not yet known how they are connected with the principal mountain-chain. In some places the hills rise to the height of mountains, but their elevation has not been ascertained. Between these hills run rivers in valleys, generally several miles wide, and possessed of a considerable degree of fertility. The largest is the river Yaqui, which is formed by two branches; the Rio Babispe, flowing along the base of the Sierra Madre southward, and the Rio Oposura, which runs parallel to it farther west. The first runs about 200 miles, and the second 120 miles, before they unite upon emerging from the hilly region. After their junction they take the name of Rio Yaqui, and flow about 150 miles more, until they fall into the Gulf of California, south of 25° N. lat. The central districts of Sonora are also traversed from north to south by the rivers Arispe and Dolores, which flow parallel to each other until they unite a few miles above the town of Pitic at S. Jaunitz; a few miles below Pitic the united river enters a lake of some extent, which has no communication with the sea. The whole course of this river may be about 200 miles. In the north-western corner of Sonora is the Rio de S. Ignacio, which runs more than 100 miles, and is likewise lost in a lake. None of these rivers are navigated, but they are used to irrigate the valleys, in which maize and wheat are grown to a considerable extent. Without this irrigation the country would be a desert, as the rains, which come in September, do not last more than four weeks, fall only in short showers, and are very irregular and uncertain. It would seem that in the most northern district there is no rain at all. As this part of the Mexican States is situated within the temperate zone, it partakes of the great changes in temperature which commonly occur in these countries. The thermometer ranges during the year between 30° and 95° . During the northern and north-eastern winds, which blow from the Rocky Mountains, and probably pass over elevated plains, it sometimes freezes every night for several weeks

at Pitic (29° N. lat.), and the thermometer then sinks as low as 18° in the night-time. It seems that frost occurs in these parts every year. But the summer is excessively hot, and the hot weather continues for several months: the rains take place much later here than farther south.

The countries hitherto described are situated on the Mexican isthmus, which is divided from the main body of North America by a plain extending from the shores of the Pacific eastward to the lower course of the Rio del Norte, between 32° and 33° N. lat. This plain seems to be interrupted by two mountain-groups only: one of them, the Arizona, is situated near 109° W. long., and noted for the fabulous stories of its great wealth in the precious metals; the other occurs near the bank of the Rio del Norte, where the river begins to flow in a south-south-eastern direction, and is called Sierra del Florido. Nothing is known of these mountain-groups. The plain is drained by the river Gila, which runs more than 500 miles in a western direction, and unites with the Rio Colorado near its embouchure in the Gulf of California. It rises in the Sierra de Mogollon, the most southern extremity of the principal range of the Rocky Mountains; and though it may have a considerable volume of water in its upper course, it loses it imperceptibly by flowing through an arid plain of great extent, in which not a drop of rain falls during the whole year, and in which it does not seem to be joined by any tributary of importance. The plain itself is a desert, in which only a few families of the Appaches lead a wandering life. An exception however is to be made in favour of the district where the extensive ruins called Casas Grandes (near 110°) are found, as such ruins generally occur in spots favoured by natural fertility.

The Mexican States extend much beyond this natural boundary, and comprehend a considerable portion of the mainland of North America, namely, the two Californias; the unknown region extending between Upper California and the Rocky Mountains; the Vale of the Rio del Norte, or New Mexico; and Texas, or the country extending east of the Rocky Mountains to the boundary-line of the United States of America. As to the Californias, see CALIFORNIA, vol. vi., p. 158. Of the country lying north and east of Upper California little is known: two lakes of great extent are stated to occur in it, of which one is said to be salt. The reports of the monks respecting this wide tract are mentioned in the article COLORADO. We shall conclude our survey with New Mexico and Texas.

New Mexico is a valley of great extent, included by the two mountain-ranges with which the Rocky Mountains terminate on the south. The western range, called Sierra de Mogollon, commences about 34° N. lat., and is in the plain which lies along the upper course of the Rio Gila. It is not known if this range is connected with the Sierra del Florido, which is about 80 miles south-south-east of it. The other range, called Sierra del Sacramento, rises farther east, opposite the mountain-region called the Bolson de Mapimi, in the most southern bend of the Rio del Norte, near 29° N. lat., and extends northward to 40° N. lat., where it joins the Sierra de Mogollon. Both ranges run nearly parallel to one another, from 34° to 40° N. lat., and the long longitudinal valley between them is New Mexico. Its southern district, between 34° and $35^{\circ} 30'$ N. lat., is a desert, covered with arid hills, which come close up to the banks of the river, and are nearly without vegetation, except in some narrow valleys traversed by rivulets. This district is called Deserto del Muerto. The northern district, between $35^{\circ} 30'$ and 38° N. lat. is a valley, from 20 to 40 miles across: this part has been settled, and produces grain enough for the consumption of the population. But the greatest wealth of the people consists in their pasture-grounds, which feed numerous herds of sheep, their plantations of tobacco, and the wild animals which inhabit the adjacent mountains. The most northern part of the valley, between 38° and 40° N. lat., is uninhabited, probably on account of the severity of the climate, which even in the settled part is so great that the Rio del Norte, though a rapid river, is annually covered with ice for several months. This circumstance is partly to be attributed to the ranges enclosing the valley, which in some places are covered with eternal snow, but chiefly to the elevation of its surface, which Humboldt thinks cannot be less than from 2000 to 2500 feet, an estimate probably rather below than above the truth. Rain is very scarce and usually falls only once a year, and in some years not at all; the snow however, which covers the ranges to th

month of June, supplies the soil with the moisture requisite for the growth of grain and grass.

The Rio del Norte, also called in its lower course Rio Grande, and on the maps incorrectly Rio Bravo, is the largest of the rivers of Mexico. Humboldt estimates its course at nearly 1400 miles. It rises in the most northern angle of the Vale of New Mexico, near 40° N. lat., not far from the sources of the Arkansas, a tributary of the Mississippi, and of the Rio Colorado, which falls into the most northern recess of the Gulf of California. The Rio del Norte runs southward from 40° to 29° N. lat., and even in the vale of New Mexico is a considerable river, which has water enough for small boats, but is not navigated. In the mountains between 35° 30' and 34° N. lat. it seems to be too full of rapids to permit of any kind of navigation. Where it enters the plain, south of 34° N. lat., its waters are abundantly used for irrigating the fertile district which surrounds the Passo del Norte, and its water is considerably diminished. Afterwards it receives a small supply of water by the Rio Conchos; and after having changed its course by a great bend to the east and north-east, it receives a larger supply by the Rio Puerco, which runs in a longitudinal valley east of the Sierra de Sacramento; but as its course lies through an arid plain, which is rarely refreshed by abundant rains, the volume of its waters is too small even for small craft, until it has changed its course to the south-east, and has arrived at the Presidio de Rio Grande, about 200 miles from its mouth. At this place or in its neighbourhood, as it seems, the river leaves the elevated plain and descends into the lower country which extends along the shores of the Gulf of Mexico, and from this place downward it may be navigated by small boats. The waters of the Rio del Norte rise, as those of many other rivers, annually: this rise begins in the month of April, is highest in May, and at the end of June the waters attain their greatest height. This change is owing to the melting of the snow on the surrounding mountains. The rise of the water is not perceptible in the lower course of the river. The mouth of the river is south of 26° N. lat., at Braxos de Santiago, and about twenty miles below Matamoros, to which towr vessels of small burden may ascend: but larger ones cannot enter the river on account of its bar and of numerous shoals.

The country east of the Sierra del Sacramento, and north of the lower course of the Rio del Norte, which is comprehended almost entirely under the name of Texas, differs greatly in its natural features from all other parts of the Mexican States. That portion of it which lies along the Sierra del Sacramento and extends eastward to 102° W. long. is considerably elevated above the sea, probably not less than 2000 feet. Its northern portion, embracing the country on both sides of the Red River as far north as the Arkansas, is an extensive plain, considerably elevated above the watercourses, along the course of which are bottoms of moderate extent, covered with trees of heavy growth, which indicate a considerable fertility of the soil; but the spaces between these river-valleys have an arid though commonly a firm soil, which is covered with vegetation only in the early season of the year, and on the approach of summer is deprived of it. Like the extensive plains along the base of the Rocky Mountains, it wants water and wood, and seems to be incapable of cultivation. This region is joined on the south by an extensive tract of mountainous country, called the hills of San Saba, which is connected with the Sierra del Sacramento, and extends southward to the mouth of the Rio Puerco. Its eastern offsets extend to the meridian of 100°. The mountains probably do not rise above their base more than 2000 feet; but this is only a supposition, as the whole region, being in possession of a tribe of natives, the Comanches, who are enemies to the white settlers, is unknown. In this mountain-tract most of the large rivers that water Texas take their origin. Between this region and the elevated plain on the Red River a salt swamp of great extent is stated to exist, in which one of the branches of the Rio Brazos rises. When the salt, which crystallizes on its surface after long dry weather, is dissolved by abundant rains, the water of the Rio Brazos becomes brackish.

The remainder of Texas, included between the meridian of 100° N. lat., the Red River on the north, the Sabine on the east, and the Gulf of Mexico and Rio del Norte on the south, is considered one of the most fertile countries of North America. The coast is low, and skirted by a number of long flat islands, separated from the main by narrow

straits; but these straits are much deeper than those further south, and afford in several places good anchoring ground for vessels of moderate size; so that Texas has more and better harbours than all the Mexican States on the Gulf of Mexico taken together. The bars on the rivers have deeper water on them, probably because their course is less rapid and their waters less troubled, as they do not descend from countries at a great elevation above the sea-level.

The low country along the coast extends about ten or twelve miles inland; it is not, like the country south of the Rio del Norte, a sandy desert without vegetation, but suffers rather from superabundance of water, being a great part of the year inundated or in the condition of a swamp. Behind this low swampy tract the country rises imperceptibly for some miles, and then appears to stretch out in a wide plain with a nearly level surface. The width of this plain varies considerably, as its northern and western borders form nearly a crescent. Near the boundary-line of Louisiana it is from 40 to 50 miles wide. At the north-western corner of the Gulf of Mexico, between the rivers Trinidad and Guadalupe, its width is stated to be 70 or 80 miles; but on approaching the Rio del Norte it narrows to 20 or 25. This plain is from 10 to 30 feet above the watercourses, and with the exception of the low bottoms along the banks of the rivers, it is not subject to inundation. The tide, though it varies only from two to three feet, ascends the rivers to the distance of 45 or 50 miles from the sea in a straight line. The whole of this plain is wooded, with the exception of the highest tracts of land between the rivers, which are destitute of trees, and exhibit fine prairies. The forests consist of different kinds of oak, hickory, iron-wood, sugar-maple, and other useful trees, which are found in the southern states of the American Union. It is supposed that the whole of this tract might be cultivated and changed into an immense field, producing cotton, sugar, Indian corn, tobacco, wheat, and every kind of plants and fruit-trees which grow in the temperate zone and on the borders of the tropics, whilst the prairies, which hardly occupy one-fifth or sixth of the region, would, in their natural state, serve as pasture-ground for cattle.

The country at the back of this plain is less favoured by nature, the proportion between the cultivable land and the prairies being nearly inverted. The former is chiefly limited to the bottoms of the rivers, which are numerous, and generally wide, so that they perhaps occupy one-fourth of the surface. Their soil is alluvial, and in the present state covered with trees of large growth, a certain indication of great fertility. As the rivers are not impeded in their course, and have sufficient fall to draw off the superabundance rapidly, the inundations are of short duration, and serve only to impart new vigour to the soil. The country between these bottoms generally rises from them with a gentle acclivity to an elevation of 200 to 400 feet, and presents for the most part an undulating surface, on which isolated hills of moderate elevation are dispersed. By far the greatest part of this tract is destitute of trees, which occur only in isolated clumps, and at considerable distances from one another. The most extensive of these wooded islands cover the bases and declivities of the hills. The remainder of the country is covered with grass, which affords excellent pasture. As the grass maintains its verdure for many months, it appears that the soil is less arid and destitute of moisture than farther north, or on the table-lands of Mexico, and it is thought that extensive tracts of it may be cultivated with wheat or other grains. The least fertile district of this tract occurs about the sources of the Sabine river, where the country rises into hills, covered with a light sandy soil and overgrown with pine-forests. It resembles that part of Louisiana which lies between the Red River and Arkansas west of Natchitoches.

Texas owes its great capability for agricultural purposes to its numerous rivers and the regularity of their course. These rivers, when the country shall be well settled and cultivated, will materially contribute to its prosperity, as all of them, even those which run only fifty miles, are navigable for small craft in the greatest part of their course. The most remarkable of these rivers from west to east are—the Rio Nueces, which flows about 250 miles with a general south-eastern course; the Rio Guadalupe, which is nearly as long, and which falls into a lagoon forming the harbour of Espiritu Santo; the Colorado, which traverses in its upper course the mountain-tract of San Saba, flows upwards of 400

miles, and falls into the lagoon constituting the harbour of Matagorda; the Rio Brazos, or Brazos de Dios, whose origin is near to that of the Red River, and which, flowing chiefly in a south-south-easterly direction, intersects nearly the centre of Texas and the most fertile districts. It enters the sea after a course of more than 400 miles, forming at its mouth a harbour, with a bar on which only from three and a half to five and a half feet of water are found. The Rio Trinidad, after a course of more than 300 miles in a south-south-easterly direction through a very fertile tract, falls into Galveston Bay. As to the Red River and Sabine River, which separate Texas from the United States of North America, see LOUISIANA.

Productions.—As there is so great a difference in the climate of the different regions of Mexico, there must be a corresponding variety in their productions. Humboldt asserts that within these states almost all the vegetable productions may be grown which are found between the equator and the polar circle. The agricultural productions which actually are grown prove the justice of this observation. On the highest of the table-lands, that of Toluca (9000 feet) wheat does not succeed, nor does it succeed in Europe beyond 60° N. lat. On this table-land agriculture is limited to the cultivation of barley and the plantations of the American aloe, which may be considered as the vineyards of Mexico, the juice of this plant being converted into a kind of wine, called *pulque*. [AGAVE.] It is however remarkable that Indian corn grows on this table-land, a circumstance which shows the difference in the climate of countries which have a great elevation above the sea, and those in which it depends on geographical position only. Most of the table-lands however are from 6000 to 7500 feet above the sea; and as their climate may be compared with that of the southern countries of Europe, we find that they produce all the cerealia of Europe, with the exception of oats, which are not used, as horses in Mexico are fed on barley. The fruits also are those of Europe, as cherries, peaches, plums, apricots, apples, pears, figs, and pomegranates. The vegetables too are those of Europe, among which capsicum, called *chile*, is most abundantly grown, as it is used all over the country nearly as salt is in Europe. The plantations of American aloes on these table-lands are also very extensive. The difference between the agricultural productions of the Tierras Templadas and Calientes is not well established. Maize is grown everywhere, and constitutes the principal food of the lower classes; and it is the only grain which is cultivated for food, rice being only grown to a small extent in the wet countries along the Rio Huasacualco. But the plantations of plantains and those of manioc are extensive; and besides these, *Oxalis tuberosa*, *Dioscorea alata*, and batatas are cultivated on a large scale. Oranges and lemons, which do not succeed on the table-land, are abundant in the Tierra Templadas; and besides these, many fruits of hot countries, especially pine-apples, guavas, and others.

The agriculture of the table-lands does not supply any article for exportation. Cotton is grown along the shores of the Pacific, and in the valley of the Rio Nasas, in a deep depression of the northern table-land; and coffee on the eastern coast, west of the town of Vera Cruz; sugar is cultivated in many places, and a considerable quantity is exported; cocoa is collected in the low country along the river Huasacualco; and indigo along the southern coast, but only for home consumption. Tobacco, which in many parts succeeds very well, is only permitted to be grown in certain places, as government, which derives a considerable income from a heavy duty laid on its consumption, has limited the cultivation to certain spots to prevent all evasion of the tax. Three plants grow wild in the forests, at the base of the steep ascent which divides the low eastern coast from the table-lands, and supply articles of export—the jalapa, sarsaparilla, and the vanilla.

All the domestic animals, which have been brought over from Europe by the Spaniards, have multiplied greatly in Mexico, owing to the wide tracts which are not or cannot be cultivated, and which afford pasture-ground for nine or ten months of the year. Cattle is abundant, both on the table-lands and the lower tracts; among the latter, especially on the wet plain of Tabasco and the arid plain of Yucatan. Jerked beef and horns are exported. Sheep are numerous on the table-lands, especially on the northern, which are much drier; and wool is an article of exportation. Horses abound generally, and in the north-eastern provinces a great number are found in a wild state: they

are easily taken and broken in. Horses and mules are exported in great numbers to the United States. On the great plains bordering on the Red River and Arkansas the American buffalo abounds. In winter the buffaloes traverse the hills of San Saba, and pasture on the plains along the lower course of the Rio del Norte. Carnivorous wild animals are not numerous. Game is abundant, especially deer and hares. Among the birds are various kinds of parrots, mackaws, and humming-birds. The lakes abound in fish. Bees seem to abound on the peninsula of Yucatan, and the cochineal insect is reared with great care on the table-land of Mixtecapan, whence by far the greatest part is brought to the market of the world. In the Gulf of California pearl shells are found, and formerly many pearls were collected, but it seems that this branch of industry has declined.

Mexico is noted for its mines of gold and silver. The gold-mines occur chiefly on the western side of the Sierra Madre, north of 24° N. lat.: the silver-mines are richest on the mountains which rise on the table-lands, and in those which border their margin. During the civil war, which began in 1810 and lasted for many years, the greatest part of the mines were neglected. Their working was however renewed in 1825, chiefly by the English mining companies which sprung up about that time. Before that event (from 1810 to 1825), the produce was much less than it had been before 1810. Since the year 1825 it has considerably increased, though not so much as was expected. Besides the precious metals, Mexico has abundance of copper, iron, and lead, which are worked. The iron-mines however have only been opened since the year 1825. A quicksilver-mine is worked at S. Onofre, on the northern declivity of the Sierra Madre, in the state of Queretaro. Tin is also stated to exist. The carbonate of soda, called *tequesquite*, which is necessary for the smelting of the silver ore, is collected in several lakes, where it is found crystallized on the surface in great abundance. It is also common in most places of the table-land in the upper layers of the soil, where it appears in the state of an efflorescence in the month of October, after the rains have ceased.

Inhabitants.—The population of these states is composed of creoles or descendants of Europeans, of Indians or natives, and of those of mixed blood. The number of Europeans, who are called *Gachupines*, and formerly amounted to 80,000 individuals, has been much reduced by the expulsion of the natives of Spain; and though many individuals of other nations, especially Englishmen, have settled in these states during the last twenty years, it is supposed that the whole number of Europeans hardly amounts to more than 20,000 or 25,000.

The bulk of the population still consists of the descendants of those nations which inhabited the country at the time of the Spanish invasion. Humboldt thought that they constituted two-fifths of the whole population; but as he asserts that no natives were mixed up with the white population in Sonora, where modern travellers have found that they really constituted more than half the number of the inhabitants, it is probable that the natives form one-half of the whole population, especially if we take into the account the numerous tribes which occupy the large tract of unknown country between Upper California and the vale of the Rio del Norte, and which are computed to amount to 300,000 individuals; though this number is probably exaggerated.

The aboriginal tribes of America resemble one another in the principal features of their face and body, which, according to Humboldt, are the following: the colour of their skin approaches that of copper; their hair is black, lank, and so smooth, that it always appears as if it had been wetted; and they have little beard. Their figure is rather short and stout; their eyes small, long, and a little raised towards the temple-bones, as in the tribes which belong to the Mongol race. Their cheek-bones are prominent, their lips thick, and their mouths exhibit an expression of softness, which forms a strange contrast with the rigidity of their looks. Though they thus greatly resemble one another in personal appearance, the tribes into which they are divided speak languages which are said to differ as far from each other as the English from the Russian. Humboldt states that twenty languages of this description were spoken within the territories of the states south of 33° N. lat.; but it would seem that he has not comprehended in this number the eight nations which live

within the boundary of Sonora, or the northern portion of the state of Occidente. The number of tribes which are still entirely independent, and live north of 33° N. lat., is not known, and seems to be very great. The language which is most extensively spoken is that of the Azteks, which seems to be understood by nearly all the tribes which inhabit the country between 18° and 23° N. lat. The language of the Otomites, which is spoken in the countries along the Pacific between 20° and 24° N. lat., is remarkable for its structure, which resembles that of the Chinese language, being composed of monosyllables. (Naxera, *De Lingua Othomitorum Dissertatio*, Philad., 1835, and *London Geographical Journal*.) Next to the language of the Azteks, that of the Otomites is the most widely spread.

The natives who have submitted to the dominion of foreigners have attained different degrees of civilization. Those who inhabit the country between 18° and 23° N. lat. were, on the arrival of the Spaniards, subjects to the kings of Tenochtitlan and Michoacan, or united in the republics of Tlaxcallan (Tlascala), Huexochingo, and Chollollan, and had then attained a considerable degree of civilization, as is proved by the ruins of their religious buildings, or *teocallis*, their causeways and dikes, their hieroglyphics, paintings, and sculptures; and though the objects of their agriculture were only few in number, their cultivation was extensive, and carried on with considerable care. They submitted to the conquerors, and continued to cultivate the ground on which they were born. Their present condition is not worse than that of the lower classes who cultivate the ground in most parts of the European continent, but they appear to have fewer wants, and accordingly indulge more in indolence. Among them are some very rich families, but they are not distinguished by their mode of life or their dwellings from the other members of their tribe. In most places they live mixed with the whites and metis; in others they occupy large tracts, to the exclusion of all foreigners. The countries north of 24° N. lat. were inhabited at the time of the conquest by tribes resembling those of the United States of North America. They had no fixed dwellings, and lived mostly on the produce of the chase; and as this produce could not be abundant in countries whose vegetation is so scanty, and which are destitute of trees, their numbers were small, and they speedily retired from the large plain east of the Sierra Madre to the mountain tract called the Bolson de Mapimi, where they still continue their savage life. They have also disappeared from the plain which extends along the Pacific to the Rio Mayo. In these two plains a few natives are only found along the southern boundary-line, and these seem to have settled there since the conquest. But in the hilly tract north of the Rio Mayo the natives resisted the invasion of the Spaniards, and were only subjected by the Jesuit missionaries. The padres accustomed them to a civilised life, and taught them the principal mechanic arts: their success here was hardly inferior to that which they had in the famous missions of Paraguay. Though these Indians inhabit the same country with the numerous white families which have spread among them, they live in separate places, and no close intercourse exists between them, except for the purposes of trade. In the arts of domestic life they seem to approach nearer to the Europeans than the Azteks, and they certainly exhibit a greater degree of energy and mental power than the last-mentioned nation.

The *Indios Bravos*, or savage tribes, inhabit the countries north of 33° N. lat., along the Rio Gila, the Bolson de Mapimi, the mountain-ranges which include the vale of the Rio del Norte and the north-western district of Texas. Many of them, especially the Appaches and Comanches, the most numerous of the tribes, were and still are at open war with the white settlers. For the protection of the latter the Spaniards erected presidios: a presidio consists of a wooden wall of a quadrangular form, within which the houses are built, and the gates are shut at sunset. They are inhabited by a few white families and a small number of soldiers for their protection. The inhabitants of the presidios cultivate the adjacent grounds, and keep large flocks of cattle and sheep, but do not venture to pass the night without the walls. The *Indios Bravos* generally live on the produce of the chase, and are most numerous in the tracts which are visited by the buffaloes. It does not seem that they cultivate the ground. Where the states of Yucatan and Tabasco border

on Central America there is still an independent tribe, the Mayas, who speak a language different from that of the Azteks, and have made some progress in civilization: they cultivate maize, cocoa, and tobacco, and clothe themselves with cotton and the bark of the India-rubber trees, but they still depend principally on fishing and hunting for their support.

The mixed race is mostly composed of the descendants of Europeans and the aboriginal tribes: these are called *Metis*, or *Mestizos*, and constitute more than one-fourth of the population. The descendants of Africans and Indians, and of Africans and Europeans, are much fewer. The former are called *Zambos*, and the latter *Mulattos*. In the neighbourhood of Acapulco there are a few Chinese and Malays, who have emigrated from Asia. There are very few negroes in this country.

The whole population, which probably at present considerably exceeds seven millions, is composed of these different elements, according to a rough estimate, in the following proportions:—

Aboriginal nations	.	.	3,500,000
Mestizos	.	.	2,000,000
Mulattos and Zambos	.	.	600,000
Creoles, or descendants of Spaniards	.	.	1,200,000
Europeans	.	.	25,000
			<hr/>
			7,325,000

Political Division and Towns.—The confederation called the United Mexican States consists of nineteen republics or states, besides three territories, and an immense tract of country which has not been annexed to any of them. According to an estimate, the states contain the following number of inhabitants and extent in square miles:—

	Population.	Extent in sq. miles.	Number of Inhabitants on a sq. mile.
1. Chiapa	130,000	38,500	4
2. Yucatán	520,000	48,500	11
3. Tabasco	55,000	10,500	5
4. Oaxaca	600,000	34,500	17
5. Vera Cruz	250,000	22,000	11
6. Puebla	820,000	21,000	39
7. Mexico	1,200,000	30,000	40
8. Michoacan	450,000	26,500	17
9. Xalisco	800,000	74,500	10
10. Guanajuato	450,000	8,600	52
11. Queretaro	230,000	15,500	15
12. S. Luis de Potosi	220,000	17,500	13
13. Zacatecas	275,000	18,500	15
14. Durango	200,000	56,500	4
15. Occidente	180,000	148,000	1½
16. Chihuahua	120,000	72,500	1½
17. Coahuila with Texas	46,000	136,500	½
18. Nuevo Leon	85,000	20,000	4
19. Tamaulipas	60,000	40,000	1½
<hr/>		<hr/>	<hr/>
6,691,000		833,600	8

To these the territories are to be added:—

	Population.	Extent in sq. miles.	Number of Inhabitants on a sq. mile.
1. The territory of Santa Fé, or New Mexico	45,000	45,000	1
2. Territory of Lower California	4,000	30,000	¼
3. Territory of Upper California, comprehending the whole country north of the Rio Gila, and between the Pacific and the mountains, including the vale of Rio del Norte	325,000	600,000	
<hr/>		<hr/>	<hr/>
374,000		675,000	

1. The state of Chiapa, called also *Las Chiapas*, comprehends the whole of the western declivity of the table-land of Guatemala, as far as it belongs to the Mexican States,

and a portion of the plain of Tabasco, the river of that name forming for a considerable distance the boundary-line between Chiapa and Tabasco. Though its soil is in general fertile, and the climate favourable to the growth of tropical productions, it does not appear to contribute any article to commerce, except logwood, which is floated down the rivers Usumasinta and Tabasco to Villa Hermosa. Near the banks of the Rio Chacamas, a tributary of the Usumasinta, are the ruins of Palenque, in a country which at present is a desert overgrown with trees. They are stated to extend for more than twenty miles along the summit of a ridge, and, as far as can be inferred from their architecture, they seem to owe their origin to a people more resembling in taste the Europeans than the Azteks. This state formed a part of Central America up to 1825, when it was united to Mexico, without the republic of Central America having renounced its claims on it. The capital is Ciudad de las Casas, formerly Ciudad Real, in a very fertile country, with about 4000 inhabitants. It has a college for Catholic clergymen, and a monument has been erected here to the famous Las Casas, the protector of the Indians, who was bishop of this province, and died in 1566. Some other places are still more considerable: as Chamula, with 6000 inhabitants; S. Bartolomeo de las Llanos, with 7500 inhabitants; Comitán, with 6000 inhabitants; and Tuxtla, with 4500 inhabitants.

2. The state of Yucatan comprehends the peninsula of that name as far south as 18° N. lat. It exports much campeachy-wood and fustic, which grow mostly on the eastern coast, and also on the western, south of $20^{\circ} 30'$ N. lat., and also a considerable quantity of bees-wax. The Mayas, who live in a state of independence, occupy its southern district. The rivers Champoton and Pacaitun are navigable, for small craft, for many miles inland. The capital is Merida, with 28,000 inhabitants, situated on an arid plain about twenty-five miles from the sea. It carries on a considerable commerce by means of the harbour of Sizál, which is properly only a roadstead formed by a sand-bank called Bajo Sizál, twelve miles long. Farther east is Valladolid, with a population of 3000 inhabitants, in a district in which much cotton is grown. On the eastern coast is Salamanca de Bacalar, with 2000 inhabitants, whence much mahogany and fustic are shipped to Belize. On the western coast is Campeachy [CAMPEACHY], and a number of populous villages inhabited by Indians.

3. The state of Tabasco extends over the greater part of the low plain, from the lake of Terminos on the east, to the Rio de Huasacualco on the west. It is traversed by the Rio de Tabasco. It exports cocoa, coffee, Tabasco pepper, indigo, and vanilla. The capital is Villa Hermosa, also called San Juan Bautista, on the river Tabasco, about fifty miles from the sea, to which place vessels of moderate size may ascend the river. It carries on some commerce, and contains 8000 inhabitants.

4. The state of Oaxaca extends over the whole of the table land of Mixtecapán, and is rich in agricultural products: the industrious inhabitants rear the cochineal-insect and the silkworm, and apply themselves to the cultivation of indigo. It has some mines of gold and silver in the mountain-ridge which separates it from the low plain of Tabasco, but they do not appear to be rich. This state contains several antiquities, among which are the ruins of the palace at Mitla, which differ from the ruins of the edifices erected by the Azteks, and approach in style nearer to those of Greece. They lie on the table-land, 5300 feet above the sea. The capital, Oaxaca, which contains 40,000 inhabitants, is built in a depression of the table-land, 4800 feet above the sea-level. It is well-built, has fine houses, squares, and aqueducts, and contains some manufactures of sugar, chocolate, and silk. Tehuantepec is situated about ten miles from the sea, on a plain on which indigo and cocoa are grown, and salt collected in the lagunes which skirt the sea. It contains about 7000 inhabitants, and carries on some commerce by the harbour called Ventosa, or Tehuantepec Road, which is only an open roadstead, but has good anchorage.

5. The state of Vera Cruz comprehends the whole coast of the Gulf of Mexico, from the river Huasacualco on the south-east, to that of Panuco on the north-west, and, in some parts, extends over the mountains which border the table-lands on that side. Accordingly it exhibits a great variety in climate and vegetation: its most elevated parts

are covered with pine-forests. Within its boundary-line are situated the Peak of Orizava, the Cofre de Perote, and the small volcano of Tuxtla. Its commercial products are sugar, coffee, jalap, sarsaparilla, and vanilla. Tobacco is extensively grown. In the northern districts of this state, in a forest near the village of Papantla, is a pyramid built of hewn blocks of porphyry, which are worked with great care and skill. The capital is Vera Cruz. [VERA CRUZ.] Alvarado, about three miles from the mouth of the Rio Alvarado, is a small town, which however carries on some commerce, its port being good, of sufficient space and depth, and well defended from the winds; but the bar at the entrance of the river does not admit vessels that draw ten feet of water. The harbour of Huasacualco, at the mouth of the Rio Huasacualco, has still less water, and is little frequented. At the most northern extremity of the state is the town of Tampico, or rather Pueblo Viejo de Tampico, built on the border of a large shallow lake, the Laguna de Tamiagua, which communicates with the Rio Panuco near its mouth. It contains about 4000 inhabitants, and is ill-built. It carries on a considerable commerce, which however has lately decreased since the new town, called Pueblo Nuevo de las Tumulipas, has been founded on the northern side of the river, about three miles from it. In the interior of the state are the towns of Cordova and Orizava, built near the base of the steep ascent, each containing about 3000 inhabitants; in their neighbourhood much tobacco and coffee are grown. On a level spot, situated on the steep ascent, is the town of Xalapa, or Jalapa, 4335 feet above the sea-level, in a very beautiful country: it contains 13,000 inhabitants. To this place the merchants of Vera Cruz retire when the vomito prieto is raging along the coast.

6. The state of Puebla comprehends by far the greatest portion of the table-land of Tlascala, and also a considerable portion of the lower but very hilly country, which extends to the Pacific, between the table-land of Mixtecapán and those of Tenochtitlan and Michoacan. It contains the elevated peaks of the Popocatepetl and Istaccihuatl. Near the town of Cholula are three remarkable antiquities. [CHOLULA.] The western and southern districts are fertile and well cultivated. In the country about the capital great quantities of carbonate of soda are collected; but this state does not produce any article for exportation. Puebla, the capital, formerly called Puebla de los Angeles, is built in a well-cultivated plain, on the south side of a hill which is wooded to its summit. The houses are all of stone, large, and commodious. The churches and convents are very numerous, and generally well-built. The cathedral is considered the finest and most magnificent edifice in the whole republic, and very rich. The town contains between 50,000 and 60,000 inhabitants; it has some manufactures of cotton, wool, and earthenware, which however have greatly declined since the commerce of Mexico has been thrown open. Its trade with the neighbourhood is considerable. South-east of it is the town of Tehuacan, which is stated to contain a population of 10,000. North and north-east of Puebla are the towns of Tlascala (4000 inhabitants) and Huamantla (3000), whose inhabitants, with those of the country about it, enjoyed some privileges before the revolution. For a notice of Cholula see CHOLULA.

7. The state of Mexico comprehends the two table-lands of Tenochtitlan and Toluca in all their extent, the north-western part of the table-land of Tlascala, and a considerable part of the lower but much more hilly country, which lies to the south of the two first-mentioned table-lands, and extends from them to the Pacific. The river Bolsas drains its southern districts, and the Rio Santiago rises in the north-western, under the name of Rio de Lerma: not far from the morass, in which it takes its origin, is the Nevado de Toluca. Though nearly all the productions of the tropics, together with those of the temperate zone, might be grown in the different regions belonging to this state, none of its agricultural productions supply an article for exportation; the sugar cultivated in the plain of Cuantla y Amilpas, south of the table-land of Tenochtitlan, and in some other places, to a considerable extent, is consumed in the country. It contains several rich mines of silver. This metal does not appear to occur in the mountains which enclose the table-land of Tenochtitlan, but only in the mountainous district which constitutes the most north-eastern portion of the state, and where the Sierra Madre is connected with the mountains border-

ing the eastern margin of the table-lands. In this district are the mines of Real del Monte, Actopan, and Zimapan: there are also some mines of lead and iron. Another mining district lies south of the table-land of Toluca, the principal mines of which are in the neighbourhood of the small towns of Temascaltepec, Sultepec, Tasco, Huasteco, and Tetela del Rio, of which the three last-mentioned places are at no great distance from the Rio Balsas. Carbonate of soda is collected in the districts surrounding the lakes of Tezcucio and S. Christoval. In the vale of Tenochtitlan are several antiquities. Near the town of Tezcucio are two large Mexican pyramids, or teocallis; and about twenty miles farther north, near the small town of Teotihuacan, is a group of nearly 200 of such pyramids, two of which, erected in honour of the sun and moon respectively, are of great dimensions. On the mountainous descent by which the road leads from Tenochtitlan to the Pacific, near the town of Cuernavaca, are some remarkable ruins, which seem to have been a fortress; they are called the fortress of Xochialco. For the description of the federal capital, see MEXICO. The capital of the state is Tezcucio, situated on the eastern border of the lake of that name, whose waters formerly approached the town, but are now about three miles from it. It is a small place, but has much increased since it has been made the capital of the state; it contains above 5000 inhabitants, and some manufactures of cotton. Chalco, with 3000 inhabitants, lies at the eastern extremity of the lake of Chalco. Toluca, with 12,000 inhabitants, ten miles north of the Nevado de Toluca, has a fine cathedral, and is well built. Zimapan, a considerable place, with 9000 inhabitants, is situated in the centre of the northern mining district. This state has two harbours on the Pacific, Acapulco [ACAPULCO], and Zacatula, at the mouth of the river Balsas, but they are little frequented.

8. The state of Michoacan extends over the whole of the table-land of Michoacan and the low country lying between it and the Pacific; a portion of the hilly country south of both these districts also belongs to this state. The river Santiago traverses its north-eastern districts, and within its territories are the lake of Patzcuaro, the peak of Tancitaro, and the volcano of Xorullo. Its productions are various, but no article of export is supplied, except from the mines, which are situated along the eastern border of the state, in the mountain-range which runs between the table-lands of Toluca and Michoacan. The richest mines are near Tlalpujahua, Agangeo, and Zitaquaro. In the districts along the northern boundary-line carbonate of soda is collected, especially in the valley of Ystan, which is enclosed by hills, and situated on the descent from the table-land of Michoacan to that of Jalisco. In this valley are many hundred wells of hot water, of all forms and sizes, from a hole not larger than an inch, to ponds several yards in diameter: in some of them the temperature varies only from 110° to 130°, but in the greater number the water is in a state of constant ebullition. The capital of the state is Valladolid, at present called Morelia, in honour of general Moréles, a large town, with more than 25,000 inhabitants. It consists of one principal street, which is wide and straight, and several lanes. The chief square is spacious; and on its eastern side stands the cathedral, a fine building, which is loaded with ornaments, but they are tastefully arranged. The town is well supplied with water by an aqueduct, erected in later times, at the expense of the bishops, whose side here. Patzcuaro, containing 6000 inhabitants, is built near the lake of that name, at whose northern extremity is the town of Tzintzontzan, with 2500, formerly the capital of the kingdom of Michoacan. In the northern districts of the state are Zamora, with 6000 inhabitants, and Oaxaca, a considerable place, on the banks of an extensive lake. Tlalpujahua, in the principal mining district, has 9000 inhabitants. This state has only one harbour, that of Manzanillo, which is little frequented.

9. The state of Jalisco comprehends the whole of the hilly region of Jalisco, and the lower country between it and the Pacific; its eastern districts extend over the hills which form the ascent to the table-land of Queretaro, and comprise also a small portion of that plain. Within its territories are the lake of Chapala, and the lower course of the Rio Santiago, from its efflux out of the lake to its mouth. The productions are as various as in all those states which are so diversified in climate; but it supplies for exportation only a small quantity of cotton and some cochineal. The mines are not important, with the exception of those of Bola-

ños. Carbonate of soda is collected in some places along the eastern border, and salt is made along the coast. At the south-eastern extremity of the state, in the district of Colima, is the volcano of Colima. The capital of the state is Guadalajara, with 60,000 inhabitants. [GUADALAJARA.] The second place in importance is Lagos, near the eastern boundary, on the table-land of Queretaro, which contains 15,000 inhabitants, and is well built. Farther west is S. Juan de los Lagos, nearly as large a town, built in a deep barranca, and noted for its annual fair, which is held in the month of December. The town of Tepic is situated in a small plain, surrounded by volcanic hills, and considerably elevated above the Rio Santiago, which flows at some distance north of it. It is rather well built, contains 7000 inhabitants, and is forty miles from San Blas, which is its port. Between it and the town of Guadalajara is a difficult mountain-pass, through the barranca of Michetiltic, and the populous town of Tequila. San Blas, the principal port of the state, is on the top of a rock a hundred and fifty feet high, which is precipitous on three sides, and very steep on the fourth: it rises out of a low swampy plain, which in the rainy season is completely under water. At this season the place is unhealthy; and the inhabitants, amounting to 3000, remove to Tepic. The harbour has good anchorage, but is not sheltered against south-western winds. The rocky islands called Tres Marias lie off this harbour. South of Cape Corrientes are the two small harbours of Navidad and Guatlan, which are little frequented. The low country surrounding the Volcano de Colima constitutes a separate district, which is under the general government. This district contains about 150,000 inhabitants, and much cotton is grown in it.

10. The state of Guanajuato comprehends the western districts of the table-land of Queretaro, a part of the Sierra Madre, and a tract north of that range. A range which issues from the mountain-chain of the Sierra Madre traverses the plain in a southern direction, terminating south of the town of Guanajuato. The widest and most fertile part of the Baxio lies within the territory of this state, which exports great quantities of wheat and Indian corn to other states. Rich mines surround the town of Guanajuato. Besides the capital [GUANAJUATO], it contains several populous places. In the Baxio are—Zelaya, with 10,000 inhabitants, and a fine cathedral; Salamanca, with 15,000 inhabitants; Irapuato, with 16,000 inhabitants, and manufactures of cotton; and Villa de Leon, with between 25,000 and 30,000 souls. In the last-mentioned town are considerable manufactures of cutlery and saddlery. San Felipe, in a wide valley between two branches of the Sierra Madre, was formerly a considerable town, but is now in ruins. S. Miguel el Grande has 16,000 inhabitants, and manufactures of cotton and iron.

11. The state of Queretaro extends over the eastern portion of the table-land of Queretaro, and over a considerable part of the plain north of the Sierra Madre. It contains numerous and extensive fertile tracts, and a portion of the Baxio. It has some productive silver mines, which lie near its eastern boundary-line, along the river Moctezuma or Panuco, in the district of Cadereita; the most famous is El Doctor. North of it is the quicksilver-mine of San Onofre. There are also some lead-mines. The capital is Queretaro. [QUERETARO.] Cadereita, in the mining district, is a considerable place.

12. The state of S. Luis de Potosi comprehends by far the larger part of the southern portion of the great northern plain, and is traversed from west to east by the river Tamolin, an affluent of the Panuco. It is only rich in cattle. The mines are not numerous, but among them is the rich mine of Caterce. There are also some mines of copper. The capital, S. Luis de Potosi, is a large town, containing, with the adjoining villages, from 50,000 to 60,000 inhabitants. It has wide and well-planned streets, which are lighted by night. There are many large and substantial buildings, and numerous churches. The Palacio, or House of Congress for the state, a well-built edifice, occupies one side of the Plaza de las Armas; on the opposite side stands the cathedral: the two other sides are composed of shops and dwelling-houses. In the centre is a fountain. The town is well supplied with water by an aqueduct. The surrounding country is very productive in fruits, and the commerce is considerable.

13. The state of Zacatecas extends on both sides of the Sierra Madre, which traverses it towards its southern extremity in a north-western direction: the larger portion of

its territory lies on the great northern plain. The southern portion is productive in grain, and the northern arid plains contain abundance of cattle. Of the numerous mines, all of which are situated in the Sierra Madre, the most celebrated are those of Zacatecas and Sombrerete. The territory has nine lakes, from which carbonate of soda is collected in a crystallized state. Not far from the western boundary of this state, and south of the capital, an extensive tract is covered with immense ruins, called Los Edificios, which seem to mark one of the resting-places which the antient inhabitants of Mexico, the Aztecs, erected on their emigration towards the south. This state contains several populous towns. Sombrerete, Freznillo, Ierez, Pinos, and Nochistlán have each a population varying from 14,000 to 18,000: they are all situated near the mines. The capital, Zacatecas, with the adjacent village of Veta Grande, contains 28,000 inhabitants, and is built in a ravine between high hills. The streets are narrow and crooked, but the churches are very large buildings of stone: the most remarkable is La Búfa, which stands on a high eminence, and looks like a fortification. Aguas Calientes, situated towards the southern extremity of the state, in a richly cultivated country, has 35,000 inhabitants, and manufactures of cloth. The streets are narrow, and the houses substantially built. Its cathedral has the appearance of a Moorish mosque.

14. The state of Durango includes the Sierra Madre from 24° to 27° N. lat., and comprehends also an extensive tract of level country skirting the range on the east, and belonging to the great northern plain. The terraces by which the mountains descend on the east are rich in agricultural products, the plain itself in cattle, and the Sierra Madre in metals. The richest mines are near Guarisamey, San Dimas, and Gavilanes, situated in narrow valleys in the Sierra Madre, at an elevation of more than 9000 feet above the sea. There are also mines of lead and abundance of iron ore. Between the town of Durango and that of Nombre de Dios is a plain, covered with basalt, about thirty miles in length and fifteen in width. This plain contains an extinct crater, more than 100 yards in circumference, and thirty yards deep. This sterile tract is called Breña. The capital is Durango, or La Ciudad de Victoria, with 22,000 inhabitants, a well-built place, with wide streets and several fine buildings. Nombre de Dios has 7000 inhabitants. Papasquiario, in a valley of the Sierra Madre, near the rich mines, has a population of 6000. In the plain are S. Juan del Rio, with 10,000 inhabitants, and Villa de los Cinco Señores, on the Rio Nasas, along the banks of which cotton is grown.

15. The state of Occidente comprehends the provinces of Cinaloa and Sonora, or the whole tract extending between the Sierra Madre and the Gulf of California from 23° to 33° N. lat. It is rich in agricultural produce and fruits, though agriculture is in a backward state. It contains several mines of gold and silver; those of copper are still more important. At the most northern extremity, on the banks of the Rio Gila, and rather beyond the boundary of the state, are the Casas Grandes, ruins of numerous edifices which cover a large space. They are considered as one of the stations of the Aztecs in their emigration to the south. South of the Rio Mayo the population consists only of whites, but north of it are seven native tribes, Opata, Ceres, Pimas, Yaqui, Mayos, Yumas, and Turumaras, which subsist by agriculture. Along the northern boundary, on the Rio Gila, the Appaches and Axua Indians lead a wandering life. The most remarkable places from south to north are—El Rosario, with 6000 inhabitants, in the neighbourhood of some mines. It carries on some commerce by means of the harbour of Mazatlan, which is about sixty miles distant. This harbour is spacious, but not safe, as it has many dangerous shoals and islands at its entrance. Cosalá, a well-built town, contains 5000 inhabitants: in its neighbourhood are several rich gold-mines. Culiacan, with 11,000 inhabitants, is built on rising ground on the south bank of the river Culiacan, just above its confluence with the Rio Mayo. It carries on a considerable trade. El Fuerte, the capital of the state, was till lately a small village, and has only risen to be a thriving town since it has been made the seat of the state government. It is built on the southern bank of the Rio del Fuerte, and contains 5000 inhabitants. Los Álamos, between the Rio del Fuerte and Mayo, has about 6000 inhabitants, and considerable silver-mines in its neighbourhood. It contains many well-built houses, and carries on a considerable commerce. Santa Cruz, near the mouth of the Rio Mayo, the principal town

P. C., No. 932.

of the Mayo Indians, contains 10,000 inhabitants. Guaymas is the best port of Mexico on the Pacific, and capable of containing 200 vessels. It is secured from all winds by the elevated hills which surround the bay, and by Bird Island, which lies in the entrance. The town contains 3000 inhabitants, but suffers for want of water: the climate is hot, but healthy. Its trade with all the ports of the Mexican states along the shores of the Pacific is considerable. Pitic, on the Rio Pitic, has 8000 inhabitants, and is irregularly built; there are no streets, and the houses are scattered in every direction. It contains however some good houses, and carries on a considerable trade. Arispe, the most northern town of any importance, contains 3000 inhabitants, and is the principal seat of the military force which is situated in this part for the protection of the state against the Appaches. The lully country which lies to the west of this town, called Pimeria Alta, had the reputation of containing rich gold-mines, which however, on examination, have been found to be of little value. There are however valuable copper-mines.

16. The state of Chihuahua comprehends that portion of the northern plain which lies between the northern part of the Sierra Madre and the middle course of the Rio del Norte, together with the mountain-region of the Bolson de Mapimi, and a tract of country south of it. The soil is in general very dry, and unfit for agricultural purposes: cultivation is limited to the river bottoms and a narrow strip of country along the declivity of the Sierra Madre; but this state has many herds of cattle, horses, and sheep. The mines are rather numerous. The most important are in the Sierra Madre, at El Parral, Botapilas, and Jesus Maria: those of S. Eulalia are in a hill which stands isolated on the plain, about twelve miles from Chihuahua. Near the base of the Sierra Madre, and not far from the boundary-line between this state and Sonora, are ruins of great extent, called Casas Grandes, like those on the Rio Gila: these also are considered as one of the stations of the Aztecs in their emigrations. The population of the plain consists entirely of descendants of Europeans; but in the Bolson de Mapimi are the Comanches, and, along the northern frontier of the state, the Appaches and Chichimequos. The capital, Chihuahua, is a well-built town, with regular streets and many large houses. Its cathedral is an extensive building; and the town is well watered by means of an aqueduct, which is supplied by a river about eight miles above the town. Its population once amounted to 70,000, but at present it does not exceed 12,000. S. Bartolomeo, situated towards the boundary of Durango, contains a population of 28,000. It is badly built, and the streets are narrow, but it carries on a considerable commerce with the agricultural produce of the fertile district in which it is situated, consisting of wool, maize, cotton, and wild honey. Not far from it to the west is El Parral, which contained 50,000 inhabitants when the mines were productive, but now only 7000. Parras, near the lake of that name, is a small town in a district noted for its vineyards.

17. The state of Coahuila or Cohahuila extends over the north-eastern portion of the northern plain, over that which lies between the Bolson de Mapimi on the west, and the lower course of the Rio del Norte on the east, and which stretches southwards to the boundary of Zacatecas (25° N. lat.). To this extensive country is added the still more extensive tract to the north and east of the Rio del Norte, or the province of Texas. The most sterile portion of the northern plain is included in this state, and lies along the boundary of Zacatecas. Further north, between 27° and 29° N. lat., are several watercourses with fertile bottoms, and considerable tracts of cultivable ground. But cattle, and particularly mules and horses, constitute the commercial wealth of this country, and are exported in considerable numbers to the United States of North America. Texas is very fertile, but little cultivated. The north-western parts of the state are much exposed to the predatory incursions of the Appaches and Comanches, who inhabit the Bolson de Mapimi and the hills of San Saba. The capital of the state is Saltillo, situated near its eastern boundary and the edge of the table-land. It contains about 12,000 inhabitants, and is remarkable as the only place at which the steep declivity with which the table-lands of Mexico terminate towards the east can be passed by heavily laden carriages; farther south at least no such place is known to exist. It has several good streets, communicating at right angles with the Plaza, in the centre of which is a large reservoir, which supplies the

Vol. XV.—Y

town with water. It carries on considerable commerce. In this town a fair is held, which is much frequented by merchants from the adjacent states. Montelovez, farther north, has 3500 inhabitants. Santa Rosa, to the north-west of Montelovez, has 4000 inhabitants, and some mines in its neighbourhood. El Presidio del Rio Grande is situated where the Rio del Norte begins to be navigable for larger boats, and has 2500 inhabitants. Monclova, farther down, is a thriving place, with some trade.

Texas is almost entirely in its natural state. The Spaniards have only formed a few settlements in the districts adjacent to the Rio del Norte and the Rio Guadalupe, and their principal town is S. Antonio de Bexar, a small place. In the country farther east numerous emigrants from the United States of America and Europe have settled, but none of their settlements have attained any degree of importance, except S. Felipe de Austin, a small town.

This country has a good harbour in Galveston Bay, which is an extensive sheet of water, separated from the Gulf of Mexico by Galveston Island. The entrance to it, between the mainland and the eastern extremity of the island, has always twelve feet of water on the bar. The bay has generally about nine or ten feet of water, but towards its northern extremity, into which the navigable rivers Trinidad and S. Jacinto empty themselves, the bay is crossed by a bar, called Red Fish Bar, which at high tides has only five feet, and in northerly winds not more than three feet of water. The anchorage between Galveston Island and another smaller one, called Pelican Island, is good, in five fathoms of water, with a muddy bottom. The inhabitants of Texas who are not descendants of Spaniards have been for some years in a state of rebellion against the government of the United Mexican States.

18. The state of Nuevo Leon lies almost entirely to the east of the table-land, in the lower region which extends from it to the Gulf of Mexico, but it does not reach the shores of the sea, being separated from it by the intervening state of Tamaulipas. Though this country is not much elevated above the sea, and its climate resembles that of the Tierras Calientes, its surface is far from being so level as the country farther south. That part which lies south of the Rio del Tigre is indeed rather level, or undulating, but north of the river are mountains of great elevation, probably more than 10,000 feet above the sea, and in which some rich mines are found near Pesqueria and Salinas. The lower parts of the country are very fertile, but only cultivated in isolated places. Though the climate is hot, it is healthy. Monterey, the capital of the state, contains 15,000 inhabitants, and its commerce is considerable on account of the neighbouring rich mines. Linares has 4000 inhabitants, and the neighbourhood abounds in cattle.

19. The state of Tamaulipas extends along the Gulf of Mexico from the mouth of the river Panuco to that of the Rio del Norte, and still north of the latter to the Rio Nueces, but it does not reach farther inland than from 50 to 70 miles, except at its northern extremity, where it may be about 150 miles across. It is a low country, in which only a few hills occur, and it is unhealthy. Though very fertile, except along the sandy sea-shore, it is badly cultivated and thinly inhabited. Its coast-line, which is about 400 miles, is inaccessible on account of the long narrow islands which skirt it, but the navigation is not dangerous, as the soundings are very regular along the whole line. There are harbours only where the rivers join the sea, but their entrance is always crossed by bars, with only a few feet water on them. This circumstance is attributed to the current which, during the northern gales, sets with some force to the south. The commercial wealth of this state consists in its forests, in which fustic and logwood are cut to a great extent. The capital of the state is Pueblo Nuevo de Tamaulipas, situated at the southern extremity of the state, on the northern bank of the river Panuco, about six miles from its mouth. The harbour is good and safe, and the bar at its entrance has generally twelve feet of water, but the navigable channel is scarcely a cable's length across. The town, which was founded in 1825 or 1826, is rapidly increasing. Its commerce is considerable, as most of the European goods which are consumed on the northern plain are landed here. Sotto la Marina is a small harbour, not much frequented, near the mouth of a little river, the Rio de Santandero, on the banks of which is the small town of Santandero, formerly the capital. Matamoros, on the Rio de Norte, about 40 miles from its mouth, has about 3000 inhabitants; vessels

not drawing more than eight or nine feet water may ascend the river to this place.

20. The territory of New Mexico comprehends the whole vale of the Rio del Norte, extending from its source along its upper course to 35° N. lat., and also the desert del Muerto and a fertile tract of country south of it, extending from 32° 30' to 31° N. lat. From the northern district great numbers of sheep are sent to the southern states, and wool is exported. The southern district contains some tracts which are adapted to raising agricultural products and fruits. The mountainous country between these two districts contains copper-mines. The mountains to the east and west of it are inhabited by several tribes of Indians, as *Utaha*, *Nanahaws*, and *Keres*. Many of them are settled among the whites in the villages in the level country. Santa Fé, the capital, is built on a small stream which joins the Rio del Norte from the east, and at no great distance from the last-mentioned river. It contains about 4000 inhabitants, and has some commerce with the United States of America and the state of Chihuahua. North of it is the town of Taos, which, according to Humboldt's statement, has a population of about 9000 souls. Paso del Norte, in the district south of the desert del Muerto, has a population of more than 5000 souls, and is situated on the northern border of the northern plain. The surrounding country produces abundance of maize, wheat, and excellent fruits. Its wine and grapes are celebrated over the whole of the Mexican confederation. It owes its fertility to irrigation by means of canals which convey the abundant water of the Rio del Norte over a district of considerable extent.

21. Lower California, and—22. Upper California. [CALIFORNIA.]

Manufactures.—Before the Revolution (1810) there were many flourishing manufactures, the annual produce of which amounted to from eight to ten millions of Spanish dollars, or about two millions of English money. The most considerable were those of cotton and wool in the towns of Puebla, Cholula, Tlascala, Queretaro, Lagos, Guadalajara, and Tezcuco. The manufactures of soap, leather, and saddlery were also considerable. The manufacturers owed their prosperity to the high price at which, under a system of monopoly, European goods were sold in that country. After the harbours were thrown open to a free trade (in 1820) they began to decline. The manufactures of cotton are now almost completely destroyed. Those of wool are in a lingering state, but those of soap, leather, and saddlery seem to be on the increase.

Commerce.—The commercial intercourse between the coast and the table-lands is difficult on account of the steep ascent to the table-lands from the coast. On the east there are only two carriage-roads, as has been already observed, which lead to the table-land; and this is also the case on the western coast, where the communication between Acapulco and Mexico, and between San Blas and Guadalajara, is carried on by roads which are only passable to mules and horses. No such obstacle exists between the harbours of Mazatlan and Guaymas on the western coast, and the country farther back, but no road leads from them over the Sierra Madro, by which the goods landed at those places could be carried to Durango or the towns of the northern plain. Even in those parts where there is no obstacle to the use of carriages, the goods are commonly carried by mules, on account of the great number of these animals, and the low price at which they are bought.

The maritime commerce is considerable. In the beginning of the present century the exports, according to Humboldt, amounted to twenty-two millions of Spanish dollars, and the imports to fifteen millions of dollars. Between 1820 and 1830 however the exports considerably diminished, on account of the comparatively small produce of the mines, the precious metals constituting the principal article of exportation; and as they have not yet been restored to that flourishing condition in which they were before 1810, the amount of the exports probably still falls considerably short of the amount stated by Humboldt, for the other articles have not increased much. According to Humboldt's estimate the exports in 1803 consisted of the following articles, and their value in dollars:—

Gold and silver	17,000,000 dollars.
Cochineal	2,400,000
Sugar	1,300,000
Flour	300,000
Indigo	280,000

Salt meat . . .	100,000 dollars.
Hides	80,000
Sarsaparilla . . .	80,000
Vanilla	60,000
Jalap	60,000
Soap	50,000
Campeachy wood . .	40,000
Tabascan pepper . .	30,000

Spanish dollars 21,780,000

Ward, following the statement of official documents, found that in this estimate Humboldt had overrated the exports by 2,618,648 dollars; as no flour had been exported, and the exports of cochineal amounted only to 1,100,327 dollars, and those of sugar to 281,025 dollars. Though the facts which have come to our knowledge are isolated, and in many instances not well authenticated, we shall attempt to make a rough estimate of the exports for the years following 1830, preserving Humboldt's statement where we have no more recent data:—

Gold and silver . . .	14,000,000 dollars.
Cochineal	1,100,000
Sugar	300,000
Indigo	200,000
Salt meat	100,000
Hides	80,000
Sarsaparilla	80,000
Vanilla	100,000
Jalap	80,000
Soap	50,000
Campeachy wood . . .	100,000
Fustic	80,000
Tabascan pepper . . .	40,000
Coffee	20,000

15,230,000

This may be considered as an approximation to the amount of the exports from the harbours of the Gulf of Mexico, namely, from Sisal, Campeachy, Villa Hermosa, Alvarado, Vera Cruz, Tampico, Tamaulipas, Sotto Marina, and Matamoros. No estimate can be formed of the exports from the harbours of the Pacific, from Acapulco, San Blas, Mazatlan, and Guaymas, and from those of Upper California. We only know that a considerable quantity of sugar is sent to Guayaquil and Lima; that at the port of Guaymas much copper, which contains gold, is shipped for China, where, as it appears, an easy method is known of separating the metals; and that large quantities of tallow and salted hides, with some flour, are exported from S. Diego in Upper California. No kind of commercial intercourse seems to exist between Central America and the Mexican states, but a considerable number of mules and horses, and some wool, are exported to the United States of North America, chiefly from Cohahuila and New Mexico.

For want of a general and more recent estimate of the imports, we shall transcribe that of Humboldt, founded on facts which refer to the beginning of the present century. It may still be useful as showing the principal articles consumed in Mexico, and their proportion. Though the consumption of all these articles, with the exception perhaps of cocoa and wax, must have greatly increased, and especially that of cotton goods, yet it seems probable that their value in money is not greater than was paid for them at the time of Humboldt, as most of the articles were then sold for double and some even for four times the present prices. Cocoa does not appear at present to form a large article of import, great quantities of it being grown in the state of Tabasco.

Humboldt's estimate of the imports at the beginning of the present century is:—

Articles.	Value in dollars.
Ropas (linens, cottons, cloth, and silk) . .	9,200,000
Paper	1,000,000
Brandy	1,000,000
Cocoa	1,000,000
Quicksilver (for the mines)	650,000
Iron	600,000
Steel	200,000
Wine	700,000
Wax	300,000
	14,650,000

The commerce is mostly carried on in foreign vessels, as these states have a comparatively small number of merchant ships. The vessels of the United States of America almost exclusively visit the smaller ports, as Villa Hermosa, Alvarado, Sotto Marina, and Matamoros. In addition to the vicinity of the United States, their products differ from those of the Mexican states. All the products exported from Mexico find a ready market in the United States, and are easily paid for by the manufactured goods of those states and of Europe. The American vessels, being in general of a smaller size, can safely pass the bars of the rivers, which cannot be done by the larger British vessels, which are therefore chiefly confined to the harbours of Vera Cruz, Tampico, and Tamaulipas. Next in number to the American are the British vessels, and then those of France, from Bordeaux and Havre, and lastly those of the free German towns of Hamburg and Bremen. Swedish and Danish vessels rarely appear in these ports.

History and Constitution.—Though Columbus in his last voyage approached the peninsula of Yucatan, he did not come in sight of it. Thirteen years later (1517) the peninsula was discovered by Francisco Hernandez Cordova, who sailed along the coast from Cape Catoche to Campeachy Bay. The following year, Juan de Grijalva continued the discoveries along the same coast northward to the mouth of the Rio Panuco; he visited the islands of Sacrificios and S. Juan de Ulua, opposite the present town of Vera Cruz, and gave them the names which they still preserve. His account of the wealth of the country excited the desire of conquest. In 1519 Hernan Cortes landed at the place where Vera Cruz now stands, but the town which he founded and called Villarica was some miles farther to the north, near a small harbour named Chihauitzla. With his little army he soon ascended the table-land, numerous inhabitants of which he found united under a powerful sovereign, the king of the Aztecs, Montezuma, or more correctly Moctezuma. Within the limits of this empire there were some small republics, of which that of Tlascala united with Cortes. Cholula was also a republic, and the name of a third is preserved, that of Huajocingo; all three were situated within the territories of the present state of Puebla. The empire of the Aztecs did not extend over all the table-lands; the table-land of Michoacan constituted a separate and independent kingdom. After two years of continuous and laborious warfare, Cortes succeeded in overturning the empire of the Aztecs, and the smaller states were subjected to the Spaniards almost without a struggle. The position which the Spaniards held with respect to the natives of the country very much resembled that of the nations of German origin who overturned the Roman empire and settled in the countries of Western Europe. Like them, the Spaniards were obliged to establish a kind of feudal system, to protect themselves against the much more numerous native population. In Europe the victors and vanquished in the course of time united so as to form one nation, but such a change has not taken place in Mexico, and probably never will take place. The Spaniards and natives belong to two different races of men, differing in colour and in many other respects. The Spanish conquerors also had attained a higher degree of civilization, whilst in Europe the conquerors learned from the conquered the most useful arts of civilised life. Even now, more than three centuries since the conquest, the Spaniards and natives constitute two perfectly distinct classes.

As the number of the conquistadores, or companions of Cortes, was very small, in comparison with the native population, they were anxious to bring over more of their countrymen. A considerable number of Spaniards accordingly annually emigrated to Mexico, and there acquired great wealth, as officers of government, merchants, and adventurers in mining. As many of these Spaniards were possessed of extensive property in land within Mexico, their descendants the Creoles settled of course in that country, and their numbers were continually increasing. The Spanish government however seems not to have formed a correct idea of their condition among the natives, and to have thought that the government of that country could only be entrusted to persons who considered Spain as their native country; it therefore excluded all the Creoles, or descendants of Spaniards born in Mexico, from all offices of government, and even from commissions in the army. Such exclusion excited in them a considerable degree of ill-will against Spain and the Spaniards, which would probably have manifested

itself in resistance and rebellion, if they had not feared that the native population would take advantage of such a circumstance to effect their own destruction. They had still to fear another enemy, which had grown up imperceptibly among them. Few of the Spaniards had brought wives with them. From their intercourse with the native women sprung up a race called *metis*, or *mestizos*, which increased still faster than that of the Creoles, who however, being in possession of great wealth, were well aware that as long as a regular government subsisted they had nothing to fear either from the natives or the *mestizos*. This will account for the fact, otherwise difficult of explanation, that no signs of active dissatisfaction manifested themselves in Mexico during the first thirty years after the United States of North America had obtained their independence, though the Mexicans were well acquainted with the advantages which their neighbours had obtained. It is even possible that the political condition of Mexico would not have undergone any change for a long time, but for the events in Europe and in Spain in 1808. By the intrigues of Bonaparte the royal family were compelled to abdicate the throne of Spain, and he conferred the whole Spanish monarchy on his brother Joseph, then king of Naples. The Spaniards in Mexico and the Creoles were unanimous in declaring their resistance to the government established by the French. The viceroy could no longer receive orders from Spain, and it was necessary to organise a government which should act independently under a certain sanction, and with authority. But as to this point they disagreed. The Creoles wished to establish a national representation; the Spaniards opposed the measure, and prevented the establishment of a system of national representation for Mexico. The Creoles submitted: but the public mind had been agitated by the discussions which had taken place, and soon afterwards, in 1810, the natives and the *mestizos* rose against the government. They were headed by Don Miguel Hidalgo y Castilla, the cura or parish priest of Dolores, a small town in the state of Guanajuato. The Creoles sided with the Spanish government. Hidalgo, who had soon an immense force with him, took Guanajuato by storm, and occupied Valladolid, whence he advanced over the table-land of Toluca to that of Tenochtitlan. The Spanish governor sent a small corps against him, which was defeated by Hidalgo on the 30th of October at Las Cruces, a pass in the chain which separates the table-lands of Tenochtitlan and Toluca. But notwithstanding this victory, Hidalgo retreated, and eight days afterwards was in his turn defeated by Calleja at Aculco. Hidalgo retired to Valladolid and Guadalajara; and in the neighbourhood of the last-mentioned town he was again defeated, and soon afterwards taken prisoner and shot. In the meantime the whole country had risen in insurrection, and many leaders began to act separately. The most remarkable among them was Don Jose Maria Morelos, cura of Nucupetaro, who with great activity, talents, and success maintained the southern provinces in rebellion against the governor, and formed a *junta*, or central government, which in September, 1811, assembled in the town of Zatacuaro, in the state of Michoacan. But that town was soon afterwards taken by Calleja, and the *junta* were dispersed. Calleja however was soon obliged to march against Morelos, who had penetrated into the table-land of Tenochtitlan from the south. He was attacked by Calleja in the town of Cuantla y Amilpas, and after defending himself for nearly three months with great skill and gallantry, he abandoned that place and took Oaxaca. The *junta* was now increased by new members, and under the title of the National Assembly it declared the independence of Mexico, on the 13th of November, 1813. But after that event Morelos had less success in his daring enterprises; and in November, 1816, he was taken prisoner, conducted to Mexico, and shot. Many of his companions in arms maintained the conflict for some time, but they did not act in concert with one another, especially after one of them, Terán, had dissolved the congress, which had been transferred from Oaxaca to Tehuacán in the state of Puebla. The viceroy Venegas, supported by the gallantry and skill of Calleja, destroyed successively the armies of these chiefs, so that when Don Xavier Mina, the famous Spanish guerilla chief, landed in Mexico in 1817, the fortune of the insurgents was at so low an ebb, that he was unable to restore their cause, and he perished in the attempt. The country gradually became more tranquil, and in 1820 it was restored nearly to the same degree of order which it had enjoyed before 1808, to

which fortunate result the mildness of the new viceroy Apodaca materially contributed.

The events which occurred in Spain in the beginning of 1820 suddenly changed the aspect of affairs, and deprived Spain of the most valuable of her possessions in America, which it had regained at the cost of much blood and money. The Spaniards and the Creoles, who had formerly made common cause, were now divided into two parties, royalists and constitutionalists. Apodaca, who inclined to the former party, wished to overthrow the constitution in Mexico, and chose for his instrument Don Augustin de Iturbide, a young man, born in the province of Valladolid, of respectable but not wealthy parents. He had distinguished himself in the battle of Las Cruces, and always shown great attachment to the Spanish party. Iturbide had about 800 men under his command, when, on the 24th February, 1821, at the little town of Iguala, on the road from Mexico to Acapulco, he issued a proclamation, which since that time has been called the Plan of Iguala. Its object was to conciliate all parties. It was to establish the independence of Mexico, and still to preserve its union with Spain. To effect this, the crown of Mexico was to be offered to the king of Spain, and in case of his refusal, to one of his brothers, Don Carlos or Don Francisco de Paulo, provided they would consent to reside in the country. Though Iturbide had certainly exceeded the powers which he had received from Apodaca, the viceroy, seeing that this proposal met the wishes of most persons, took no step to crush Iturbide; and the Spaniards of the capital, alarmed at this delay, deposed him, and placed Don Francisco Novella at the head of affairs. But the disorders which always attend such violent changes gave Iturbide time to unite his troops with those of Guerrero, the only insurgent chief still existing in the country, and to bring over to his party all the western and northern provinces. Before the month of July, the whole country recognised his authority, with the exception of the capital, in which Novella had shut himself up with all the European troops. At this moment he received intelligence of the arrival at Vera Cruz of the new constitutional viceroy Don Juan O'Donoju. Iturbide hastened to the coast, obtained an interview with O'Donoju, and persuaded him to accept the Plan of Iguala as an armistice and final settlement, if it should be approved in Spain. This is called the treaty of Cordova, from the place where it was made. Iturbide thus got possession of the capital, where a *junta* and a regency were established, but in such a form that all power remained in the hands of Iturbide. By a decree of the Cortes, dated the 13th February, 1822, the treaty of Cordova was declared to be illegal, null, and void; and Iturbide, who had the power in his hands, and a great number of adherents, found no difficulty in ascending the throne. The army declared him emperor of Mexico on the 18th of May, 1822, and he took the title of Augustin I. He was acknowledged by the Mexican congress, which had been opened on the 24th of February; but a struggle for power soon arose between Iturbide and the congress, which the emperor terminated by dissolving the assembly in the same manner as Cromwell dissolved the Long Parliament, on the 30th October, 1822. On the same day he formed a new legislative assembly, composed of persons favourable to his wishes and intentions. But he had not skill enough to reconcile his companions in arms to these changes. Several generals declared against his proceedings, and prepared for resistance. Iturbide, terrified at the storm which was ready to burst on all sides, called together the old congress, abdicated in March, 1823, and went to Europe, whence however he returned to Mexico in 1824. He had been outlawed by the congress, and upon landing on the coast, he was shot at Padilla, in Tamaulipas. Thus Mexico obtained its independence and a constitution, without a civil war. But as this object had only been obtained by the energetic cooperation of the army, it was to be feared that the peace of the country would be interrupted by the discontents of the generals. This has in fact occurred several times; but happily such insurrections have been easily suppressed, with the exception of that got up by Santanna, who had distinguished himself in the struggle against Iturbide. Under pretext of the country being discontented with the administration, he collected an army in 1832, brought some other generals over to his side, and, after several conflicts, he succeeded in placing himself at the head of government. Being aware that he was less distinguished as a statesman than as a general, he undertook in person an expedition

against Texas, the population of which, consisting almost entirely of emigrants from the United States of America, had risen into open rebellion against the government. After some success, he was taken prisoner. This circumstance was favourable to the government, and since that time the peace of the country has not been materially disturbed.

The constitution of the republic was formed immediately after the fall of Iturbide, and the Fundamental Act was published on the 4th of October, 1824. The constitution is modelled on that of the United States of America, and most of the articles are transcripts of the corresponding articles in the constitution of that confederation. The legislative power is vested in a congress, which consists of two chambers, the house of representatives and the senate. The house of representatives is composed of members elected for a term of two years by the citizens of the states. Each state elects a representative for every eighty thousand inhabitants, and one more if there is a fraction exceeding forty thousand. Native Mexicans alone can be chosen, or such as have resided in the republic for more than eight years, who must also possess landed property to the amount of 8000 dollars, or some trade or profession which produces 1000 dollars annually. The senate is composed of two senators for each state, elected by a plurality of votes in the state legislatures. He who has the greatest number of votes retains his seat for four years; the other only for two years. The members of the senate must possess all the qualifications requisite for a deputy, and must also be thirty years of age; a deputy may be only twenty-five years of age. The congress meets every year on the 1st of January, and closes its ordinary sessions on the 15th of April; but an extraordinary congress may be called by the executive. The executive power is vested in a president and vice-president, both elected by the state legislatures for a term of four years. Native Mexicans only, who are thirty-five years of age and resident in the country, can be elected to these high offices. Though the great outlines of this constitution resemble, in all important points, those of the United States of America, the Mexican congress is vested with much greater power. It has not only a larger revenue, and the right of deciding on all matters respecting religion, but it has likewise the power of determining many points which in the United States of America belong to the several states. This difference arises from the different way in which the general congress was formed. In the United States of North America the state governments were fully organised before the formation of a general government, and in the Act of Confederation the states preserved all their original power which it was not thought expedient to confer on the general government. In Mexico however the general government had to establish the state governments, and could appropriate to itself as much power as it thought fit.

MEXICAN ARCHITECTURE. Although some light has of late years been thrown upon this subject, it is still involved in much obscurity; nor can we do more than advert to one or two points that deserve attention. The first of these is, that the older and more important monuments of Mexico are not, strictly speaking, Mexican, but the productions either of the Toltecs or of some still more ancient nation. Secondly, these remains are by some supposed to exhibit affinity, both in their general character and mode of construction, and the style of sculpture and the costume represented in them, to those of the Egyptians. Thirdly, hieroglyphic inscriptions on the walls of their edifices were employed by both people.

With regard to the aboriginal architecture of this part of America, it resembles that of Egypt, not only in the vast scale and massiveness of its monuments, but in the application of the pyramid, or of forms composed of it. Pyramids not inferior to those of Egypt, and some of even still

larger dimensions in their plan or base, exist in the Mexican territories; and examples of the second class occur in pyramid towers, consisting of a series of truncated pyramids placed one above another, each successive one being smaller than the one on which it immediately rests, so that it stands upon a platform or terrace. Of this kind was the pyramid tower or temple at Xochicalco, which, according to Nebel's restoration of it, consisted of five stories, and consequently had four terraces: its sides were ornamented with rude bas-reliefs, the figures of which were about four feet high and had a projection of three inches. The pyramid tower of Cholula resembles in no small degree the temple of Belus as described by Herodotus, inasmuch as it consists of eight stories, each forming a platform on which stands the one above it. The angle of inclination of these truncated pyramids is seldom less than 70 degrees, which differs little from that of the sides of the Egyptian temples.

Some of these edifices appear to have been not temples only, but to have contained sepulchral chambers and apartments for the priests; they had also descending galleries leading down into caverned recesses or halls, that were doubtless used either for religious mysteries or as places of concealment for treasure.

One of the most stupendous monuments of the style of architecture was the great temple at Palenque (built, according to the bold assumption of Lord Kingsborough, after the model of that of Solomon), which comprised within its extensive precincts various sanctuaries and sepulchres, courts and cloisters, subterraneous galleries, and cells for the habitation of the priests. The whole rests on a platform, composed of three graduated terraces, and forms a spacious quadrangle enclosed by porticoes. On each side of the exterior is an ascent or flight of stairs, and on the east a second flight leading down, after the first is ascended, into the cloistered court. Beneath the cloisters are what are conjectured to have been initiatory galleries; and in the centre of the quadrangle is what appears to be the ruins of an altar or 'high place.' The city of Palenque itself exhibits a variety of buildings, temples, palaces, baths, and private houses, all manifesting excellence of workmanship combined with considerable skill in design.

The remains of a palace at Mitla show that it must have been an edifice of great extent and grandeur; and the walls appear to have been sculptured or tooled externally, in imitation of mat or basket work, a species of decoration characteristic of Toltec taste, and often found in sepulchral chambers. This same building has also a portico with plain cylindrical columns differing from any found elsewhere.

In order to give an idea of the extraordinary vastness of some of these Mexican or Toltec constructions, we may adduce the instance furnished by the great teocalli, or pyramid, of Cholula, the side of whose base is 1440 feet, whereas that of the great pyramid of Jizeh is only 763 feet. The height however is, according to Humboldt, not more than 177 feet, and as the receding terraces are very wide, and the area of the upper platform or terrace small in comparison with the area of the base, the outline of the whole would not be that of a continuous pyramid, but merely such as might be inscribed within such figure.

At Teotihuacan, about eight leagues to the north-east of the city of Mexico, are an immense number of pyramids, several hundred small ones ranged in files or lines, and two larger ones consecrated to the sun and moon. Each of the latter is divided into four platforms, the slopes between which consisted of steps, and on the summit was a colossal stone statue covered with plates of gold, which were stripped off by Cortes's soldiers, and the statues themselves destroyed.

Besides monuments which are chiefly works of magnificence, others exist which attest the high degree of civilization attained by the Toltecs, such as Cyclopean roads and bridges. The former of these were constructed of huge blocks of stone, and frequently carried on a continued level, so as to be viaducts across valleys. There are also throughout Central America numerous excavations or rock-hewn halls and caverns, called by the natives 'granaries of the giants.' They resemble the Cyclopean fabric near Argos known by the name of the Treasury of Atreus, are generally dome-shaped, and the central apartment is lighted through an aperture in its vault. Other points of resemblance to Cyclopean masonry may be found in the doorways

to these subterranean galleries and apartments, which are similar to the gate of Mycenæ; and also in the peculiar triangular arch formed by courses of stones projecting over each other. Arches of this mode of construction are found in the cloisters of the building at Palenque. The remains of sculpture found in Mexico are numerous, and of great variety both of form and material. Captain Vetch has described (*London Geog. Journal*, vol. vii., p. 1) a collection of stone figures in his possession, which were recently procured from the banks of the river Panuco.

MEXICO, or, as it is now commonly written, Mejico, the capital of the United Mexican States, is situated in $19^{\circ} 25'$ N. lat. and $99^{\circ} 10'$ W. long., 7468 feet above the level of the sea. It stands nearly in the centre of an extensive plain, which, from being surrounded by high hills or mountains, is commonly called the Vale of Tenochtitlan, which was the name given to the town before the year 1530. This vale has an oblong form, extending from south to north fifty-two miles, and from east to west thirty-four miles. Its circuit, measured along the crest of the ranges which enclose it, is nearly 205 miles; and its area is 1710 square miles, or nearly equal in extent to the county of Lancaster; but about one-tenth of its surface, or 164 square miles, is occupied by four lakes. The largest of these lakes, that of Tezcuco, which covers a surface of 77 square miles, occupies the centre of the vale, and is only about three feet and a half lower than the great square of the town, which stands on its western shores, on swampy ground. Towards the southern extremity of the vale is the lake of Chalco, which contains a small island and the pleasant village of Xico, and is separated by a dike from the lake of Xochimilco. The surface of these two lakes is nearly four feet above the great square in the town, and they occupy nearly fifty square miles. Their water is fresh, while that of the other lakes is brackish or salt. North of the lake of Tezcuco is the lake of St. Christoval, which covers about twenty-seven square miles, and is nearly twelve feet higher than that of Tezcuco. It is divided into two parts by a dike, and its northern portion is called the lake of Xaltocan. The north-western corner of the vale is occupied by the lake of Zumpango, which is likewise divided into two portions by a dike: the eastern is called the lake of Coyotepec, and the western that of Zitlattepec. This lake is nearly thirty feet above the lake of Tezcuco, but occupies only ten square miles. During the rainy season the water, descending abundantly from the ranges which enclose the vale, is poured into these lakes, which have no outlet: the greatest quantity enters the lake of Zumpango, which is the most elevated. It frequently happened that in very wet seasons the water which accumulated in these lakes inundated the lower portion of the vale, and rose several feet in the streets of Mexico. To prevent such an occurrence the Spanish government caused a canal to be made through the mountains of Nochistongo, which lie north-west of the lake of Zumpango, by which the superabundant water from the lake is carried off. This stupendous work, known by the name of the Desague of Huehuetoca, is above twelve miles long, and for more than 1000 yards is cut through rocks from 60 to 75 feet high. It is justly considered one of the most astonishing hydraulic works in the world.

The mountains which enclose the vale are lowest on the north side, where they rise only a few hundred feet above the level grounds of the vale, but they are higher on the other sides, especially on the south and south-east. Near the south-eastern angle is Mount Istaccihuatl, which is 15,704 feet above the sea-level, and is always covered with snow. It is connected by a ridge with Mount Popocatepetl, which lies farther south, and attains the height of 17,884 feet. The surface of the vale itself is not a level plain, but is intersected by very irregularly shaped rocks, which are sometimes isolated and sometimes in groups singularly arranged. The most elevated are the Cuesta de Barientos, north of the town, which rises 288 feet above its base; and the Cerro de Chiconautla, which lies to the north-east, and rises 1055 feet above the lowest part of the vale. The districts between the western range and the lakes are richly studded with villages and towns, and contain extensive tracts of cultivated ground, where wheat and the other grains and vegetables of Europe are raised in abundance; but large tracts of country east of the lakes are sterile, the surface being covered with a saline efflorescence, and the cultivated spots and villages are distant from one another.

Mexico is one of the finest cities in the world. In the dry

season it is at some distance from the lake of Tezcuco, whose waters in the rainy season are sometimes driven by easterly winds to the eastern border of the town, which is protected against inundations by dikes. The streets are very wide, and at right angles to each other, so that by looking down any two at the point where they intersect each other, the spectator commands a view of nearly the whole town. They are all well paved, and have side-walks of flat stones. The private houses, though spacious, are rather low, seldom exceeding one story; but being constructed either of amygdaloid or porphyry, they have an air of solidity and even of magnificence. The moderate height of the public as well as private buildings is owing partly to the difficulty of laying a good foundation, as water is uniformly found at a very few feet from the surface, and partly to the frequency of earthquakes. In consequence of the water all the larger buildings are raised upon piles. The roofs of the houses are flat, and as they sometimes communicate with one another for a considerable distance, when seen from an elevation they look like immense terraces. The houses are all squares, enclosing open courts, which are surrounded by corridors. The entrance leads through a large gate into the court, and the stairs are opposite to the gate. The best apartments, which are generally painted, are towards the street, and all the windows are ornamented with balconies.

The squares are spacious and generally surrounded by buildings of hewn stone in a good style of architecture. The principal square is the Plaza Mayor, which, on two sides, is surrounded by the cathedral and the palace, and on the two other sides by shops and dwelling-houses, with the exception of the Casa del Estado, or the palace of Cortes. In the centre of the square was formerly a magnificent equestrian statue of Charles IV. of Spain, which has been removed since the Revolution. This square is the market for vegetables and fruits, those of the south of Europe being cultivated in the vale of Tenochtitlan itself, whilst the fruits of the tropics are brought from the plain of Cuantla Amilpas and from Istla. [MEXICAN STATES.] Manufactured goods are sold in the Portales, or covered colonnades, of which there are several on a large scale, and all well supplied with goods from Europe and China. Several principal shops open into the Portales, and innumerable petty venders display their wares, crowded on tables, in boxes and in baskets. The Parian, or bazaar, is a square building, divided into uniform compartments by two principal cross streets, and others subdividing it. The palace, in which the viceroy formerly was lodged, and which at present serves as the residence of the President of the United Mexican States, and also contains the senate-house and all the principal public offices, is a building of great extent, including a number of squares and inner courts with separate staircases and suites of apartments. One of these courts contains the botanic garden, which however has been much neglected of late. The College of Mines is a large edifice, built in a pure taste and magnificent style, but though finished hardly fifty years ago, it is falling to ruins, owing to some defect in the construction. It contains a rich collection of minerals, and in one of its rooms a professor gives lectures on chemistry and mineralogy. The Acordada, or great prison, is a substantial and large building, which will contain above 1200 prisoners. The hospital, now converted into artillery barracks, occupies a large site, and is well built. The university building is not distinguished by taste or magnificence; it contains a collection of Mexican antiquities, among which is the celebrated stone of sacrifice. The Academy of Arts, which is a fine building, contains a great collection of models, with casts of all the best statues of ancient and modern times, and a school for drawing.

The numerous churches and convents with their cupolas and steeples give the town a magnificent appearance. The cathedral stands on the ruins of the great *teocalli*, or temple, of the god Mixitli. One part is low and of bad Gothic architecture; but the other, built in the Italian style, is very handsome. The interior is lofty, magnificent, and imposing. In the outer wall of this church is fixed the *kellendu*, a circular stone, covered with hieroglyphic figures, by which the Aztecs or Mexicans used to designate the months of the year, and which is supposed to have formed a perpetual calendar. Among the numerous convents that of San Francisco is distinguished by its extent, architectural beauty, and wealth.

The Alameda, or public walk, at the western extremity of the town, resembles a park: it is laid out in lines, diverging

from different centres, and is planted with a great variety of trees. In the centre is a fountain, which is supplied with water from the great aqueduct leading from S. Fé to the city. The water is carried along in trenches, so as to water the plants and trees, and is then discharged into the lake of Tezcuco. As the ground on which the city stands is low, all the roads leading to it are raised six or eight feet above its level; they are broad, paved in the middle, and planted on both sides with double rows of trees. These roads, called *paseos*, afford delightful rides.

As the water of the lake of Tezcuco is even saltier than that of the Baltic, according to the experiments of Humboldt, and as the water which is found a few feet under the surface is also brackish, the city is supplied with drinkable water by two aqueducts, which bring it down from sources situated in the mountains west of the vale. The larger aqueduct, leading from S. Fé to the Alameda, and thence to the lake, is 11,155 yards long, and in one-third of its course is supported by arches of stone and brick plastered over. Its water, which is very pure, is distributed through the city. The other aqueduct, that of Chapoltepec, is 3608 yards long, and rests on 904 arches, which are nine and a half feet apart, and the columns four feet thick. The width is about six feet and a half. The stream of water is two feet and a quarter wide, and three feet deep. This water, which is less pure, is consumed in the suburbs contiguous to the city on the south.

The city is partly supplied with provisions and vegetables by small boats, which bring them over the lake of Tezcuco; but as the lake is very shallow in January and February, the supply is then generally stopped, and the city depends, especially for vegetables, on the supply by the canal of Iztapalapan, which leads from the lake of Xochimilco to the town. This canal is narrow, but always covered with small canoes loaded with fruits and vegetables: it passes through the chinampas, or floating gardens, which, in their present state, are long narrow strips of ground, redeemed from the surrounding swamp, and intersected by small canals. They are well cultivated, abound in fine vegetables, and their edges are planted with poplars. It is stated that they originally consisted of wooden rafts, covered with earth, and floated about in the lake when it was full of water, whence their name is derived. At present they are stationary, but it is said that there are still some floating gardens in the lake of Xochimilco.

The most remarkable object in the environs of Mexico is the palace of Chapoltepec, which is built on a rock, to the foot of which the water of the lake of Tezcuco extended at the time of the conquest by Cortes (1521). The palace, which was built by one of the viceroys of Mexico, is properly a fortress; but it is now in a very dilapidated state. The place is frequently visited by the natives and foreigners on account of the fine view it affords over the city and the greater part of the vale of Tenochtitlan. For the *teocallis* of Tezcuco, see MEXICAN STATES.

The population of Mexico amounts to between 140,000 and 150,000 souls, and consists mostly of Creoles, or descendants of Spaniards; the *Mestizos*, or descendants of Spaniards and Indians, not amounting to half that number. The lowest class of the people, called *Suragates*, *Guachinangos*, or *Lepores*, live in a state of abject poverty, which is owing to their indolent habits. They amount to about 30,000. The manufactures are not important, except those of plate and tobacco, which latter is carried on for the benefit of the government, as in all the Mexican states. Gold lace is also made. There are also a few manufactures of soap, cotton, and hats; but by far the greatest part of the manufactured goods for the consumption of the inhabitants are imported from Europe: silk stuffs, and especially stockings, also from China. The commerce of Mexico is limited to the importation of these foreign goods, and to the exportation of the produce of the mines. The city owes its present importance to the circumstance of being the residence of the federal government of the Mexican states, and of a great number of very wealthy individuals.

(Humboldt's *Essai Politique sur la Nouvelle Espagne*; Ward's *Mexico in 1827*; Poinset's *Notes on Mexico*; Lyon's *Journal of a Tour in the Republic of Mexico*; A *Sketch of the Customs and Society of Mexico*.)

MEXICO, GULF OF, is a mediterranean sea, which is united by numerous straits with the Atlantic, from which it is separated by a row of islands and widely extended banks. The long chain of the Antilles forms its eastern boundary

between 10° and 20° N. lat., and several small banks with the Great and Little Bahama Bank, extend along it from 20° to 26° N. lat. It is divided from the Pacific Ocean by the Mexican isthmus, which unites the two Americas. The length of the whole sea, from east-south-east to west-north-west, is not much short of 3000 miles. It is divided into two portions by the island of Cuba, which lies across the sea from east to west. Of these portions the southern, in modern times, has obtained the name of the Caribbean Sea, whilst that of Gulf of Mexico has been limited to the northern portion.

The Caribbean Sea, which extends from east to west nearly 2000 miles, or the distance from the British Islands across the Atlantic to Newfoundland, with an average breadth of less than 500 miles, is free from rocks and dangers to navigation between the Lesser Antilles and 80° W. long., except along the coast of Venezuela, where there are numerous steep rocks and islands which extend westward to 70°. West of 80°, and indeed from the innermost recess of the Gulf of Darien, the coast is lined by numerous reefs and low wooded islands, called keys, which in the Mosquito Gulf and the Bay of Honduras increase in number, and render navigation more intricate and dangerous. The Gulf of Mexico, or the northern portion of the mediterranean, is united to the Caribbean Sea by a strait about 120 miles wide, which is formed by Cape S. Antonio, the most western extremity of the island of Cuba, and Cape Catoche, the most northern point of the peninsula of Yucatan. The length of the Gulf, from Cape Sable in Florida to the eastern coast of Mexico, is more than 1000 miles, and its breadth towards the west more than 700 miles; but between Yucatan and Cuba, on the south, and the shores of Louisiana and Alabama, on the north, it does not exceed 550 miles. Shoals and small islands are rare within the body of the sea, and occur only along the northern coast of the island of Cuba and along the peninsula of Yucatan. Along the coast of Mexico the soundings are very regular, beginning at a distance of about 30 miles with 100 fathoms, and decreasing gradually as we approach the shores. At the eastern extremity, where the Gulf terminates in the old Bahama Channel and Florida Strait, the navigation is rendered very intricate by the Florida Reef, the Key Sal Bank, the Great Bahama Bank, and the numerous keys, shoals, and islets which surround the northern coast of Cuba.

The eastern trade-winds prevail in this sea during the summer from May to November, and on its eastern border along the islands all the year round. But along the coast of Venezuela and the shores of the Mexican isthmus the winds are subject to a regular change from November to April. In the Caribbean Sea calms and light winds succeed the trade-winds in November until the month of December, when the wind settles in the north-west, and varies only to the north up to the month of April. This wind blows in violent gusts and is attended with rain, but does not appear to extend beyond 12° 30' N. lat., to the north of which parallel the trade-wind always blows. Calms and light airs in April indicate the change of the wind, which soon settles in north-east and east. In the Gulf of Mexico the *Nortes*, or northern gales, are much dreaded by navigators. They begin in September or October, and become prevalent in November: they blow with the greatest force in March, and sometimes last to the month of April. These violent gales generally blow three or four days in succession, and last sometimes ten or twelve days. They are interrupted by moderate winds from the east, which commonly last three or four days. At the setting in of a 'norther' the larger vessels, which cannot enter the shallow harbours of this coast, are obliged to slip their anchors and leave the shore.

The currents in this sea are mostly independent of this change of winds. A strong current sets into the Caribbean Sea from the Atlantic. In the wide strait between the islands of Trinidad and Grenada it runs from one to one mile and a half per hour, but not so quick in those which lie farther north, yet the rate is about twenty miles per day as far as the island of Dominica; it then diminishes gradually to ten and even eight miles, which latter rate occurs near the Virgin Islands. The strongest current within the Caribbean Sea is met with along the coasts of Venezuela and New Granada: it runs westward the whole year round as far as the Gulf of Venezuela, but west of that bay only from May to November. When the easterly wind ceases in November the currents begin to run to the westward some

days before the north-west winds come on, and continue to flow in that direction to the month of April. But in the Gulf of Darien, the most southern corner of the Caribbean Sea, the order of the currents is inverted; they run westward from December to April, and eastward from May to November. These currents extend only about 24 or 30 miles from the shores, and in the body of the sea they are always westerly, and commonly weak, except in January and February, when they run with great force. This westerly current turns northward in the strait between Cape S. Antonio and Cape Catoche, and carries the water into the Gulf of Mexico, in the western portion of which sea a strong northerly current, running about ten miles a day, is perceptible, even during the northers. But along the shores of Mexico, and at a considerable distance from them, no current is met with, except when the northers blow, when a strong southerly current runs along the shores; and to this circumstance is ascribed the formation of the numerous long-extended islands which line these shores, as also the bars which lie before the embouchures of the rivers. Near the mouth of the Mississippi river the northern current turns eastward, and afterwards to the south-east. At the western extremity of Florida Reef the current divides: the greater portion of the water, turning eastward, forms the Gulf Stream; while the remainder, running westward along the reefs called the Colorados, winds about Cape S. Antonio and Cape Corrientes, and returns to the Caribbean Sea. The Gulf Stream carries the water back to the Atlantic. [ATLANTIC OCEAN.]

The Mexican Gulf may be entered by vessels through all the straits which divide the Lesser Antilles from one another; but navigators prefer the straits between Trinidad and Grenada, and between S. Vincent and S. Lucie, when they sail to the northern coast of South America. Vessels bound to Jamaica, Cuba, Mexico, and Louisiana, commonly choose the strait between Guadaloupe and Antigua; they rarely sail through the Mona Passage between Porto Rico and Haiti. But most of the vessels returning from these countries to Europe sail through the strait between Cuba and Florida, and follow the Gulf Stream, until they have entirely got out of the Florida Strait, when, turning eastward, they enter the Atlantic. Some vessels however, on leaving Jamaica and the countries farther south, direct their course to the Windward Passage between Haiti and Cuba, and thence to the Crooked Island Passage, by which they enter the Atlantic.

The Gulf of Mexico is remarkable for the high temperature of its waters. It raises the thermometer to 86°, while in the Atlantic, between the same parallels, the water does not exceed 77° or 78°. This high temperature is considered as the cause of the high temperature which the waters of the Gulf Stream preserve to a great distance from the Straits of Florida. In the centre of this sea, between the northern coast of Yucatan and the shores of Louisiana, great quantities of *fucus natans* are met with, extending in parallel lines from south-south-east to north-north-west. It was formerly supposed that the enormous quantity of this plant which is found in several parts of the Atlantic [ATLANTIC OCEAN] was derived from this sea, and that it had been brought down by the Gulf Stream; whence it obtained the name of Gulf-weed: but at present it is thought that this plant grows on the bottom of the sea, in those parts where it is met with, and that at certain seasons it is detached from its root.

(Humboldt's *Personal Narrative*, &c.; Rennell's *Investigation of the Currents*, &c.; Ulloa's *Voyage to South America*; and Lyon's *Journal of a Residence and Tour in the Republic of Mexico*.)

MEYER, JAMES, was born on January 7, 1491, at Vleter, a village near Bailleur in Flanders, from which place, agreeably to the custom of his time, he took the name of Baliolanus. After acquiring the knowledge of antient languages, he came to Paris, and went through a course of philosophy and theology. Subsequently returning to Flanders he embraced the clerical profession, and establishing himself at Ypres, opened a school, which in a short time acquired great celebrity. On being appointed incumbent to the living of the church of Saint Donatien, he removed his school to Bruges, and finally renounced it to accept the curacy of Blankenburg, where he died on the 5th of February, 1552. His remains were carried to Bruges and interred at St. Donatien. His principal works are: 'Flandricarum Rerum Decus,' containing the origin, antiquity,

nobility, and genealogy of the counts of Flanders; Bruges 1531, 4to.; and 'Chronicon Flandriæ, ab anno Christi 445 usque ad annum 1278,' Nürnberg, 1538, 4to.; 'Chronicles of Flanders, from the year 445 to the year 1278,' which was continued by his nephew to the year 1476, and published under the title of 'Annales Rerum Flandricarum,' Antwerp, 1561, fol.

MEYER, FELIX, was born at Winterthur in the canton of Zürich, in the year 1653. He studied first under an artist at Nürnberg, and afterwards under Ermels, a good landscape painter, whose manner he adopted. He went to Italy for improvement, but the climate not suiting his constitution, he returned to Switzerland. The beautiful and sublime scenery of that country supplied him with ample materials for numerous designs which deservedly gained him a high reputation and also fortune. To a lively and fertile imagination he added great facility of execution, of which he gave a remarkable proof at the abbey of St. Florian, in Upper Austria, where he happened to stop on his travels.

The abbot desiring to have two grand apartments painted in fresco, and having consulted another artist, who was very dilatory, asked Meyer for his advice as to the manner in which it should be executed. Meyer, after some minutes' consideration, took a long stick, to which he fastened a piece of charcoal, and immediately began to design, saying, 'Here I would have a tree;' which he sketched as quickly as possible; 'in the distance I would have a forest, thus; here a fall of water tumbling from great rocks, and so on;' designing as fast as he spoke, to the astonishment of the abbot, who immediately engaged him to undertake the work, which he entirely completed in the course of the summer. This adventure spread his reputation through all Germany, and from this time he was constantly employed by the princes and nobility.

In the latter part of his life he endeavoured to adopt a manner which should be at once more expeditious and more pleasing; but these latter performances are not equal to his earlier works, which give him a high place among the most eminent landscape painters. He was not skilful in drawing figures. His most esteemed works have figures by Roos or Rugendas. He died in 1713, at the age of sixty.

MEZEREUM. [DAPHNE.]

ME'ZERAI, FRANÇOIS EUDES DE, was the son of a surgeon named Eudes, and born in 1610, near Argentan, in the village of Rye. He studied in the university of Caen, and afterwards obtained the post of *Commis de Guerres*, which situation he subsequently gave up, and at Paris took the name of De Mezerai. Owing to great application he became dangerously ill, on which occasion the Cardinal Richelieu sent him 200 crowns, and the promise of his patronage. At Paris he produced his 'History of France,' which he afterwards enlarged by the introduction of verses, made by his friend Jean Baudoin, upon the principal persons of each reign; this latter edition had great success in 1646 and 1651; and a second and third volume appeared, both of which were equally fortunate. He also published several pamphlets directed against Cardinal Mazarin, under the name of Sandricour. An abridged edition of his 'History of France' appeared in 1668, and in 1662 his 'History of the Turks,' which is a translation from Chalcondylas. He succeeded Voiture in the Academy, and died in 1683.

Among other singularities, it is said of Mezerai, that he would shut himself up from the light of the sun at noon-day, and in the middle of summer, pursuing his avocations by candle-light; and, as if fearful that this eccentricity would not be generally known, he lighted his visitors to the door.

Mezerai, besides the harvest reaped from his works, which much exceeded his expectations, had several foreign pensions. His merits as an author are exceedingly doubtful; for, according to the writer in the *Biographie Universelle*, the extraordinary success of his 'History of France' was, in a great degree, due to the number of engravings it contained, consisting of portraits of kings and queens, which however were inserted without much regard to historic truth. His style is sometimes coarse, but generally clear, distinct, and forcible. Voltaire observes, that he lost his pensions for having told what he thought to be the truth. The same author observes, that he is more bold than accurate, and that his style is unequal.

ME'ZIE'RES, a town in France, capital of the department of Ardennes, situated on the Meuse, in 49° 46' N. lat.

and 4° 44' E. long.; 121 miles in a direct line north-east of Paris, or 144 miles by the road through Soissons, Reims, and R  thel.

This town is chiefly remarkable for the strength of its fortifications. In 1520 or 1521 it was successfully defended by the Chevalier Bayard against an army under the count of Nassau, sent by the emperor Charles V. to besiege it. It was taken by the Prussians in 1815, after sustaining a long bombardment.

The town is built on the slope of a hill, and is washed both on the north and south sides by the Meuse, which here makes a bend to the west, in the form of a horse-shoe. The houses are ill built, and the public buildings little remarkable. There are three churches, an hospital, an arsenal, and a theatre. Altogether the town suffers by the contrast between it and the neighbouring town of Charleville, which is to the north of it, separated only by the Meuse, and is larger and more regularly laid out, and better built than M  zi  res. [CHARLEVILLE.] The population of M  zi  res, in 1831, was 3737 for the town, or 3759 for the whole commune; in 1836, it was 4083 for the commune. The inhabitants manufacture leather, which is in high repute, and carpenters' and other mechanics' tools: there are some breweries. Trade is carried on in leather, serge, hosiery, and linen cloth. Building stone, lime, and sand are abundant round the town. There are three yearly fairs. There are some fiscal and administrative government offices here and at Charleville. There are a society of agriculture, sciences, and arts; a public library; and courses of instruction in geometry and mechanics applied to the arts.

The arrondissement of M  zi  res has an area of 363 square miles, and comprehends 99 communes. It is divided into seven cantons or districts, each under a justice of the peace. The population, in 1831, was 62,737; in 1836, it was 69,294.

MEZZOTINTO, in engraving, a peculiar mode of engraving designs of any description upon plates of copper or steel, with the view of obtaining impressions therefrom. In this style of engraving, which essentially differs from every other, the surface of the plate is first indented or hacked all over by the action of an instrument something like a chisel, with a toothed or serrated edge, called a *cradle*, or *mezzotinto grounder*. This tool being rocked to and fro in many directions, indents or bars the plate uniformly over its face, and produces what is called the mezzotinto grain or ground.

The barb, or nap, thus produced retains the printing-ink; and if in this state of preparation an impression were taken from the plate upon paper, it would be uniformly of a deep-black colour.

The directions, or *ways*, as they are technically called, given to the grounding-tool, are determined by a regulated plan, and for this purpose an ingenious sort of scale is used which enables the workman to pass over the plate in almost any number of directions without repeating any one of them. The mezzotinto ground being thus laid, it is at this period that the business of the artist properly commences. Having traced or drawn, with a pencil or other instrument, his outline upon the paper (unless indeed, as is sometimes the case, this should have been etched by the ordinary process, previous to the mezzotint ground having been laid), he proceeds to excise away the nap or ground, in conformity with the design, from all those parts which are not intended to be perfectly black in the impression. The instruments required for this purpose are scrapers and burnishers; with the former he scrapes away more and more of the ground in proportion to the brightness of the light, and the burnishers are used to produce perfect whiteness where it is required, as the high lights on the forehead or tip of the nose, or white linen in a portrait, &c. As the work proceeds it may be blackened with ink, applied with a printer's ball or otherwise, to ascertain the effect; after which the scraping may again be proceeded with, the artist taking care always to commence where the strongest lights are intended to appear.

The great facility with which mezzotintos are executed, as compared with line-engravings, will be obvious, seeing that it is much easier to scrape or burnish away parts of a dark ground corresponding with any design sketched upon it, than it is to form shades upon a white ground by an infinite number of strokes, hatches, or points, made with the *graver* or *etching-needle*. Herein consists the leading difference between this and all other modes of engraving;

P C., No. 932.

for while the process in each of these is invariably from *light* to *dark*, in mezzotinto it is from *dark* to *light*; and even the very deepest shades are produced, as we have seen, before the design is commenced. The characteristic or distinguishing excellence of mezzotinto engraving would seem to consist in the rich profundity of its shadows, the obscurity of which especially sympathises with fine effects of *chiar'oscuro*. It is therefore properly employed upon subjects where the quantity of dark predominates, as in the works of Rembrandt for example; and there can be little doubt that, had this process been known to that great master, he would have availed himself of it in multiplying his works. This opinion is sufficiently corroborated by the fact of his having sought and obtained the same effect, or nearly so, by leaving the *burr* on his etchings [ENGRAVING], which, retaining the printing ink, through a limited number of impressions at least, produced a result so nearly corresponding with mezzotinto, that many persons have been deceived by it, and led to attribute to Rembrandt van Rhyn the discovery of this more modern mode of procedure.

Having mentioned what we conceive to be the characteristic excellence of mezzotinto, viz. the richness and profundity of its shadows, it is but fair to add that its chief defect seems to be a corresponding poverty in the lights: and this objection will be felt to have much weight, when it is considered that it is to the lights in a picture that the eye is invariably attracted. On the lights therefore the line-engraver displays all that delicacy and beauty of line which agreeably irritates the eye and compensates for the absence of colour, by rendering the lights more interesting than the shadows. The lights in mezzotinto, on the contrary, where they occur in broad masses, have been ever felt by the judicious to be comparatively cold and poor. Of late however this objection has been much obviated by a judicious admixture of *etching* with the mezzotinto, which, by enriching the lights, has done much towards uniting the energies of both styles. Objection has also been taken to mezzotinto on account of the very limited number of good impressions which an engraving in this style would yield, in consequence of the very superficial nature of the ground. A work of this sort however was always susceptible of renovation by retouching, under more easy and satisfactory circumstances than one produced by any of the other modes; and latterly the introduction of steel plates, which are now commonly substituted for those of copper, has removed the objection entirely, a very large number of good impressions being thus ensured without the necessity of retouching. As copper-plates however are still occasionally used, it may be proper to state the respective numbers of good impressions that each may be expected to yield. On copper, the wear and tear of the plate much depend upon the number of *ways* it has been passed over in grounding, or the closeness of the teeth in the grounding-tool, the fineness of the grain depending upon these circumstances.

If the grain be not particularly fine, a copper-plate will furnish about one hundred and fifty good prints. When the plate begins to wear, the practice is to work it over again, partially, with the cradle; and afterwards to again have recourse to the scrapers, and in this way impressions of fifty at a time may be taken; so that by alternately retouching and printing by fifties, five hundred prints are frequently obtained from one copper-plate.

But from a *steel* plate eight or ten times that number may be obtained. The process is the same in the one case as in the other, but heavier *pressure* on the grounding-tool is requisite on a steel plate. A greater number of *ways* also is desirable, and these may be effected without rendering the subsequent engraving liable to more rapid deterioration, as would be the case upon copper. As many as ninety *ways* are frequently used on steel, while the number on a copper-plate varies from twenty-four to forty, which latter is rarely exceeded. It is scarcely necessary to say that steel plates, being especially liable to rust, require particular care in laying by.

From what has been said, it will be inferred that the manual operation of laying the mezzotinto ground is a very important, at the same time that it is a very laborious process. It is much to be wished that some means of effecting it by machinery could be devised; and we see no reason to doubt that this could be accomplished with equal and perhaps superior results to those obtained by the present mode of procedure.

The discovery of the art of engraving in mezzotinto has been a subject of some controversy, and, almost up to the time of our writing, of much uncertainty; but circumstances have recently transpired which we are among the first publicly to announce, and which enable us to set the matter completely at rest, and to give the honour of the invention to its real author, the rarity of whose productions has hitherto favoured the pretensions of one who has shown himself but too willing to strut in borrowed plumes. The account commonly given of its discovery is, that Prince Rupert, observed one morning a soldier engaged in cleaning from his musket the rust which the night-dew had occasioned, and perceived upon it, as he thought, some resemblance to a figure; it occurred to him whether or not, by corroding or grounding a plate all over in a manner resembling the rust, he might not afterwards scrape away a design upon it, from which impressions might be obtained. In short, it is said that he tried and succeeded, and thus became the inventor of mezzotinto engraving. If mezzotinto really had its origin in such circumstances as these, which is far from being improbable, they must have occurred to another rather than to Prince Rupert, since he was certainly not the discoverer of this art, as we shall presently show.

The merit of the discovery has been claimed by some authors (and even of late by a writer now living) for Sir Christopher Wren, on the ground of a communication which he made to the Royal Society in 1662, the Journals of which Society for October in that year record that 'Doctor Wren presented some cuts, done by himself in a new way, whereby he could almost as soon do a subject upon a plate of brass or copper, as another could draw it with a crayon upon paper.'

Previous to setting up the claims for Sir Christopher Wren, one would have thought that an ordinary spirit of research would have led his biographer to consult the engraved works in mezzotinto of Prince Rupert, which are not numerous, and, we believe, do not exceed twelve in number. He would then have found that his principal work (which is the Decollation of St. John the Baptist, after a design by Spagnoletto) bears date 1658, which is four years earlier than Sir Christopher Wren's communication to the Royal Society. In 1662, the year in which Sir Christopher Wren made this communication, the Royal Society was founded; and in the same year the celebrated John Evelyn (who was nominated by the king one of the original members, and of the council) published his 'Sculptura,' in which the first announcement of the new art, in England at least, appears; and he distinctly claims the honour of the invention for Prince Rupert, in a chapter 'on the new method of engraving, or mezzotinto, invented and communicated by his highness Prince Rupert, count palatine of Rhine,' &c. He embellishes the chapter with a specimen from the prince's own hand, and concludes it by alluding to an account of the process, which he is 'preparing to be reserved in the archives of the Royal Society;' and, as we have already seen, Prince Rupert's most capital performance actually bears date four years earlier: so that there is no pretence for giving the invention to Sir Christopher Wren on the ground of anything which he produced, or any communication which he may have made in 1662.

But while we have thus shown that the pretensions of Prince Rupert completely supersede those of Sir Christopher Wren, it remains for us to prove that those of Prince Rupert himself are invalid, and that he was guilty of an act of meanness in imposing upon John Evelyn, and this to the extent of allowing a man of his high character to impose in turn, however unconsciously, upon the world, by claiming for Prince Rupert the honour of an invention to which the prince well knew all the while that he had no title.

The real inventor of this art was Louis von Siegen, a lieutenant-colonel in the service of the Landgrave of Hesse Cassel, from whom Prince Rupert learned the secret when in Holland, and brought it with him to England, when he came over a second time in the suite of Charles II. Some curious and very rare prints recently purchased on the Continent, and now deposited in the British Museum, will enable us to place the claims of Von Siegen beyond doubt.

It is true that the Baron Heneiken long since ascribed the invention to its true author; and in his 'Idée Générale d'une Collection Complète d'Estampes,' printed at Leipzig in 1771, he distinctly asserts that Prince Rupert learnt the art from Von Siegen, whose first specimen made public was a portrait of the Princess Amelia-Elizabeth of

Hesse. But although Baron Heneiken is an author of acknowledged credit, we must have continued to speak with caution on the subject, because we believe Baron Heneiken does not give the date of this engraving, nor profess to have seen an impression of it. In the collection however lately purchased for the British Museum there is an impression of this identical portrait, and it bears date 1643, which is *fifteen years anterior* to the earliest of Prince Rupert's dates. In the same collection there is another curious work by Von Siegen, a portrait of the queen of Bohemia, the date of which is also 1643, which we think places the question beyond all dispute. But there is among them one specimen which we regard as more curious than any of the others; for although without a date, it bears, we think, the most conclusive internal evidence of having been produced in the very infancy of the art, since it exhibits a total misconception or misapplication of its peculiar local powers, which, as we have said, are especially calculated for large masses of shadow of an indefinite character, such as a plain background to a portrait. Now the work to which we allude, which is a portrait of the princess of Orange the eldest daughter of Charles I., is a mixture of line-engraving and mezzotinto, and in it the background (which, if the mixed style be used, would be best effected by the mezzotint ground) is performed wholly in cross-hatches by the old process; while the flesh and even the hair, in which line-engraving might have been applied with advantage, are produced wholly by the new process of mezzotinto. There are works by Theodore Caspar Fürstenburg, who also probably learnt the art from Von Siegen, which bear date 1656, being earlier than anything by Prince Rupert; but the works both of Fürstenburg and Prince Rupert are engraved entirely by the newly discovered process of mezzotinto, and evince a more matured knowledge of its powers than those of its inventor Von Siegen.

We will only further add the remarkable fact that Von Siegen frequently attached the word 'inventor' to his works, of which we subjoin an instance in the inscription to a 'Holy Family,' engraved by him after Carracci, and one of his latest performances: 'Eminentissimo Principi Domino D. Julio Mazzarini, S.R.E., Cardinali, &c., novi hujus Sculpturæ modi *primus inventor* Ludovicus à Siegen humilissime offert, dicat et consecrat. A^o 1657.'

It is not improbable, notwithstanding what we have said, that Prince Rupert, by himself or with the assistance of Wallerant Vaillant, an artist whom he retained in his suite, may have improved the mechanical mode of laying the mezzotinto ground; and it should also be stated that there is by Sir Christopher Wren a head of a blackamoor which is thought to have been done by a process differing from that of Prince Rupert. But these observations relate not to the principle of the art, but merely to the tool with which the *ground* is produced. The more perfect instrument at present used (i.e. the *cradle*) is said by Bartsch to have been invented by Blooteling, a very skilful engraver in mezzotinto, who produced many of his works about A.D. 1672.

It is in our own country that mezzotinto engraving has been carried to the greatest perfection. The principal artists previous to the present century were James M^r Ardel, Richard Houston, Valentine Green, Dixon, the two Watsons (Thomas and James), and one who contributed more perhaps to the improvement of this art than any one else, Richard Earlom, whose works, embracing almost every class of subject (history, portrait, still life, &c.), are well known, and are in almost every collection of importance in the country.

MHEYSIR. [HINDUSTAN, vol. xii., p. 211.]

MIAMI. [OHIO.]

MIASMA is a Greek word (*μῑasma*) signifying pollution or corruption generally; and is employed to designate a certain volatile deleterious principle, arising either from the bodies of the sick, from animal or vegetable substances, or from the earth, and capable of exerting a morbid influence on those exposed to its action. To the terrestrial emanations the Italians have given the name of Malaria (from *mala* and *aria*, bad air), and this word has been generally adopted into other languages: to those emanations arising from the bodies of the sick, the term contagion is more properly applied. In common parlance then, miasma is seldom employed to designate the contagious effluvium of disease; but, with the adjunct marsh, is restricted to the sense in which malaria is used; hence we speak of marsh miasma and malaria as one and the same thing. Though marshes,

whether salt or fresh, are prolific sources of malaria, they are by no means the only sources; the mud which is left by the drying of extensive ponds and lakes, the half-wet ditches of fortifications, and neglected sewers and drains, are capable of furnishing this poison. The decomposition of vegetable matter, in other circumstances than in connection with soil, is likewise capable of producing it; this has been exemplified in the sickness of ships from the leakage of sugar into a damp hold. The fever which made such fearful ravages among the crew of the *Priamus* frigate, arose from the action of bilge-water on chips and shavings left in the hold. Having enumerated some of the sources of miasma, the question naturally suggests itself,—what are the conditions essential to its development? The mere name of marsh miasma suggests the idea of stagnant water, and if the preceding enumeration of circumstances under which the production of malaria takes place be examined, it will be found that vegetable matter and moisture are present in all the examples, and that animal matter is so occasionally. But how great soever may be the share which moisture has in its production, it is certain that only a very small proportion is necessary: a marsh, the whole surface of which is thoroughly wet, is comparatively innocuous; but if partially or entirely dried by the summer's heat, it becomes extremely pestilential in autumn; indeed malaria, in its most intense degree, has been met with in low lands which had become as dry as a brick ground, with the vegetation utterly burnt up, and hence a high temperature seems to be another agent necessary, or at least favourable to its development. According to Dr. Ferguson, the only condition indispensable to the production of marsh miasma on all surfaces capable of absorption, is the paucity of water where it had previously recently abounded, a rule to which he assures us there is no exception in climates of high temperature. Of the chemical and physical properties of malaria nothing is known, even the very obvious question whether it is always the same kind of poison, or whether a multiplicity of these may not exist, is one which the present state of our knowledge does not enable us to answer. The occasional existence of putrefaction in conjunction with malaria is an accidental concomitant, but by no means essential to its activity as a poison. With regard to the effects of malaria, these manifest themselves in a longer or shorter period after exposure to its influence, and consist chiefly in the production of intermittent, remittent, and yellow fevers, dysentery, and typhus. The long-continued application of the same poison in a diluted form gives rise to various disorders of minor import, gradually undermines the constitution, and produces premature old age; even the inferior animals and vegetables partake of the general depravation which characterises malarious districts. The most efficient means of preventing the generation of the malarious poison, and, by consequence, the diseases to which it gives rise, are, the draining of swampy lands, and preventing the accumulation of putrid or putrescible vegetable or animal matter.

MAZZI, GIOVANNI, an Italian architect of the eighteenth century, born at Bergamo, in 1699, was originally brought up to his father's trade of carpenter. He was almost entirely self-educated in the profession which he afterwards followed; for it was not till he was forty that he availed himself of the instructions of Preti, who was his junior by two years. He had however previously built a small theatre in his native town, and the church of *La Trinità* in the Borgo of Angarano. One of his later and best works is the church of *S. Giambattista* at Bassano, in which he successfully overcame the numerous obstacles arising out of the site and the conditions he was obliged to comply with. He also built the collegiate church at Schio, that at Valdagno, another at San Vito, and a fourth at Simonzo, besides that at the convent of Monte Gargano, in Puglia. The Spineda palace, at Venegazza, in the Trevegiano, excited much admiration for the elegance of its design, which has since been greatly impaired by the demolition of the chapel and corresponding wing, and the arcades uniting them to the central edifice. The beautiful theatre at Treviso is another of his works; for although the original design proceeded from Bibbiena, he greatly improved it; and the façade, the vestibule, and many of the internal arrangements are entirely his own. Mazzi died about 1780, and, notwithstanding his age, continued vigorous and active almost to the last.

MICA. [LEPIDOLITE; MARGARITE; ODERIT.]

MICA SCHIST, one of the earliest groups of strati-

fied rocks known to geologists, and very extensively distributed throughout the mountain regions of the globe, often in contact with granite, but more frequently superposed on gneiss. It is frequently interstratified with gneiss, primary limestone, quartz rock, chloritic schist, and clay slate, and is deficient in organic remains. There are however certain more recent assemblages of strata more or less allied to mica schist in composition, of very limited area, adjacent to granitic elevations, in Dauphiné, &c., which do contain organic remains of the secondary periods.

To the British geologist the southern Highlands of Scotland and the mountains of Donegal offer abundant and striking examples of mica schist, with its associated limestones, quartz rocks, &c., while round the granites of the Isle of Man, Cumbria, Devon, and Cornwall, hardly a trace of gneiss or mica schist has been observed.

Composition. Mica schist, in its most typical state, differs from gneiss by the absence of felspar, but among the early stratified rocks the gradations and permutations of ingredients are so frequent as to confound all merely mineral distinctions, from hand specimens. The mica is usually spread through the rocks of this series in continuous surfaces overspreading the quartz portions, whereas in gneiss this seldom happens. In respect of the magnitude, relative abundance, and crystalline aspect of the ingredients of mica schist, there is every possible variation, so that some specimens approach obscurely to granite, others to well defined gneiss, and others to clay slate.

Dr. M'Culloch, a good authority on subjects of this nature, proposed the following synopsis of micaceous schist.

Division I. Consisting of mica and quartz.

Subdiv. 1. Simply laminar or foliated.

- a. Composed principally of continuously laminar mica.
- b. Composed principally of continuously laminar quartz.
- c. The mica discontinuous, the quartz granular.
- d. The mica greenish, approaching to chloritic schist.
- e. Mica grey, approaching to talcose schist.
- f. Approaching to clay slate.

The rocks of this subdivision are frequently and remarkably contorted.

Subdiv. 2. Granularly laminar.

- a. Granular quartz, with scales of laminar mica.
- b. Laminar quartz, with mica in scattered spots.
- c. Laminar quartz, with distinct scales of mica.
- d. Laminar quartz, with mica in parallel lines, so as to appear fibrous on splitting. (Avanturine seems to be of this nature.)
- e. The mica bent and contorted round the grains of quartz.

Division II. Compounded of three or more ingredients.

- a. With hornblende.
- b. With felspar (passing to gneiss).
- c. With chlorite or talc (passing to talcose or chloritic schist).
- d. With more than one of these ingredients.
- e. With carbonate of lime.

Division III. Conglomerated, or containing superadded fragments of granite, gneiss, limestone, &c. (In Isla, Garveloch, Rannoch, &c.)

Besides the minerals above noticed, many others occur in mica schist, so as universally to modify its aspect. This is particularly the case with garnet, which is often perfectly crystallized amidst the mass of fragmentary mica and quartz, and is so frequently met with in mica schist, that it seems to mark a particular condition through which the rock has passed since its first deposition.

The circumstance which perhaps more than any other deserves attention in studying these rocks, is the character of their stratification. Where limestones or clay-slates alternate with the mica schist, its strata are easily traced; but in cases where entire mountains are formed of laminated mica and quartz, the contortions to which the whole is subject render it very difficult to determine the prevalent dip of the beds.

It is difficult to avoid the belief that the smaller contortions of gneiss and mica schist are due to causes quite distinct from violent movement; they are characteristic of a peculiar mode of deposition, or marks of a subsequent modifying process; whether the great contortions may be thus explained, or require the supposition of great disturbances of position, is not easy to determine. [Geology; Rocks.]

MICAH (מִיכָא), one of the twelve minor Hebrew pro-

phets, is called in the title to his prophecy the Morasthite, and thus he is distinguished from Micaiah, the son of Imlah, who prophesied the death of Ahab, about B.C. 897. (1 Kings, xxii. 8-28.) This appellation was probably derived from his birthplace, Moresheth-Gath (*Micah*, i. 14), or Mareshah, a city of the tribe of Judah. (*Micah*, i. 15; *Josh.*, xi. 44; 2 *Chron.*, xi. 8; xiv. 9-10.)

From the title to the book of Micah we learn that he prophesied in the days of Jotham, Ahaz, and Hezekiah, kings of Judah, or from 759 to 699 B.C. The kings of Israel during this period were Pekah and Hoshea. Thus Micah was contemporary with the latter part of Hosea's prophetic ministry, and with Isaiah. This date is confirmed by a reference made to the prophet by Jeremiah (xxvi. 18, 19), who quotes his prophecy respecting the destruction of Jerusalem (*Micah*, iii. 12), and says that it was uttered by Micah in the days of Hezekiah. He must have delivered his prophecy before the sixth year of Hezekiah (B.C. 722), in which the kingdom of Israel was destroyed, for he speaks of that calamity as a future event. (*Micah*, i. 6, &c.)

Hartmann contends that Micah prophesied after the fourteenth year of Hezekiah, and that the book which bears his name is a collection of different prophecies made during the Babylonish captivity, some of which are Micah's, and others not. (*Micah, neu übersetzt und erläutert*, Lemgo, 1800.) This hypothesis, which is totally at variance with all the testimony we have on the subject, and is not sustained by internal evidence, on which it professes to be founded, has been amply refuted by Jahn (*Einleitung*, vol. ii., p. 430) and Rosenmüller (*Scholia in Vet. Test., Proem. in Mic.*).

Micah prophesied both to Israel and Judah (i. 1). He begins by predicting the overthrow of both nations, upbraids them with their cruelty, injustice, and impiety, and concludes this part of the book with the striking prophecy of the destruction of Jerusalem, which Jeremiah quotes, and which some suppose to refer to the taking of the city and the razing of the temple by the Romans. (chaps. i., ii., iii.) He next prophesies the restoration of the people to Jerusalem (iv. 1-8), after they shall have been carried captive to Babylon (iv. 9, 10), and the destruction of their enemies (iv. 11, 13). He foretells the birth of the Messiah at Bethlehem, after great calamities (v. 1-3), his ministry, and final triumph (v. 4-15). In chap. vi. he again reproves the people for their ingratitude, irreligion, and injustice. In chap. vii. Jerusalem is represented as complaining of the corruption and faithlessness of her sons, but patiently waiting for deliverance from God (ver. 1-10). The prophet consoles her with the promise of her restoration (ver. 11-13), and concludes his book with a sublime prayer to God for the fulfilment of that promise (ver. 14-20).

'The style of Micah,' says Bishop Lowth, 'is for the most part close, forcible, pointed, and concise, sometimes approaching the obscurity of Hosea, in many parts animated and sublime, and in general truly poetical.' (*Prælect.*, xxi.)

The canonical authority of this book is undisputed. One of the most remarkable predictions in it (v. 2) is quoted in the New Testament as being understood by the Jewish priests and scribes to refer to the birth of the Messiah. (*Matt.*, ii. 6.)

(Rosenmüller's *Scholia in Vet. Test.*; the Introductions of Eichhorn, Bertholdt, Jahn, De Wette, and Horne; *The Minor Prophets*, by Newcome and Horsley; *Micah, übersetzt und erläutert*, von K. W. Justi, Leipzig, 1820.)

MICHAEL'S MOUNT. [CORNWALL.]

MICHAEL, SAINT. [AZORES.]

MICHAËLIS, JOHN DAVID, was born at Halle on the 27th of February, 1717. His father, Christian Benedict Michaëlis, was professor of theology in the university of Halle, and a distinguished Hebrew scholar. After receiving instruction for some time from private tutors, Michaëlis spent four years in the orphan school at Halle, where his attention was particularly directed to languages and philosophy. In 1733 he began to attend the lectures at the university, and it was here that he obtained from the chancellor Ludwig's lectures on German history the foundation of that knowledge of general law and of the constitution of society which was afterwards displayed in his '*Mosaïches Recht*.' After taking his degree in 1740, he visited England, where he made the acquaintance of several eminent scholars both in London, and in Oxford. During part of

his residence in England he preached at the German chapel in St. James's Palace. On his return to Germany he devoted himself to the study of history, Oriental languages, and biblical criticism. At the death of the chancellor Ludwig, Michaëlis was commissioned to arrange and catalogue his immense library. The catalogue was published in 1745, and is considered a model for such works.

In 1745 he went to the university of Göttingen at the invitation of Münchhausen; and there he spent the rest of his life, although he was invited by Frederick the Great, in 1763, to return to Prussia. To the university of Göttingen Michaëlis rendered the most important services, as professor of theology and Oriental literature from 1745 to 1791; as secretary and director of the Royal Society of Sciences, from 1751 to 1770, when he left it on account of some differences with the members; as editor of the journal entitled '*Gelehrte Anzeigen*' from 1753 to 1770, and as librarian and director of the philological seminary, which would have been abandoned after the death of Gesner in 1761, if Michaëlis had not consented to direct it gratuitously.

In order to throw new light upon biblical science, Michaëlis planned the expedition to Arabia and India which was conducted by Carsten Niebuhr. The first project of this enterprise was submitted in the year 1756 to the Baron von Bernstorff, then minister of Frederick V., king of Denmark. The choice of the travellers was entrusted chiefly to Michaëlis, who drew up a series of questions for their guidance.

In 1775 Michaëlis was made a knight of the Polar Star by the king of Sweden; in 1786 he was appointed an Aulic counsellor of Hanover, and in 1789 he was elected a Fellow of the Royal Society of London. He died on the 22nd of August, 1791. He was twice married; by his first wife he had only one son, Christian Frederic; by his second he had nine children, of whom one son and three daughters survived him.

The mind of Michaëlis was strongly characterized by independence. He always acted in the spirit of his motto '*libera veritas*.' But his love of independence often led him to undervalue the labours of other learned men, and to do injustice to some of his most distinguished contemporaries. He often appeared to delight in discovering difficulties solely that he might have the pleasure of removing them. In the examination of the Old Testament he treated the Masoretic traditions with a contempt hardly less extravagant than the reverence entertained for them by the school of Buxtorf; and in every department of criticism he was apt to hazard ingenious conjectures in opposition to all real evidence. Though a good Hebrew scholar, he never possessed an accurate knowledge of the classical languages, and his acquaintance with Arabic was superficial. Notwithstanding these defects, his contributions to biblical and Oriental learning are invaluable, especially when he treats of subjects capable of illustration from history and philosophy. His religious opinions were never firmly fixed, but he invariably expressed the greatest reverence for the Scriptures.

The works of Michaëlis are very numerous; the following are some of the most important. In Oriental literature, grammars of Hebrew, Chaldee, Syriac, and Arabic, and treatises on various subjects connected with these languages; '*Oriental and Exegetical Library*,' 24 vols., New do. 8 vols.; '*Supplementa in Lexica Hebraica*,' 6 vols. In philosophy, an essay '*On the Influence of Opinions on Language and of Language on Opinions*,' which obtained a prize from the Prussian Academy of Sciences in 1759; a treatise on moral philosophy, and other works. In history, geography, and chronology, '*Spicilegium Geographiæ Hebræorum extera post Bochartum*,' other treatises on geography and chronology; several separate dissertations on the laws and antiquities of the Jews, the substance of most of which is embodied in his '*Mosaïches Recht*,' in 6 vols., 1770-75; a second edition of the first 5 vols. of this work was published in the years 1775-80. This work, which is considered the masterpiece of Michaëlis, was translated into English by Dr. Alexander Smith, in 4 vols. 8vo., 1814, under the title of '*Commentaries on the Laws of Moses*.' 'The great object of Michaëlis in this work is to investigate and illustrate the philosophy of the Mosaic laws, to show their wonderful adaptation in every respect to the very peculiar circumstances in which the people to whom they were given had been placed by providence; and, while he

takes every opportunity of establishing the claims of Moses to the character of an ambassador from heaven, to inculcate upon human legislators the important lesson of studying those particulars respecting the nature and political situation, the ideas and prejudices, the manners and customs of their countrymen, by attention to which alone they can ever hope to make them virtuous, prosperous, and happy.' (Dr. Smith's *Preface*, p. xvii.) In biblical criticism Michaëlis's *Introduction to the New Testament* is well known in England by the translation of the late Bishop Marsh; he also published part of an 'Introduction to the Old Testament,' a 'Translation of the Bible, with Notes, for the Unlearned,' and several other critical works. (Professor Hassencamp's *Collection of Memoirs relating to the Life and Writings of Michaëlis*; and *Biog. Univ.*, vol. 28.)

MICHAELIS, JOHN BENJAMIN, one of the minor classic poets of Germany, was born at Zittau on the last day of the year 1746. Though he had no other instruction than what the gymnasium of his native place afforded (for his father, who was a clothmaker, had suffered so much in his circumstances by the war, as to be unable to send him elsewhere), his natural abilities, seconded by a happy memory, stood him greatly in lieu of a regular classical education. Having made himself a complete master of Latin, he went to Leipzig with the intention of applying himself to the study of physic, but soon desisted from it as one for which he had no relish, and applied himself to poetry. At the recommendation of some of his friends, but far more out of necessity, he published a volume of poems in 1766. These first proofs of his poetical talent obtained for him the encouraging notice of Gellert, Weisse, and Oeser; the last-mentioned of whom interested himself warmly in his success, and earnestly recommended him to Gleim, who was afterwards his truest patron. In 1770 he was invited to undertake the editorship of the 'Hamburg Correspondent;' but he soon relinquished the office, which, alluring as it appeared at first, soon proved too irksome for him. While at Hamburg however he became acquainted with Lessing, who exerted himself to serve him, and obtained for him the situation of stage-poet in Seyler's company; but his nervousness and ill state of health soon compelled him to give it up. He now determined to avail himself of the generous proposal which Gleim had previously made him, to take up his residence with him, and make his house a permanent home. By Gleim he was welcomed as if rather conferring an obligation than receiving one; and thus suddenly placed in ease and comfort, and in the society of such men as Jacobi and Lichtwer, nothing further was left him to wish for, except that he might continue to enjoy his happiness. Unfortunately he became subject to a spitting of blood, which carried him off, September 30th, 1772, in the twenty-fifth year of his age.

In the favourable circumstances in which he was latterly placed, there is no doubt but that, had longer life been granted him, he would have distinguished himself among the writers at the close of the eighteenth century. The productions he left are to be considered merely as the blossoms of poetical talent. The principal ones among them are his satires, fables, and tales, and poetical epistles; and they afford proof not only of literary talent, but of the excellence of his moral character.

MICHAELMAS, the feast of St. Michael the archangel, 29th of September. Brady says it was first established in 487. Michaelmas-day is one of the regular periods, in this country, for settling rents; and an old custom is still in use of having a roast goose to dinner on that day, probably because geese are at this time most plentiful and in the highest perfection. Beckwith, in the last edition of the 'Jocular Tenures,' p. 223, says, 'Among other services, John de la Hay was bound to render to William Barnaby, lord of Lastres in the county of Hereford, for a parcel of the demesne lands, one goose fit for the lord's dinner on the feast of St. Michael the archangel. And this as early as the tenth year of king Edward the Fourth.' ('Lastres,' *Rot. Cur.*, 10 Edw. IV.)

Martin, in his 'Description of the Western Islands of Scotland,' p. 213, speaking of the Protestant inhabitants of Skie, says, 'They observe the festivals of Christmas, Easter, Good Friday, and that of St. Michael's. Upon the latter they have a cavalcade in each parish, and several families bake the cake called St. Michael's bannock.'

(Brady's *Clavis Calendaria*, vol. ii., p. 175-180; Brand's *Popular Antiquities*, 4to. ed., vol. i., p. 291-298.)

MICHAUX, ANDRÉ, was a French botanist, who visited Syria, Persia, and North America, at the latter part of the last century, in all which countries he made considerable collections of dried plants. He is chiefly known as the author of a valuable account of the oaks of North America, published in folio, at Paris, in 1801, and of the 'Flora Boreali-Americana,' which appeared in 1803, in two volumes 8vo. Of the latter work he is said to have been less the author than the late Professor Louis Claude Richard.

MICHAUX, FRANÇOIS ANDRÉ, son of André, was employed by the French government to explore the forests of North America, with a view to the introduction into Europe of the valuable timber-trees of that country. For this purpose he made three voyages to the United States, during which he succeeded in sending to France large quantities of seeds. His principal work is the 'Histoire des Arbres forestiers de l'Amerique Septentrionale,' in 3 vols. large 8vo., Paris, 1810-1813; this is an excellent account of the principal North American forest trees, abounding in valuable information as to their geographical distribution and botanical distinctions, and the uses and qualities of their timber. Besides these, he published a treatise 'On the Naturalization of Forest Trees in France,' 8vo., Paris, 1805; 'Journey to the West of the Alleghany Mountains,' 8vo., Paris, 1804; and 'A Notice of the Bermudas,' 4to., Paris, 1806.

MICHELOZZI, MICHELOZZO, an eminent Florentine sculptor and architect of the sixteenth century, was a pupil of Donatello, and was patronised by Cosmo de' Medici, to whom he was so attached, that on the latter being banished, in 1433, he chose to follow him. It was for Cosmo that he erected the edifice since denominated the Palazzo Riccardi at Florence, a noble monument of the older Florentine style, simple even to severity, yet possessing an air not only of grandeur, but of magnificence. The façade consists of a lofty rusticated basement, with comparatively small apertures, above which are two ranges of large arched windows, seventeen on a floor, and each divided into two lesser arches resting on a central column. The whole is crowned by a very rich cornice. The interior court has upper and lower porticos or galleries, with arches resting upon columns, and with an enriched frieze between the first and second arcades. He also greatly improved the court of the Palazzo Vecchio, originally built by Arnolfo, and which is in a rich though somewhat fanciful style inclining to Gothic. Among his other works at Florence is the Palazzo Tornabuoni, now Corsi; and in the neighbourhood of that city the villas Cafaggiuolo and Carregi; also a palace at Fiesole, for Giovanni de' Medici, son of Cosmo I. During the time of his residence at Venice he made designs for many public and private buildings in that city, and erected there the celebrated library in the convent of San Giorgio. He was likewise employed by his patron Cosmo in enlarging and embellishing a palace at Milan, bestowed on him by Ludovico Sforza. His last work was designing and superintending the execution of the monumental chapel of the Annunciation, erected by Piero de' Medici in honour of Cosmo, in the Chiesa dei Servi, at Florence.

Michelozzo died at the age of sixty-eight, but the precise time of his decease is not known—probably it was about 1470.

MICHIGAN, a portion of the United States, which hitherto has been governed as a territory. The peninsular part of it will soon form a member of the Union, if it has not already been constituted an independent state; and the western part will remain a territorial government. The peninsula lies between 41° 35' and 45° 50' N. lat., and between 82° 35' and 86° 50' W. long. This part, which will form the state, is about 280 miles long, and on an average 150 miles wide, and is stated to have an area of 34,000 square miles, or about 5000 square miles more than the area of Scotland. Michigan is a peninsula, the western side of which is washed by Lake Michigan in all its length, or about 280 miles. The strait of Michilimackinac, which unites Lake Michigan with Lake Huron, and the north-western portion of the last-mentioned lake, surround the peninsula on the north. On the east extends Lake Huron, as far south as 43° N. lat. where it forms a deep bay, called Saginaw Bay, and constitutes, from the Strait of Michilimackinac to the outlet of the river St. Clair, a coast line of more than 260 miles. South of 43° N. lat. the boundary is formed by the river St. Clair for about 30 miles, and by the lake of St. Clair for about the same length. The river Detroit then becomes the boundary to its embouchure in Lake Erie, a distance of

about 30 miles. Lake Erie washes the eastern shores of Michigan for about 40 miles. In the south the peninsula is divided by an imaginary line from the states of Ohio and Indiana. The boundary-line of Ohio runs along $41^{\circ} 35'$ N. lat. for about 80 miles, and that of Indiana along $41^{\circ} 45'$ N. lat. for about 110 miles.

Surface and Soil.—The interior of the peninsula forms a plain which has generally a level surface, but in some districts is undulating or intersected with low hills. This tract is probably about 200 feet above the lakes, and the surface of the lakes is nearly 600 feet above the sea-level, so that the greatest part of Michigan is probably about 800 feet above it. The highest land seems to traverse the peninsula towards its southern extremity in a south-west and north-east direction, and to terminate on the east of Saginaw Bay with the smaller peninsula of Sanilac. The surface of this part is more undulating than other parts, and intersected by a great number of small lakes. The soil is said to be rather fertile. The slope of this high land towards the lakes Erie and St. Clair, and the straits of Detroit and St. Clair, is long and hardly perceptible. This is probably the most fertile district of the country; it contains little prairie land, except on the alluvial tracts near the mouths of the rivers and along the lakes, which are in some parts marshy but fertile. Nearly the whole of the remainder of the country is covered with trees of a heavy growth. The slope towards Saginaw Bay along Saginaw river and its numerous branches is of a similar character: but the peninsula of Salinac has a poor soil and is mostly sandy. The larger peninsula, between Lake Huron and Lake Michigan, is less known. It is however certain that it contains no mountains, nor even high hills. A great portion of it is prairie-land, intersected with numerous swamps, at least in the southern districts which have been explored. The shores of both the great lakes are poor and sandy; and along the shore of Lake Michigan there are sandy eminences, formed near the mouths of the numerous small rivers which join the lake, by the action of their current against the swell of the lake: the adjacent tracts are of very inferior fertility.

Rivers.—As the rivers of the peninsula descend from the table-land to the great lakes, they have a short course. On the table-land they run slowly, but on the declivity their course is accelerated and interrupted by rapids. The most important are St. Joseph's river and Saginaw. St. Joseph's river falls into Lake Michigan, not far from its southern extremity, after a winding course of about 200 miles. Though rather rapid, it is said to be navigable for boats through nearly the whole of its winding course. The Saginaw river is formed by a great number of branches, which descend from the table-land lying to the east, south, and west of the depression in which it flows, and which may be considered as a prolongation of Saginaw Bay. Some of these branches flow fifty miles before they unite. After their union, the river takes the name of Saginaw, and is navigable for boats to its mouth, a distance of twenty-five miles. The rivers St. Clair and Detroit, as well as the lakes of Michigan, Huron, St. Clair, and Erie, are noticed under CANADA (p. 208, 209).

Climate.—The climate of this country is severe. The winter generally begins in the middle of November and lasts to the middle of March. The ice on the rivers and borders of the lake is strong enough to admit travelling on sledges. Though situated on both sides of 45° N. lat., its climate resembles that of southern Sweden (57° N. lat.). This circumstance is mainly to be attributed to the elevation of the surface, and also to its not being sheltered by any range of mountains against the cold northern and north-western winds which blow over the immense plains that stretch northward to the shores of the Polar Sea. The surrounding lakes, though large, are still too small to moderate in any sensible degree the coldness of these winds. Lake St. Clair is frozen over every year from December to February. The summers are never hot, but subject to considerable changes. In the hottest days the thermometer rises to 70° , but in the evening and morning it is as low as 46° . The climate is rather dry, and the quantity of snow which falls not considerable.

Productions.—Wheat, maize, and potatoes are grown to a great extent; oats and buckwheat are not so extensively cultivated. Other vegetables thrive very well. The country along the Strait of Detroit is famous for its orchards, which the French settlers have planted, and which are extensive

and well managed. A great quantity of cider is exported. The most common trees are ash, beech, cedar, cherry-trees, elm, hickory, maple, oak, pine, poplar, aspen, and walnut. Around the lakes of the table-land and near the mouth of some rivers large tracts are covered with the wild rice (*Zizania aquatica*), on which immense flocks of water-fowl of different species feed. Of domestic animals cows are most numerous. The wild animals are the elk or moose-deer, deer, wolves, foxes, wild cats, otters, martens, racoons, opossums, squirrels of different kinds, and musk-rats. Beavers are only found on the rivers which fall into Lake Michigan. Fish abound in the lakes and rivers, but not in Lake Michigan. Wild turkeys and pigeons are abundant.

Inhabitants.—There are few settlements of the whites north-west of a line drawn from the mouth of St. Joseph's river to that of the Saginaw. The whole tract lying north of it is chiefly in possession of the aboriginal tribes of the Ottawas and Miamis, who, with some Pottowatomis and Chippewas, have in some places villages within the range of the country inhabited by the descendants of Europeans. These Indians generally cultivate maize, and some of them wheat and vegetables; they also raise horses, cattle, hogs, and poultry. The population of these tribes may amount to about 9000. That of the whites was estimated in 1810 at 4700, in 1820 at 10,000, and in 1830 it amounted to 31,670 souls, and according to an enumeration presented to Congress in 1834, it amounted to upwards of 90,000 within the limits of the proposed state, which is a greater relative increase than any other state or territory in the Union has had in the same time. There are a few coloured individuals.

Political Division and Towns.—The country settled by the whites is divided into 35 counties. The only place of importance is Detroit, built not far from the efflux of the river of the same name from Lake St. Clair. It is the seat of government, and contains above 3000 inhabitants, mostly of French origin: it is also the principal deposit for the cider, grain, and furs, which are sent from this place mostly to Cleveland in Ohio, and to Maldon in Upper Canada. It also carries on a considerable trade with the Indians. Mackinac, or Mackinaw, on the island of Michilimackinac (about nine miles in circuit), contains about 100 houses, and has a good harbour. It is the great place of resort for the Indians both for the sale of their furs and for receiving the annuities paid them by the United States. There is daily communication by steam-boats between Detroit and Buffalo in New York, a distance of above 300 miles. Many of the oldest inhabitants are of French extraction, but the largest part of the population consists of emigrants from New England.

History.—Early in the seventeenth century the French penetrated into this country from Quebec. In 1670 they founded Detroit. In 1783 Michigan was included in the limits of the United States, but not actually given up by the British until 1796. In 1805 it was formed into a territory. (Darby's *View of the United States*; &c.)

MICHIGAN, Lake. [CANADA.]

MICIPPA. [MAIDÆ, vol. xiv., p. 300.]

MICKLE, WILLIAM,* was born in the year 1734, at Langholm in Dumfriesshire, where his father was a Presbyterian minister. At the age of sixteen he was sent to the counting-house of a relation, who was a brewer, and remained there five years. He afterwards set up business on his own account, but failed, it is said, because he devoted those hours to his poetical studies, which should have been dedicated to business. He subsequently became corrector of the Clarendon Press in Oxford, and though several of his juvenile poems had been printed, his name remained unknown to the public till the publication of an elegiac ode called 'Pollio,' in 1765. This was followed in 1767 by a poem in imitation of Spenser, called 'The Concubine,' published with many corrections and additions ten years afterwards under the title of 'Sir Martyn.' He also wrote, besides several other poems, a 'Letter to Dr. Harwood,' against the Arian views; an attack on Deism, called 'Voltaire in the Shades;' and a tragedy entitled the 'Siege of Marseilles,' which was refused by Garrick, Harris, and Sheridan in succession, and never produced. In 1775 came out his translation of Camoens's 'Lusiad,' which had occupied him five years. Governor Johnstone, his patron, having been

* Sometimes called William Julius Mickle, but the second name was merely assumed by the author himself.

appointed commander of the Romney man-of-war, took him out to Lisbon, where he was appointed joint-agent for the prizes that might be taken in an expected cruise. His translation procured him much respect among the Portuguese, and he was admitted a member of the royal academy, of which Prince Don John of Braganza was president. A poem called 'Almada Hill' was a result of his residence at Lisbon. After Mickle's return to London with Governor Johnstone, he wrote several pieces both in prose and verse, the last of which was 'Eskdale Braes,' a ballad. He died at Wheatly in Oxfordshire, in 1789.

His translation of the 'Lusiad' has been severely censured on account of the liberties taken with the original, and the unwarranted diffuseness of the translation. Mickle's poems as a whole are worth little, indeed so little, that we may wonder how they acquired the small celebrity which they have attained. A ballad by Mickle entitled 'Cumnor-Hall' is not without merit; it furnished the idea of Sir W. Scott's 'Kenilworth,' and is printed in the introduction to that work in the late complete edition of Scott's novels.

MICO, or Fair Monkey, one of the common names for that species of *Ouistiti* (*Hapale* of Illiger) known to zoologists as the *Jacchus argentatus*, Geoff., *Simia argentata*, Linn. It is a very pretty little species, perhaps the prettiest of the genus. [JACCHUS.] The head is small and round, the face and hands of a deep flesh-colour; indeed the face and ears are of so lively a vermilion, that the animal, when in full health, looks almost as if it had been painted with that colour. The body is covered with long silvery-white hair, and the tail is of a shining dark chestnut, sometimes almost black.

MICROCEBUS, M. Geoffroy's name for a form among the *Lemuridae*: *Lemur* (Galago) *Guineensis*. Locality.—The river Amazon: Para.

MICRODACTYLUS. [GARIAMA.]

MICROGLOSSUS. [PSITTACIDÆ.]

MICROMETER, the term generally applied to contrivances for measuring small spaces or angles with great accuracy or convenience.

The word is not applied to some artifices for subdividing the graduations of an astronomical instrument (for these see *VERNIER*), nor when a magnified portion of a subsidiary arc is used, which may be best considered under the head of *SECTOR*, *ZENITH SECTOR*, though they come properly under the definition. We shall follow the usual meaning of the term.

1. *Wire Micrometer*.—When the rays from any bright object fall upon a convex lens, an inverted image of the object is formed, which may be viewed by the eye-piece as if it were a material body. If a fine wire or spider's web be stretched across the telescope tube at the place where the image is formed, this too will be seen distinctly through the eye-piece. Instead of fixing the wire to the telescope tube, it is stretched across a sliding-piece, which is moved by a screw perpendicularly to the length of the telescope, and can thus be made to measure the image in terms of the revolutions and parts of the screw. The head of the screw is divided, and there is an index by which the parts are read off. A little tongue passing over the notches of a plate notes the whole number of revolutions.

An English gentleman named Gascoigne seems first to have applied this principle to practice, but he unfortunately lost his life in the great civil war; and though his telescope fell into Townley's hands, and was used by him, the construction does not seem to have been generally known until it was re-invented by Auzout. Different improvements were gradually made nearly up to the present time. The plate carrying the wire is drawn by the screw, and held back by springs, which prevent any lost time. A micrometer of this kind is now generally applied to circles, transits, and theodolites, in addition to the fixed wires, which of course are always necessary. There are two verifications: first, the ascertaining the value of a revolution of the screw; and secondly, determining the reading of the screw-head when the moveable wire coincides with the fixed wire. In a circle or theodolite the micrometer wire is placed upon a sharp distant object, and the divided limb read off. The screw is turned through several revolutions, and the object is again bisected by moving the whole instrument by its tangent screw, and the divided limb read off a second time. We have then the same angle measured in revolutions of the screw and in the divisions of the instrument, and by a simple proportion have the value of a revo-

lution and of a part. With a transit, the passage of Polaris over the micrometer wire is observed after successive revolutions of the screw. The angular motion of Polaris for the intervals is computed from the polar distance, and thus the value in arc obtained for a revolution of the screw. To determine the zero position of the micrometer wire, the moveable wire is brought to touch the fixed wire, first on one side, and then on the other, and the screw-head read off each time. The mean of the two readings will be that when the two wires are exactly superimposed.

The *position wire micrometer* has lately come very much into use for observations of double stars, and is the wire micrometer proper for equatorials. In this construction there are two wires parallel to each other, each moveable by its own screw: the whole apparatus can also be turned round in the plane of the wires, so as to place the wires in any direction, the angle round which it is turned being read off by two verniers upon a small circle called the position circle. In measuring a double star the wires are brought near each other, and the apparatus turned round until the two stars are either threaded on one of the wires, or, being placed between them, are judged to lie in the same direction. The division of the micrometer circle is then read off, and the observation in position is made. Now, by the divided circle of the micrometer turn the apparatus round 90°, and the wires will be at right angles to the line joining the two stars. By moving the equatorial, place one wire A on one of the stars, and place the other wire B by its screw, on the second star. Read off the screw-head of B, and then place A on the second star by moving the equatorial, and B on the first by moving its screw, and read off the revolutions and parts of B. The difference of the two readings of B will give, in revolutions and parts of the screw, twice the angle between the two stars. The process may be repeated, keeping B fixed and moving A. Before or after a series of observations the zero or index error of the position circle should be ascertained. Place the instrument nearly in the meridian, and make a star run along one of the wires from end to end. Read and note the position circle, which should mark 90° and 270°, and the difference from this is the correction to be applied to all the angles of position observed during the evening. The value of a revolution of the screw may be determined by separating the two wires a given number of revolutions, and observing a series of transits of known stars over them. As large equatorials are always carried by a clock movement, we should recommend fixing the *position micrometer* upon a *slipping-piece*, by which a small motion up or down or to the right or left can be given to the wires without meddling with the clock or the equatorial. With this apparatus the measurement of double stars is perfectly easy. The wire micrometer requires illumination for seeing the wires, and the light thus admitted often obliterates faint and ill-defined objects. For a description of the position micrometer and its application to the measurement of double stars, see De Morgan's *Companion to Maps of the Stars*, Appendix.

The micrometer microscope, for reading off the divisions of graduated circles, depends upon the same principle as the wire micrometer. An enlarged image of the divisions of the limb of the circle is formed, and this image is measured by the revolutions and parts of a screw. [CIRCLE.]

2. The *divided object-glass micrometer* and *heliometer*. If an object-glass be cut across so as to form two semicircles, and the semilenses be separated by sliding one beyond the other, each portion will form its proper image, and these will retreat from each other as the semilenses are moved. The semilenses are mounted on slides, and the quantity of separation read off upon a scale. In Bessel's heliometer, the most magnificent and most perfect instrument of this class, the focal length of the object-glass is eight French feet, and the aperture nearly six French inches. A description and plate will be found in the *Astronomische Nachrichten*, No. 189. The only objection which can be made to this species of micrometer, besides the extreme difficulty of constructing it, is, that stars are not seen so round and well defined as in an entire object-glass. Bessel's measures of double stars are however, so far as we can judge, the most accurate that have yet been made. Suppose a double star is to be measured with the heliometer: the whole of the object end is turned round, until four stars appear in a right line, and the semilenses are separated until the stars appear to be exactly at the same distance from each other, when

the scale is read off. The semilenses are then shifted in a contrary direction, sliding the two images over each other, until they again appear to be at equal distances, and the scale is again read off. The separation of the scale is four times the angular distance between the stars. There is a position circle, on which the direction of the stars is read off. In measuring the diameters of the sun, planets, &c., the two images are made to touch on opposite sides; and in observations of Halley's comet it was made to coincide with the neighbouring stars. The divided object-glass micrometer is on the same principle as the heliometer; a cap containing the divided lenses is placed over the object-glass of the telescope. A similar micrometer may be obtained by dividing one of the lenses of an eye-piece; and it seems probable that, with large telescopes, this micrometer may be of considerable use in measuring small angles. There is a good deal of colour in the images, but not at the point of contact. Micrometers of this class require no illumination.

3. *Reticules and circular micrometer.* The micrometers hitherto described are applied to the *accurate* measures of small angles; the present class, though very useful in certain cases, are of much lower pretensions. The reticule, or diaphragm, as it is sometimes called, is any fixed arrangement of wires or bars which can be applied to a telescope for the purpose of measurement. They are chiefly used when an object will not admit of illumination, or where the astronomer has no accurately divided instrument at his disposal, or, as in the case La Caille at the Capo of Good Hope, when the object is to fix approximately a greater number of stars than could be done in the same time with ordinary instruments. Suppose a cross like an X or V to be cut out of brass-plate and inserted in the principal focus of a telescope with the axis of the letter in a meridian. A star in passing through the field is occulted at its passage behind each of the bars, and the time noted. The *interval* will show, by an easy calculation, how far it passes from the vertex; and the *mean* of the times, the moment when it passes the axis of the diaphragm. If the true position of any one star so passing is known from any other source, all the other stars can be thus determined differentially with respect to it. The method is not very accurate, but may often be applied advantageously and with very small instrumental means. If a fine wire be drawn perpendicular to the axis, and a bright star, observed with illumination, made to run along the wire, the axis of the diaphragm can be set in a meridian, and that is the only verification necessary. The computation in declination will be least if the angle between the bars is such that the base of the triangle is equal to its altitude. This reticule is very convenient for mapping, if placed in the meridian, or for cometary observation, if the telescope is mounted as an equatorial, however rudely.

The circular micrometer was introduced, we believe, by Olbers, and perfected by Fraunhofer (*Astron. Nachricht.*, iv. 22), and is much less known and used in this country than it deserves. A metal ring is set in the centre of a perforated glass-plate, and the outer and inner edge of the ring is turned true. The plate is fixed in the focus of a telescope, and the appearance is that of a ring suspended in the heavens. The telescope is pointed, and the observer notes the time when a star disappears at the outer ring, re-appears on the inner ring, disappears again, and finally re-appears. If two stars be thus observed, it is clear that when a mean is taken of the disappearances and re-appearances of each, that the difference between the two means will be the difference of right ascension between the two stars, and therefore that if one be known, the other is determined. Again, if the diameter of the ring has been determined, and the declination of the stars nearly known, the time of describing the chord of the ring will give, by an easy computation, the distance of the chord from the centre, and that the more accurately the smaller the chord described. The sum or difference of these two distances is the difference of the stars in declination. The computation of the second star with its approximate declination may be repeated if the stars are near the pole. It will be seen that nothing is required for the circular micrometer, but the power of fixing the telescope for a few minutes until a known star passes the field, and that no illumination is required. It is especially the apparatus for determining the place of a faint comet or planet, and in the hands of Olbers, Harding, and many other German astronomers, has

been of infinite use in cometary astronomy and in the discovery and observation of the small planets. When the comet has a large motion, or when the position of the star is so low as to require attention to the difference of refraction, the computation is a little more complicated, but generally scarcely any computation is required, and the results, in right ascension at least, are good. The observations at the inner edge of the ring are to be preferred. When however the object will bear illumination and the astronomer possesses a telescope so mounted that he can apply a wire micrometer to it, the results from this are incomparably more accurate, and the reticule above mentioned is certainly better for determining declination. Fraunhofer afterwards (*Astronom. Nach.*, iv. 43) proposed another ring and reticule micrometer. He cut a series of rings or lines upon a piece of plane glass which he placed in the principal focus of the object-glass, and then by a side lamp illuminated the rings, leaving the rest of the field dark. It is evident that for certain observations this micrometer would have great advantages.

There are many other micrometers, but they are not in such general use as to demand any notice here. The reader will find them very fully and elaborately described in Pearson's *Astronomy*, vol. ii., p. 126 to 272 inclusive.

MICROPO'GON, M. Temminck's name for a genus of Scansorial Birds which has the general structure of *Bucco*. The gape however is smooth. The three first quills only are graduated. Mr. Swainson arranges it under the '*Bucconinae*,' or '*Barbuts*,' a subfamily of his *Picidae*.

MICRO'PTERUS, a name assigned by MM. Quoy and Gaimard to a genus of *Anatidae*, remarkable for the shortness of their wings.

Two species are recorded, viz. *Micropterus brachypterus* (Quoy and Gaim., *Oidemia Patachonica*, King, *Anas brachyptera*, Lath., *Racehorse* of Cook and Byron, and *Steamer-duck* of King), and *Micropterus Patachonicus*, King, which is smaller in the body than the first, and is able to fly.

Description of the first-named Species.—Above lead-colour, inclining to grey; abdomen whitish; the beauty-spot on the wings white, at the bend a blunt spur; bill yellow, the nail black; legs fuscous yellow. Length from tip of the bill to end of tail, 40 inches; of bill, 3; of wing, from carpal joint to apex of second quill feather, 11; of tail, 5; of tarsi, 2½. (King.)

Habits, Food, &c.—Captain Phillip Parker King, R.N., who has described both species, one in the *Zool. Journal*, and the second in the *Zool. Proceedings*, first fell in with the larger species at Eagle Bay, beyond Cape San Isidro (Point Shut-up of Byron), in the Strait of Magalhaens. 'Here,' writes Captain King, 'we saw, for the first time, that most remarkable bird the Steamer-duck. Before steam-boats were in general use, this bird was denominated, from its swiftness in skimming over the surface of the water, the 'racehorse,' a name which occurs frequently in Cook's, Byron's, and other voyages. It is a gigantic duck, the largest I have met with. It has the lobated hind toe, legs placed far backwards, and other characteristics of the oceanic ducks. The principal peculiarity of this bird is the shortness and remarkably small size of the wings, which, not having sufficient power to raise the body, serve only to propel it along, rather than through the water, and are used like the paddles of a steam-vessel. Aided by these and its strong broad-webbed feet, it moves with astonishing velocity. It would not be an exaggeration to state its speed at from twelve to fifteen miles an hour. The peculiar form of the wing and the short rigid feathers which cover it, together with the power this bird possesses of remaining a considerable time under water, constitute it a striking link between the genera *Anas* and *Aptenodytes*. It has been noticed by many former navigators. The largest we found measured forty inches from the extremity of the bill to that of the tail, and weighed thirteen pounds; but Captain Cook mentions, in his second voyage, that the weight of one was twenty-nine pounds. It is very difficult to kill them, on account of their wariness and thick coat of feathers, which is impenetrable by anything smaller than swan-shot. The flavour of their flesh is so strong and fishy, that at first we killed them solely for specimens. Five or six months however on salt provisions taught many to think such food palatable, and the seamen never lost an opportunity of eating them. I have preferred these ducks to salt beef, but more as a preventive against scurvy than from liking their taste. I am averse to altering names,

particularly in natural history, without very good reason; but in this case I do think the name of "steamer" much more appropriate and descriptive of the swift paddling motion of these birds than that of "race-horse." I believe, too, the name of "steamer" is now generally given to it by those who have visited these regions.

The same author informs us that *Pecten vitreus*, whose shell is found attached to the leaves of *Fucus giganteus*, together with other *Mollusca*, is the food of the steamer-ducks *M. brachypterus* and *M. Patuchonicus*.

(Narrative of the Surveying Voyages of H. M. S. Adventure and Beagle, vol. i.)

Race-horse, or Steamer duck (*Micropterus brachypterus*).

Micropterus comes very near to *Microptera*, Gravenhorst's name for a genus of coleopterous insects, and to *Microptère* of Lacépède, who uses the term to designate a genus of Acanthopterygious fishes.

MICROPUS, Mr. Swainson's name for the first genus of his Brachypodinae, the first subfamily of the *Merulidæ*, according to his arrangement. [MERULIDÆ.]

Example, *Micropus chalconcephalus*; *Iros chalconcephalus*, Temm.

Description.—*Male*.—The whole head covered with a sort of hood of metallic black with violet reflections; the neck, the shoulders, the back, and wings dull gray or lead colour; breast deep gray, which becomes brighter on the other lower parts of the body; wings black, but the secondaries gray, bordered with whitish on the exterior barbs; tail gray, with a transverse black band, and terminated with a broad white border. Length six inches four lines. *Female*: less lively in colour.

Locality, Java, where Van Hasselt found it in the wild and woody district of Bantam.

Micropus chalconcephalus (male).

MICROSCOPE, the name of an instrument for enabling the eye to see distinctly objects which are placed at a very short distance from it, or to see magnified images of small objects, and therefore to see smaller objects than would otherwise be visible. The name is derived from the two Greek words, expressing this property, *μικρός*, *small*, and *σκοπεῖν*, *to see*.

So little is known of the early history of the microscope, and so certain is it that the magnifying power of lenses must have been discovered as soon as lenses were made, that there is no reason for hazarding any doubtful speculations on the question of discovery. We shall proceed therefore at once to describe the simplest forms of microscopes, to explain their later and more important improvements, and finally to exhibit the instrument in its present perfect state.

In doing this we shall assume that the reader is familiar with the information contained in the articles LIGHT, LENS, ACHROMATIC, ABERRATION, and the other subdivisions of the science of Optics which are treated of in this work.

The use of the term *magnifying* has led many into a misconception of the nature of the effect produced by convex lenses. It is not always understood that the so-called magnifying power of a lens applied to the eye, as in a microscope, is derived from its enabling the eye to approach more nearly to its object than would otherwise be compatible with distinct vision. The common occurrence of walking across the street to read a bill is in fact magnifying the bill by approach; and the observer, at every step he takes, makes a change in the optical arrangement of his eye, to adapt it to the lessening distance between himself and the object of his inquiry. This power of spontaneous adjustment is so unconsciously excited, that unless the attention be called to it by circumstances, we are totally unaware of its exercise.

In the case just mentioned the bill would be read with eyes in a very different state of adjustment from that in which it was discovered on the opposite side of the street, but no conviction of this fact would be impressed upon the mind. If however the supposed individual should perceive on some part of the paper a small speck, which he suspects to be a minute insect, and if he should attempt a very close approach of his eye for the purpose of verifying his suspicion, he would presently find that the power of natural adjustment has a limit; for when his eye has arrived within about ten inches, he will discover that a further approach produces only confusion. But if, as he continues to approach, he were to place before his eye a series of properly arranged convex lenses he would see the object gradually and distinctly increase in apparent size by the mere continuance of the operation of approaching. Yet the glasses applied to the eye during the approach from ten inches to one inch, would have done nothing more than had been previously done by the eye itself during the approach from fifty feet to one foot. In both cases the magnifying is effected really by the approach, the lenses merely rendering the latter periods of the approach compatible with distinct vision.

A very striking proof of this statement may be obtained by the following simple and instructive experiment. Take any minute object, a very small insect for instance, held on a pin or gummed to a slip of glass; then present it to a strong light, and look at it through the finest needle-hole in a blackened card placed about an inch before it. The insect will appear quite distinct, and about ten times larger than its usual size. Then suddenly withdraw the card without disturbing the object, which will instantly become indistinct and nearly invisible. The reason is, that the naked eye cannot see at so small a distance as one inch. But the card with the hole having enabled the eye to approach within an inch, and to see distinctly at that distance, is thus proved to be as decidedly a magnifying instrument as any lens or combination of lenses.

This description of magnifying power does not apply to such instruments as the solar or gas microscope, by which we look not at the object itself, but at its shadow or picture on the wall; and the description will require some modification in treating of the compound microscope, where, as in the telescope, an image or picture is formed by one lens, that image or picture being viewed as an original object by another lens.

It is nevertheless so important to obtain a clear notion of the real nature of the effect produced by a lens applied to the eye, that we will adduce the instance of spectacles to render the point more familiar. If the person who has

been supposed to cross the street for the purpose of reading a bill had been aged, the limit to the power of adjustment would have been discovered at a greater distance, and without so severe a test as the supposed insect. The eyes of the very aged generally lose the power of adjustment at a distance of thirty or forty inches instead of ten, and the spectacles worn in consequence are as much magnifying glasses to them as the lenses employed by younger eyes to examine the most minute objects. Spectacles are magnifying glasses to the aged because they enable such persons to see as closely to their objects as the young, and therefore to see the objects larger than they could themselves otherwise see them, but not larger than they are seen by the unassisted younger eye.

In saying that an object appears larger at one time, or to one person, than another, it is necessary to guard against misconception. By the apparent size of an object we mean the angle it subtends at the eye, or the angle formed by two lines drawn from the centre of the eye to the extremities of the object. In *figure 1*, the lines *A E* and *B E* drawn

from the arrow to the eye form the angle *A E B*, which, when the angle is small, is nearly twice as great as the angle *C E D* formed by lines drawn from a similar arrow at twice the distance. The arrow *A B* will therefore appear nearly twice as long as *C D*, being seen under twice the angle, and in the same proportion for any greater or lesser difference in distance. The angle in question is called the angle of vision, or the visual angle.

The angle of vision must however not be confounded with the angle of the pencil of light by which an object is seen, and which is explained in *figure 2*. Here we have

drawn two arrows placed in relation to the eye as before, and from the centre of each have drawn lines exhibiting the quantity of light which each point will send into the eye at the respective distances.

Now if *E F* represent the diameter of the pupil, the angle *E A F* shows the size of the cone or pencil of light which enters the eye from the point *A*, and in like manner the angle *E B F* is that of the pencil emanating from *B*, and entering the eye. Then, since *E A F* is double *E B F*, it is evident that *A* is seen by four times the quantity of light which could be received from an equally illuminated point at *B*; so that the nearer body would appear brighter if it did not appear larger; but as its apparent area is increased four times, as well as its light, no difference in this respect is discovered. But if we could find means to send into the eye a larger pencil of light, as for instance that shown by the lines *G A H*, without increasing the apparent size in the same proportion, it is evident that we should obtain a benefit totally distinct from that of increased magnitude, and one which is in some cases of even more importance than size in developing the structure of what we wish to examine. This, it will be hereafter shown, is sometimes done; for the present, we wish merely to explain clearly the distinction between apparent magnitude, or the angle under which the object is seen, and apparent brightness, or the angle of the pencil of light by which each of its points is seen, and with these explanations we shall continue to employ the common expressions magnifying glass and magnifying power.

The magnifying power of a single lens depends upon its focal length, the object being in fact placed nearly in its principal focus, or so that the light which diverges from

each point may, after refraction by the lens, proceed in parallel lines to the eye, or as nearly so as is requisite for distinct vision. In *fig. 3*, *A B* is a double convex lens, near

which is a small arrow to represent the object under examination, and the cones drawn from its extremities are portions of the rays of light diverging from those points and falling upon the lens. These rays, if suffered to fall at once upon the pupil, would be too divergent to permit their being brought to a focus upon the retina by the optical arrangements of the eye. But being first passed through the lens, they are bent into nearly parallel lines, or into lines diverging from some points within the limits of distinct vision, as from *C* and *D*. Thus altered, the eye receives them precisely as if they emanated from a larger arrow placed at *C D*, which we may suppose to be ten inches from the eye, and then the difference between the real and the imaginary arrow is called the magnifying power of the lens in question.

From what has been said it will be evident that two persons whose eyes differed as to the distance at which they obtained distinct vision, would give different results as to the magnifying power of a lens. To one who can see distinctly with the naked eye at a distance of five inches, the magnifying power would seem and would indeed be only half what we have assumed. Such instances are however rare; the focal length of the eye usually ranges from six to twelve or fourteen inches, so that the distance we first assumed of ten inches is very near the true average, and is a convenient number, inasmuch as a cipher added to the denominator of the fraction which expresses the focal length of a lens gives its magnifying power. Thus a lens whose focal length is one-sixteenth of an inch is said to magnify 160 times.

When the focal length of a lens is very small it is difficult to measure accurately the distance between its centre and its object. In such cases the best way to obtain the focal length for parallel or nearly parallel rays is to view the image of some distant object formed by the lens in question through another lens of one inch solar focal length, keeping both eyes open and comparing the image presented through the two lenses with that of the naked eye. The proportion between the two images so seen will be the focal length required. Thus if the image seen by the naked eye is ten times as large as that shown by the lenses, the focal length of the lens in question is one-tenth of an inch. The panes of glass in a window, or courses of bricks in a wall, are convenient objects for this purpose.

In whichever way the focal length of the lens is ascertained, the rules given for deducing its magnifying power are not rigorously correct, though they are sufficiently so for all practical purposes, particularly as the whole rests on an assumption in regard to the focal length of the eye, and as it does not in any way affect the actual measurement of the object. To calculate with great precision the magnifying power of a lens with a given focal length of eye, it is necessary that the thickness of the lens be taken into the account, and also the focal length of the eye itself.

We have hitherto considered a magnifying lens only in reference to its enlargement of the object, or the increase of the angle under which the object is seen. A further and equally important consideration is that of the number of rays or quantity of light by which every point of the object is rendered visible. The naked eye, as shown in *fig. 2*, admits from each point of every visible object a cone of light having the diameter of the pupil for its base, and most persons are familiar with that beautiful provision by which in cases of excessive brilliancy the pupil spontaneously contracts to reduce the cone of admitted light within bearable limits. This effect is still further produced in the experiment already described, of looking at an object through a

needle-hole in a card, which is equivalent to reducing the pupil to the size of a needle-hole. Seen in this way the object becomes comparatively dark or obscure; because each point is seen by means of a very small cone of light, and a little consideration will suffice to explain the different effects produced by the needle-hole and the lens. Both change the angular value of the cone of light presented to the eye, but the lens changes the angle by bending the extreme rays within the limits suited to distinct vision, while the needle-hole effects the same purpose by cutting off the rays which exceed those limits.

It has been shown that removing a brilliant object to a greater distance will reduce the quantity of light which each point sends into the eye, as effectually as viewing it through a needle-hole; and magnifying an object by a lens has been shown to be the same thing in some respects as removing it to a greater distance. We have to see the magnified picture by the light emanating from the small object, and it becomes a matter of difficulty to obtain from each point a sufficient quantity of light to bear the diffusion of a great magnifying power. We want to perform an operation just the reverse of applying the card with the needle-hole to the eye—we want in some cases to bring into the eye the largest possible pencil of light from each point of the object.

Referring to *fig. 3*, it will be observed that if the eye could see the small arrow at the distance there shown without the intervention of the lens, only a very small portion of the cones of light drawn from its extremities would enter the pupil; whereas we have supposed that after being bent by the lens the whole of this light enters the eye as part of the cones of smaller angle whose summits are at C and D. These cones will further explain the difference between large and small pencils of light; those from the small arrow are large pencils; the dotted cones from the large arrow are small pencils.

In assuming that the whole of this light could have been suffered to enter the eye through the lens AB, we did so for the sake of not perplexing the reader with too many considerations at once. He must now learn that so large a pencil of light passing through a single lens would be so distorted by the spherical figure of the lens, and by the chromatic dispersion of the glass, as to produce a very confused and imperfect image. This confusion may be greatly diminished by reducing the pencil; for instance, by applying a stop, as it is called, to the lens, which is neither more nor less than the needle-hole applied to the eye. A small pencil of light may be thus transmitted through a single lens without suffering from spherical aberration or chromatic dispersion any amount of distortion which will materially affect the figure of the object; but this quantity of light is insufficient to bear diffusion over the magnified picture, which is therefore too obscure to exhibit what we most desire to see,—those beautiful and delicate markings by which one kind of organic matter is distinguished from another. With a small aperture these markings are not seen at all; with a large aperture and a single lens they exhibit a faint nebulous appearance enveloped in a chromatic mist, a state which is of course utterly valueless to the naturalist, and not even amusing to the amateur.

It becomes therefore a most important problem to reconcile a large aperture with distinctness, or, as it is called, *definition*; and this has been done in a considerable degree by effecting the required amount of refraction through two or more lenses instead of one, thus reducing the angles of incidence and refraction, and producing other effects which will be shortly noticed. This was first accomplished in a satisfactory manner by—

Dr. Wollaston's Doublet,

Fig. 4. invented by the celebrated philosopher whose name it bears; it consists of two plano-convex lenses (*fig. 4*) having their focal lengths in the proportion of 1 to 3, or nearly so, and placed at a distance which can be ascertained best by actual experiment. Their plane sides are placed towards the object, and the lens of shortest focal length next the object.

It appears that Dr. Wollaston was led to this invention by considering that the Achromatic Huyghenian Eye-piece, which will be hereafter described, would, if reversed, possess similar good properties as a simple microscope. But it will be evident when the eye-piece is understood, that the cir-

cumstances which render it achromatic are very imperfectly applicable to the simple microscope, and that the doublet, without a nice adjustment of the stop, would be valueless. Dr. Wollaston makes no allusion to a stop, nor is it certain that he contemplated its introduction, although his illness, which terminated fatally soon after the presentation of his paper, may account for the omission.

The nature of the corrections which take place in the doublet is explained in the annexed diagram (*fig. 5*), where LOL' is the object, P a portion of the pupil, and DD the stop, or limiting aperture.

fig. 5.

Now, it will be observed that each of the pencils of light from the extremities L L' of the object is rendered excentric by the stop, and of consequence each passes through the two lenses on opposite sides of their common axis OP; thus each becomes affected by opposite errors, which to some extent balance and correct each other. To take the pencil L, for instance, which enters the eye at R B R B, it is bent to the right at the first lens, and to the left at the second; and as each bending alters the direction of the blue rays more than the red, and moreover as the blue rays fall nearer the margin of the second lens, where the refraction, being more powerful than near the centre, compensates in some degree for the greater focal length of the second lens, the blue and red rays will emerge very nearly parallel, and of consequence colourless to the eye. At the same time the spherical aberration has been diminished by the circumstance that the side of the pencil which passes one lens nearest the axis passes the other nearest the margin.

This explanation applies only to the pencils near the extremities of the object. The central pencil, it is obvious, would pass both lenses symmetrically; the same portions of light occupying nearly the same relative places on both lenses. The blue light would enter the second lens nearer to its axis than the red, and being thus less refracted than the red by the second lens, a small amount of compensation would take place, quite different in principle and inferior in degree to that which is produced in the excentric pencils. In the intermediate spaces the corrections are still more imperfect and uncertain; and this explains the cause of the aberrations which must of necessity exist even in the best-made doublet. It is however infinitely superior to a single lens, and will transmit a pencil of an angle of from 35° to 50° without any very sensible errors. It exhibits therefore many of the usual test-objects in a very beautiful manner.

The next step in the improvement of the simple microscope bears more analogy to the eye-piece. This improvement was made by Mr. Holland, and it consists (as shown in *fig. 6*) in substituting two lenses for the first in the doublet, and retaining the stop between them and the third. The first bending, being thus effected by two lenses instead of one, is accompanied by smaller aberrations, which are therefore more completely balanced or corrected at the second bend-

Fig. 6.

ing, in the opposite direction, by the third lens. This combination, though called a triplet, is essentially a doublet, in which the anterior lens is divided into two. For it must be recollected that the first pair of lenses merely accomplishes what might have been done, though with less precision, by one; but the two lenses of the doublet are opposed to each other; the second diminishing the magnifying power of the first. The first pair of lenses in the triplet concur in producing a certain amount of magnifying power, which is diminished in quantity and corrected as to aberration at the third lens by the change in relation to the position of the axis which takes place in the pencil between what is virtually the first and second lens. In this combination the errors are still further reduced by the close approximation to the object which causes the refractions to take place near the axis. Thus the transmission of a still larger angular pencil, namely 65° , is rendered compatible with distinctness, and a more intense image is presented to the eye.

Every increase in the number of lenses is attended with one drawback, from the circumstance that a certain portion of light is lost by reflection and absorption each time that the ray enters a new medium. This loss bears no sensible proportion to the gain arising from the increased aperture, which, being as the square of the diameter, multiplies rapidly; or if we estimate by the angle of the admitted pencil, which is more easily ascertained, the intensity will be as the square of twice the tangent of half the angle. To explain this, let DB (fig. 7) represent the diameter of the lens, or of that

part of it which is really employed; CA the perpendicular drawn from its centre, and AB, AD, the extreme rays of the incident pencil of light DAB. Then the diameter being $2CB$, the area to which the intensity of vision is proportional will be $(2CB)^2$, and CB is evidently the tangent of the angle CAB , which is half the angle of the admitted pencil DAB . Or, if a be used to denote the angular aperture, the expression for the intensity is $(2 \tan \frac{1}{2} a)^2$, which increases so rapidly

with the increase of a , as to make the loss of light by reflection and absorption of little consequence.

The combination of three lenses approaches, as has been stated, very close to the object; so close, indeed, as to prevent the use of more than three; and this constitutes a limit to the improvement of the simple microscope, for it is called a simple microscope, although consisting of three lenses, and although a compound microscope may be made of only three or even two lenses; but the different arrangement which gives rise to the term compound will be better understood when that instrument is explained.

Before we proceed to describe the simple microscope and its appendages, it will be well to explain such other points in reference to the form and materials of lenses as are most likely to be interesting.

A very useful form of lens was proposed by Dr. Wollaston, and called by him the Periscopic lens. It consisted of two hemispherical lenses, cemented together by their plane faces, having a stop between them to limit the aperture.

Fig. 8.

A similar proposal was made by Mr. Coddington, who however executed the project in a better manner, by cutting a groove in a whole sphere, and filling the groove with opaque matter. His lens, which is the well-known Coddington lens, is shown in fig. 8. It gives a large field of view, which is equally good in all directions, as it is evident that the pencils AA' and BB' pass through under precisely the same circumstances. Its spherical form has the further advantage of rendering the position in which it is held of comparatively little consequence. It is therefore very convenient as a hand-lens, but its definition is of course not so good as that of a well-made doublet or achromatic lens.

Another very useful form of doublet was proposed by Sir John Herschel, chiefly like the Coddington lens, for the sake of a wide field, and chiefly to be used in the hand. It is shown in fig. 9: it consists of a double convex or crossed lens, having the radii of curvature as 1 to 6, and of a

plane concave lens whose focal length is to that of the convex lens as 13 to 5.

Fig. 9.

Various, indeed innumerable, other forms and combinations of lenses have been projected, some displaying much ingenuity, but few of any practical use. In the Catadioptric lenses the light emerges at right angles from its entering direction, being reflected from a surface cut at an angle of 45° to the axes of the curved surfaces.

It was at one time hoped, as the precious stones are more refractive than glass, and as the increased refractive power is unaccompanied by a correspondent increase in chromatic dispersion, that they would furnish valuable materials for lenses, inasmuch as the refractions would be accomplished by shallower curves, and consequently with diminished spherical aberration. But these hopes were disappointed: everything that ingenuity and perseverance could accomplish was tried by Mr. Varley and Mr. Pritchard, under the patronage of Dr. Goring. It appeared however that the great reflective power, the doubly-refracting property, the colour, and the heterogeneous structure of the jewels which were tried, much more than counterbalanced the benefits arising from their greater refractive power, and left no doubt of the superiority of skilfully made glass doublets and triplets. The idea is now, in fact, abandoned; and the same remark is applicable to the attempts at constructing fluid lenses, and to the projects for giving to glass other than spherical surfaces,—none of which have come into extensive use.

By the term *simple microscope* is meant one in which the object is viewed directly through a lens or combination of lenses, just as we have supposed an arrow or an insect to be viewed through a glass held in the hand. When however the magnifying power of the glass is considerable, in other words, when its focal length is very short, and its proper distance from its object of consequence equally short, it requires to be placed at that proper distance with great precision: it cannot therefore be held with sufficient accuracy and steadiness by the unassisted hand, but must be mounted in a frame having a rack or screw to move it towards or from another frame or stage which holds the object. It is then called a microscope, and it is furnished, according to circumstances, with lenses and mirrors to collect and reflect the light upon the object, and with other conveniences which will now be described.

One of the best forms of a stand for a simple microscope is shown in fig. 10, where A is a brass pillar screwed to a

Fig. 10.

tripod base; B is a broad stage for the objects, secured to

the stem by screws, whose milled heads are at C. By means of the large milled head D, a triangular bar, having a rack, is elevated out of the stem A, carrying the lens-holder E, which has a horizontal movement in one direction, by means of a rack worked by the milled head F, and in the other direction by turning on a circular pin. A concave mirror G reflects the light upwards through the hole in the stage, and a lens may be attached to the stage for the purpose of throwing light on an opaque object, in the same way that the forceps H for holding such objects is attached. This microscope is peculiarly adapted, by its broad stage and its general steadiness, for dissecting; and it is rendered more convenient for this purpose by placing it between two inclined planes of mahogany, which support the arms and elevate the wrists to the level of the stage. This apparatus is called the dissecting rest. When dissecting is not a primary object, a joint may be made at the lower end of the stem A, to allow the whole to take an inclined position; and then the spring clips shown upon the stage are useful to retain the object in its place. Numerous convenient appendages may be made to accompany such microscopes, which it will be impossible to mention in detail: the most useful are Mr. Varley's capillary cages for containing animalculæ in water, and parts of aquatic plants; also his tubes for obtaining and separating such objects, and his phial and phial-holder for preserving and exhibiting small living specimens of the Chara, Nitella, and other similar plants, and observing their circulation. The phial-microscope affords facilities for observing the operations of minute vegetable and animal life, which will probably lead to the most interesting discoveries. The recent volumes of the Transactions of the Society of Arts contain an immense mass of information of this sort, and to these we refer the reader.

The mode of illuminating objects is one on which we must give some further information, for the manner in which an object is lighted is second in importance only to the excellence of the glass through which it is seen. In investigating any new or unknown specimen, it should be viewed in turns by every description of light, direct and oblique, as a transparent object and as an opaque object, with strong and with faint light, with large angular pencils and with small angular pencils thrown in all possible directions. Every change will probably develop some new fact in reference to the structure of the object, which should itself be varied in the mode of mounting in every possible way. It should be seen both wet and dry, and immersed in fluids of various qualities and densities, such as water, alcohol, oil, and Canada balsam, for instance, which last has a refractive power nearly equal to that of glass. If the object be delicate vegetable tissue, it will be in some respects rendered more visible by gentle heating or scorching by a clear fire placed between two plates of glass. In this way the spiral vessels of asparagus and other similar vegetables may be beautifully displayed. Dyeing the objects in tincture of iodine will in some cases answer this purpose better.

Fig. 11.

But the principal question in regard to illumination is the magnitude of the illuminating pencil, particularly in reference to transparent objects. Generally speaking the illuminating pencil should be as large as can be received by the lens, and no larger. Any light beyond this produces indistinctness and glare. The superfluous light from the mirror may be cut off by a screen having various-sized apertures placed below the stage; but the best mode of illumination is that proposed by Dr. Wollaston, and called the Wollaston condenser. A tube is placed below the stage of the instrument containing a lens A B (fig. 11), which can be elevated or depressed within certain limits at pleasure; and at the lower end is a stop with a limited aperture

CD. A plane mirror E F receives the rays of light L L from the sky or a white cloud, which last is the best source

of light, and reflects them upwards through the aperture in C D, so that they are refracted, and form an image of the aperture at G, which is supposed to be nearly the place of the object. The object is sometimes best seen when the image of the aperture is also best seen; and sometimes it is best to elevate the summit G of the cone A B G above the object, and at others to depress it below: all which is done at pleasure by the power of moving the lens A B. If artificial light (as a lamp or candle) be employed, the flame must be placed in the principal focus of a large detached lens on a stand, so that the rays L L may fall in parallel lines on the mirror, or as they would fall from the cloud. This will be found an advantage, not only when the Wollaston condenser is employed, but also when the mirror and diaphragm are used. A good mode of imitating artificially the light of a white cloud opposite the sun has been proposed by Mr. Varley: he covers the surface of the mirror under the stage with carbonate of soda or any similar material, and then concentrates the sun's light upon its surface by a large condensing lens. The intense white light diffused from the surface of the soda forms an excellent substitute for the white cloud, which, when opposite the sun and of considerable size, is the best day-light, as the pure sky opposite to the sun is the worst.

The Compound Microscope may, as before stated, consist of only two lenses, while a simple microscope has been shown to contain sometimes three. In the triplet for the simple microscope however it was explained that the effect of the two first lenses was to do what might have been accomplished, though not so well, by one; and the third merely effected certain modifications in the light before it entered the eye. But in the compound microscope the two lenses have totally different functions; the first receives the rays from the object, and, bringing them to new foci, forms an image, which the second lens treats as an original object, and magnifies it just as the single microscope magnified the object itself.

The annexed figure (12) shows the course of the rays through a compound microscope of two lenses. The rays proceeding from the object A B are so acted upon by the lens C D, near it, and thence called the object-glass, that they are converged to foci in A' B', where they form an enlarged image of the object, as would be evident if a piece of oiled paper or ground glass were placed there to receive them. They are not so intercepted, and therefore the image is not rendered visible at that place; but their further progress is similar to what it would have been had they really proceeded from an object at A' B'. They are at length received by the eye-lens L M, which acts upon them as the simple microscope has been described to act on the light proceeding from its objects. They are bent so that they may enter the eye at E in parallel lines, or as nearly so as is requisite for distinct vision. When we say that the rays enter the eye in nearly parallel lines, we mean only those which proceed from one point of the original object. Thus the two parallel rays M E have proceeded from and are part of the cone of rays C A D, emanating from the point A of the arrow; but they do not form two pictures in the eye, because any number of parallel rays which the pupil can receive will be converged to a point by the eye, and will convey the impression of one point to the mind. In like manner the rays L E are part of the cone of rays emanating from B, and the angle L E M is that under which the eye will see the magnified image of the arrow, which is evidently many times greater than the arrow could be made to occupy in the naked eye

Fig. 12.

at any distance within the limits of distinct vision. The magnifying power depends on two circumstances: first, on the ratio between the anterior distance AC or BD and the posterior focal length CB' or DA'; and secondly, on the power of the eye-lens LM. The first ratio is the same as that between the object AB and the image A'B'; this and the focal length or power of the eye-lens are both easily obtained, and their product is the power of the compound instrument.

Since the power depends on the ratio between the anterior and posterior foci of the object-glass, it is evident that by increasing that ratio any power may be obtained, the same eye-glass being used; or having determined the first, any further power may be obtained by increasing that of the eye-glass; and thus, by a pre-arrangement of the relative proportions in which the magnifying power shall be divided between the object-glass and the eye glass, almost any given distance (within certain limits) between the first and its object may be secured. This is one valuable peculiarity of the compound instrument; and another is the large field, or large angle of view, which may be obtained, every part of which will be nearly equally good; whereas with the best simple microscopes the field is small, and is good only in the centre. The field of the compound instrument is further increased by using two glasses at the eye-end; the first being called, from its purpose, the field-glass, and the two constituting what is called the eye-piece. This will be more particularly explained in the figure of the achromatic compound microscope presently given.

For upwards of a century the compound microscope, notwithstanding the advantages above mentioned, was a comparatively feeble and inefficient instrument, owing to the distance which the light had to traverse, and the consequent increase of the chromatic and spherical aberrations. To explain this we have drawn in *fig. 12* a second image near A'B', the fact being that the object-glass would not form one image, as has been supposed, but an infinite number of variously-coloured and various-sized images, occupying the space between the two dotted arrows. Those nearest the object-glass would be red, and those nearest the eye-glass would be blue. The effect of this is to produce so much confusion, that the instrument was reduced to a mere toy, although these errors were diminished to the utmost possible extent by limiting the aperture of the object-glass, and thus restricting the angle of the pencil of light from each point of the object. But this involved the defects, already explained, of making the picture obscure, so that on the whole the best compound instruments were inferior to the simple microscopes of a single lens, with which indeed all the important observations of the last century were made.

Even after the improvement of the simple microscope by the use of doublets and triplets, the long course of the rays and the large angular pencil required in the compound instrument deterred the most sanguine from anticipating the period when they should be conducted through such a path free both from spherical and chromatic errors. Within twenty years of the present period, philosophers of no less eminence than M. Biot and Dr. Wollaston predicted that the compound would never rival the simple microscope, and that the idea of achromatising its object-glass was hopeless. Nor can these opinions be wondered at when we consider how many years the achromatic telescope had existed without an attempt to apply its principles to the compound microscope. When we consider the smallness of the pencil required by the telescope, and the enormous increase of difficulty attending every enlargement of the pencil—when we consider further that these difficulties had to be contended with and removed by operations on portions of glass so small that they are themselves almost microscopic objects, we shall not be surprised that even a cautious philosopher and most able manipulator like Dr. Wollaston should prescribe limits to improvement.

Fortunately for science, and especially for the departments of animal and vegetable physiology, these predictions have been shown to be unfounded. The last fifteen years have sufficed to elevate the compound microscope from the condition we have described to that of being the most important instrument ever bestowed by art upon the investigator of nature. It now holds a very high rank among philosophical implements, while the transcendent beauties of form, colour, and organization which it reveals to us in the minute works of nature, render it subservient to the most delightful and instructive pursuits. To these claims on

our attention it appears likely to add a third of still higher importance. The microscopic examination of the blood and other human organic matter will in all probability afford more satisfactory and conclusive evidence regarding the nature and seat of disease than any hitherto appealed to, and will of consequence lead to similar certainty in the choice and application of remedies.

We have thought it necessary to state thus at large the claims of the modern achromatic microscope upon the attention of the reader, as a justification of the length at which we shall give its recent history and explain its construction; and we are further induced to this course by the consideration that the subject is entirely new ground, and that there are at this time not more than two or three makers of achromatic microscopes in England.

Soon after the year 1820 a series of experiments was begun in France by M. Selligues, which were followed up by Fraunhofer at Munich, by Amici at Modena, by M. Chevalier at Paris, and by the late Mr. Tulley in London. In 1824 the last-named excellent artist, without knowing what had been done on the Continent, made the attempt to construct an achromatic object-glass for a compound microscope, and produced one of nine-tenths of an inch focal length, composed of three lenses, and transmitting a pencil of eighteen degrees. This was the first that had been made in England; and it is due to Mr. Tulley to say, that as regards accurate correction throughout the field, that glass has not been excelled by any subsequent combination of three lenses. Such an angular pencil, and such a focal length, would bear an eye-piece adapted to produce a gross magnifying power of one hundred and twenty. Mr. Tulley afterwards made a combination to be placed in front of the first mentioned, which increased the angle of the transmitted pencil to thirty-eight degrees, and bore a power of three hundred.

While these practical investigations were in progress, the subject of achromatism engaged the attention of some of the most profound mathematicians in England. Sir John Herschel, Professor Airy, Professor Barlow, Mr. Codrington, and others, contributed largely to the theoretical examination of the subject; and though the results of their labours were not immediately applicable to the microscope, they essentially promoted its improvement.

For some time prior to 1829 the subject had occupied the mind of a gentleman, who, not entirely practical, like the first, nor purely mathematical, like the last-mentioned class of inquirers, was led to the discovery of certain properties in achromatic combinations which had been before unobserved. These were afterwards experimentally verified; and in the year 1829 a paper on the subject, by the discoverer, Mr. Joseph Jackson Lister, was read and published by the Royal Society. The principles and results thus obtained enabled Mr. Lister to form a combination of lenses which transmitted a pencil of fifty degrees, with a large field correct in every part: as this paper was the foundation of the recent improvements in achromatic microscopes, and as its results are indispensable to all who would make or understand the instrument, we shall give the more important parts of it in detail, and in Mr. Lister's own words.

'I would premise that the plano-concave form for the correcting flint lens has in that quality a strong recommendation, particularly as it obviates the danger of error which otherwise exists in centring the two curves, and thereby admits of correct workmanship for a shorter focus. To cement together also the two surfaces of the glass diminishes by very nearly half the loss of light from reflexion, which is considerable at the numerous surfaces of a combination. I have thought the clearness of the field and brightness of the picture evidently increased by doing this; it prevents any dewiness or vegetation from forming on the inner surfaces; and I see no disadvantage to be anticipated from it if they are of identical curves, and pressed closely together, and the cementing medium permanently homogeneous.

'These two conditions then, that the flint lens shall be plano-concave, and that it shall be joined by some cement to the convex, seem desirable to be taken as a basis for the microscopic object-glass, provided they can be reconciled with the destruction of the spherical and chromatic aberrations of a large pencil.

'Now in every such glass that has been tried by me which has had its correcting lens of either Swiss or English glass, with a double convex of plate, and has been made achromatic by the form given to the outer curve of the convex, the

proportion has been such between the refractive and dispersive powers of its lenses, that its figure has been correct for rays issuing from some point in its axis not far from its principal focus on its plane side, and either tending to a conjugate focus within the tube of a microscope, or emerging nearly parallel.

Fig. 13.

Let A B (fig. 13) be supposed such an object-glass, and let it be roughly considered as a plano-convex lens, with a curve ABC running through it, at which the spherical and chromatic errors are corrected which are generated at the two outer surfaces; and let the glass be thus free from aberration for rays FDEG issuing from the radiant point F, HE being a perpendicular to the convex surface, and ID to the plane one. Under these circumstances, the angle of emergence GEH much exceeds that of incidence FDI, being probably nearly three times as great.

If the radiant is now made to approach the glass, so that the course of the ray FDEG shall be more divergent from the axis, as the angles of incidence and emergence become more nearly equal to each other, the spherical aberration produced by the two will be found to bear a less proportion to the opposing error of the single correcting curve ACB; for such a focus therefore the rays will be over-corrected.

But if F still approaches the glass, the angle of incidence continues to increase with the increasing divergence of the ray, till it will exceed that of emergence, which has in the meanwhile been diminishing, and at length the spherical error produced by them will recover its original proportion to the opposite error of the curve of correction. When F has reached this point F'' (at which the angle of incidence does not exceed that of emergence so much as it had at first come short of it), the rays again pass the glass free from spherical aberration.

If F be carried from hence towards the glass, or outwards from its original place, the angle of incidence in the former case, or of emergence in the latter, becomes disproportionately effective, and either way the aberration exceeds the correction.

These facts have been established by careful experiment: they accord with every appearance in such combinations of the plano-convex glasses as have come under my notice, and may, I believe, be extended to this rule, that in general an achromatic object-glass, of which the inner surfaces are in contact, or nearly so, will have on one side of it two foci in its axis, for the rays proceeding from which it will be truly corrected at a moderate aperture; that for the space between these two points its spherical aberration will be over-corrected, and beyond them either way under-corrected.

The longer aplanatic focus may be found, when one of the plano-convex object-glasses is placed in a microscope, by shortening the tube, if the glass shows over-correction; if under-correction, by lengthening it, or by bringing the rays together, should they be parallel or divergent, by a very small good telescope. The shorter focus is got at by sliding the glass before another of sufficient length and large aperture that is finely corrected, and bringing it forwards till it gives the reflexion of a bright point from a globule of quicksilver, sharp and free from mist, when the distance can be taken between the glass and the object.

The longer focus is the place at which to ascertain the utmost aperture that may be given to the glass, and where, in the absence of spherical error, its exact state of correction as to colour is seen most distinctly.

The correction of the chromatic aberration, like that of the spherical, tends to excess in the marginal rays; so that if a glass which is achromatic, with a moderate aperture, has its cell opened wider, the circle of rays thus added to the pencil will be rather over-corrected as to colour.

The same tendency to over-correction is produced, if, without varying the aperture, the divergence of the incident rays is much augmented, as in an object-glass placed in front of another; but generally in this position a part only of its aperture comes into use; so that the two properties

mentioned neutralize each other, and its chromatic state remains unaltered. If for example the outstanding colours were observed at the longer focus to be green and claret, which show that the nearest practicable approach is made to the union of the spectrum, they usually continue nearly the same for the whole space between the foci, and for some distance beyond them either way.

The places of these two foci and their proportions to each other depend on a variety of circumstances. In several object-glasses that I have had made for trial, plano-convex, with their inner surfaces cemented, their diameters the radius of the flint lens, and their colour pretty well corrected, those composed of dense flint and light plate have had the rays from the longer focus emerging nearly parallel; and this focus has been not quite three times the distance of the shorter from the glass: with English flint the rays have had more convergence, and the shorter focus has borne a rather less proportion to the longer.

If the surfaces are not cemented, a striking effect is produced by minute differences in their curves. It may give some idea of this, that in a glass of which nearly the whole disk was covered with colour from contact of the lenses, the addition of a film of varnish, so thin that this colour was not destroyed by it, caused a sensible change in the spherical correction.

I have found that whatever extended the longer aplanatic focus, and increased the convergence of its rays, diminished the relative length of the shorter. Thus by turning to the concave lens the flatter instead of the deeper side of a convex lens, whose radii were to each other as 31 to 35, the pencil of the longer aplanatic focus, from being greatly divergent, was brought to converge at a very small distance behind the glass; and the length of the shorter focus, which had been one-half that of the longer, became but one-sixth of it.

The direction of the aplanatic pencils appears to be scarcely affected by the differences in the thickness of glasses, if their state as to colour is the same.

One other property of the double object-glass remains to be mentioned, which is, that when the longer aplanatic focus is used, the marginal rays of a pencil not coincident with the axis of the glass are distorted, so that a coma is thrown outwards; while the contrary effect of a coma directed towards the centre of the field is produced by the rays from the shorter focus. These peculiarities of the coma seem inseparable attendants on the two foci, and are as conspicuous in the achromatic meniscus as in the plano-convex object-glass.

Of several purposes to which the particulars just given seem applicable, I must at present confine myself to the most obvious one. They furnish the means of destroying with the utmost ease both aberrations in a large focal pencil, and of thus surmounting what has hitherto been the chief obstacle to the perfection of the microscope. And when it is considered that the curves of its diminutive object-glasses have required to be at least as exactly proportioned as those of a large telescope to give the image of a bright point equally sharp and colourless, and that any change made to correct one aberration was liable to disturb the other, some idea may be formed of what the amount of that obstacle must have been. It will however be evident that if any object-glass is but made achromatic, with its lenses truly worked and cemented, so that their axes coincide, it may with certainty be connected with another possessing the same requisites and of suitable focus, so that the combination shall be free from spherical error also in the centre of its field. For this the rays have only to be received by the front glass B (fig. 14) from its shorter aplanatic focus F'', and transmitted in the direction of the longer correct pencil FA of the other glass A. It is desirable that the latter pencil should neither converge to a very short focus nor be more than very slightly if at all divergent; and a little attention at first to the kind of glass used will keep it within this range, the denser flint being suited to the glasses of shorter focus and larger angle of aperture.

Fig. 14.

'The adjustment of the microscope is then perfected, if necessary, by slightly varying the distance between the object-glasses; and after that is done, the length of the tube which carries the eye-pieces may be altered greatly without disturbing the correction, opposite errors which balance each other being produced by the change.

'If the two glasses which in the diagram are drawn at some distance apart are brought nearer together (if the place of A for instance is carried to the dotted figure), the rays transmitted by B in the direction of the longer aplanatic pencil of A will plainly be derived from some point Z more distant than F'', and lying between the aplanatic foci of B; therefore (according to what has been stated) this glass, and consequently the combination, will then be spherically over-corrected. If on the other hand the distance between A and B is increased, the opposite effects are of course produced.

'In combining several glasses together it is often convenient to transmit an under-corrected pencil from the front glass, and to counteract its error by over-correction in the middle one.

'Slight errors in colour may in the same manner be destroyed by opposite ones; and on the principles described we not only acquire fine correction for the central ray, but, by the opposite effects at the two foci on the transverse pencil, all coma can be destroyed, and the whole field rendered beautifully flat and distinct.'

Mr. Lister's paper enters into further particulars, which are not essential to the comprehension of the subject. It is sufficient to say that his investigations and results proved to be of the highest value to the practical optician, and the progress of improvement was in consequence extremely rapid. The new principles were applied and exhibited by Mr. Hugh Powell and Mr. Andrew Ross with a degree of success which had never been anticipated; so perfect indeed were the corrections given to the achromatic object-glass—so completely were the errors of sphericity and dispersion balanced or destroyed—that the circumstance of covering the object with a plate of the thinnest glass or tale disturbed the corrections, if they had been adapted to an uncovered object, and rendered an object-glass which was perfect under one condition sensibly defective under the other.

This defect, if that should be called a defect which arose out of improvement, was first discovered by Mr. Ross, who immediately suggested the means of correcting it, and presented to the Society of Arts, in 1837, a paper on the subject, which was published in the 51st volume of their Transactions, and which, as it is, like Mr. Lister's, essential to a full understanding of the ultimate refinements of the instrument, we shall extract nearly in full.

'In the course of a practical investigation (says Mr. Ross) with the view of constructing a combination of lenses for the object-glass of a compound microscope, which should be free from the effects of aberration, both for central and oblique pencils of great angle, I combined the condition of the greatest possible distance between the object and object-glass; for in object-glasses of short focal length their closeness to the object has been an obstacle in many cases to the use of high magnifying powers, and is a constant source of inconvenience.

'In the improved combination, the diameter is only sufficient to admit the proper pencil; the convex lenses are wrought to an edge, and the concave have only sufficient thickness to support their figure; consequently, the combination is the thinnest possible, and it follows that there will be the greatest distance between the object and the object-glass. The focal length is $\frac{1}{2}$ of an inch, having an angular aperture of 60° , with a distance of $\frac{1}{25}$ of an inch, and a magnifying power of 970 times linear with perfect definition on the most difficult Podura scales. I have made object-glasses $\frac{1}{2}$ of an inch focal length; but as the angular aperture cannot be advantageously increased, if the greatest distance between the object and object-glass is preserved, their use will be very limited.

'The quality of the definition produced by an achromatic compound microscope will depend upon the accuracy with which the aberrations, both chromatic and spherical, are balanced, together with the general perfection of the workmanship. Now, in Wollaston's doublets, and Holland's triplets, there are no means of producing a balance of the aberrations, as they are composed of convex lenses only; therefore the best that can be done is to make the aberrations a minimum: the remaining positive aberration in

these forms produces its peculiar effect upon objects (particularly the detail of the thin transparent class), which may lead to misapprehension of their true structure; but with the achromatic object-glass, where the aberrations are correctly balanced, the most minute parts of an object are accurately displayed, so that a satisfactory judgment of their character may be formed.

'It will be seen by fig. 15, that when a certain angular pencil A O A' proceeds from the object O, and is incident on the plane side of the first lens, if the combination is removed from the object, as in fig. 16, the extreme rays of the pencil impinge on the more marginal parts of the glass, and as the refractions are greater here, the aberrations will be greater also. Now, if two compound object-glasses have their aberrations balanced, one being situated as in fig. 15, and the other as in fig. 16, and the same disturbing power applied to both, that in which the angles of incidence and the aberrations are small will not be so much disturbed as where the angles are great, and where consequently the aberrations increase rapidly.

'When an object-glass has its aberrations balanced for viewing an opaque object, and it is required to examine that object by transmitted light, the correction will remain; but if it is necessary to immerse the object in a fluid, or to cover it with glass or tale, an aberration will arise from these circumstances, which will disturb the previous correction, and consequently deteriorate the definition; and this effect will be more obvious with the increase of the distance between the object and the object-glass.

'The aberration produced with diverging rays by a piece of flat and parallel glass, such as would be used for covering an object, is represented at fig. 17, where G G G G is the refracting medium, or piece of glass covering the object O; O P, the axis of the pencil, perpendicular to the flat surfaces; O T, a ray near the axis; and O T', the extreme ray of the pencil incident on the under surface of the glass: then T R, T' R', will be the directions of the rays in the medium, and R E, R' E', those of the emergent rays. Now if the course of these rays is continued, as by the dotted lines, they will be found to intersect the axis at different distances, X and Y, from the surface of the glass; and the distance X Y is the aberration produced by the medium which, as before stated, interferes with the previously balanced aberrations of the several lenses composing the object-glass. There are many cases of this, but the one here selected serves best to illustrate the principle, I need

not encumber the description with the theoretical determination of this quantity, as it varies with exceedingly minute circumstances which we cannot accurately control; such as the distance of the object from the under side of the glass, and the slightest difference in the thickness of the glass itself; and if these data could be readily obtained, the knowledge would be of no utility in making the correction, that being wholly of a practical nature.

'If an object-glass is constructed as represented in *fig. 16*, where the posterior combination P and the middle M have together an excess of negative aberration, and if this be corrected by the anterior combination A, having an excess of positive aberration, then this latter combination can be made to act more or less powerfully upon P and M, by making it approach to or recede from them; for when the three are in close contact, the distance of the object from the object-glass is greatest; and consequently the rays from the object are diverging from a point at a greater distance than when the combinations are separated; and as a lens bends the rays more, or acts with greater effect, the more distant the object is from which the rays diverge, the effect of the anterior combination A upon the other two, P and M, will vary with its distance from thence. When therefore the correction of the whole is effected for an opaque object with a certain distance between the anterior and middle combination, if they are then put in contact, the distance between the object and object-glass will be increased; consequently the anterior combination will act more powerfully, and the whole will have an excess of positive aberration. Now the effect of the aberration produced by a piece of flat and parallel glass being of the negative character, it is obvious that the above considerations suggest the means of correction by moving the lenses nearer together, till the positive aberration thereby produced balances the negative aberration caused by the medium.

'The preceding refers only to the spherical aberration, but the effect of the chromatic is also seen when an object is covered with a piece of glass; for, in the course of my experiments, I observed that it produced a chromatic thickening of the outline of the Podura and other delicate scales; and if diverging rays near the axis and at the margin are projected through a piece of flat parallel glass, with the various indices of refraction for the different colours, it will be seen that each ray will emerge separated into a beam consisting of the component colours of the ray, and that each beam is widely different in form. This difference, being magnified by the power of the microscope, readily accounts for the chromatic thickening of the outline just mentioned. Therefore to obtain the finest definition of extremely delicate and minute objects, they should be viewed without a covering; if it be desirable to immerse them in a fluid, they should be covered with the thinnest possible film of tale, as, from the character of the chromatic aberration, it will be seen that varying the distances of the combinations will not sensibly affect the correction; though object-lenses may be made to include a given fluid or solid medium in their correction for colour.

'The mechanism for applying these principles to the correction of an object-glass under the various circumstances, is represented in *fig. 18*, where the anterior lens is set in the

Fig. 18.

end of a tube A A, which slides on the cylinder B containing the remainder of the combination; the tube A A, holding the lens nearest the object, may then be moved upon the cylinder B, for the purpose of varying the distance according to the thickness of the glass covering the object, by turning the screwed ring C C, or more simply by sliding the one on the other, and clamping them together when adjusted. An aperture is made in the tube A, within which is seen a mark engraved on the cylinder, and on the edge of which are two marks, a longer and a shorter, engraved upon the tube. When the mark on the cylinder coincides with the longer mark on the tube, the adjustment is perfect for an uncovered object; and when the coincidence is with the short mark, the proper distance is obtained to balance the aberrations produced by glass $\frac{1}{100}$ th of an inch thick, and such glass can be readily supplied.

'It is hardly necessary to observe, that the necessity for this correction is wholly independent of any particular construction of the object-glass; as in all cases where the object-glass is corrected for an object uncovered, any covering of glass will create a different value of aberration to the first lens, which previously balanced the aberration resulting from the rest of the lenses; and, as this disturbance is effected at the first refraction, it is independent of the other part of the combination. The visibility of the effect depends on the distance of the object from the object-glass, the angle of the pencil transmitted, the focal length of the combination, the thickness of the glass covering the object, and the general perfection of the corrections for chromatism and the oblique pencils.

'With this adjusting object-glass, therefore, we can have the requisites of the greatest possible distance between the object and object-glass, an intense and sharply defined image throughout the field from the large pencil transmitted, and the accurate correction of the aberrations; also, by the adjustment, the means of preserving that correction under all the varied circumstances in which it may be necessary to place an object for the purpose of observation.'

In the annexed engraving, *fig. 19*, we have shown the triple achromatic object-glass in connection with the eye-piece consisting of the field-glass F F and the eye-glass E E, forming together the modern achromatic microscope. The course of the light is shown by drawing three rays from the centre and three from each end of the object O. These rays would, if left to themselves, form an image of the object at A A, but being bent and converged by the field-glass F F, they form the image at B B, where a stop is placed to intercept all light except what is required for the formation of the image. From B B therefore the rays proceed to the eye-glass exactly as has been described in reference to the simple microscope and to the compound of two glasses.

If we stopped here we should convey a very imperfect idea of the beautiful series of corrections effected by the eye-piece, and which were first pointed out in detail in a paper on the subject published by Mr. Varley in the 51st volume of the Transactions of the Society of Arts. The eye-piece in question was invented by Huyghens for telescopes, with no other view than

that of diminishing the spherical aberration by producing the refractions at two glasses instead of one, and of increasing the field of view. It was reserved for Boscovich to

Fig. 19.

point out that Huyghens had by this arrangement accidentally corrected a great part of the chromatic aberration, and this subject is further investigated with much skill in two papers by Professor Airy in the *Cambridge Philosophical Transactions*, to which we refer the mathematical reader. These investigations apply chiefly to the telescope, where the small pencils of light and great distance of the object exclude considerations which become important in the microscope, and which are well pointed out in Mr. Varley's paper before mentioned.

Fig. 20.

Let *fig. 20* represent the Huyghenian eye-piece of a microscope; *FF* and *EE* being the field-glass and eye-glass, and *LMN* the two extreme rays of each of the three pencils, emanating from the centre and ends of the object, of which, but for the field-glass, a series of coloured images would be formed from *RR* to *BB*; those near *RR* being red, those near *BB* blue, and the intermediate ones green, yellow, and so on, corresponding with the colours of the prismatic spectrum. This order of colours, it will be observed, is the reverse of that described in treating of the common compound microscope (*fig. 12*), in which the single object-glass projected the red image beyond the blue. The effect just described, of projecting the blue image beyond the red, is purposely produced for reasons presently to be given, and is called over-correcting the object-glass as to colour. It is to be observed also that the images *BB* and *RR* are curved in the wrong direction to be distinctly seen by a convex eye-lens, and this is a further defect of the compound microscope of two lenses. But the field-glass, at the same time that it bends the rays and converges them to foci at *B'B'* and *R'R'*, also reverses the curvature of the images as there shown, and gives them the form best adapted for distinct vision by the eye-glass *EE*. The field-glass has at the same time brought the blue and red images closer together, so that they are adapted to pass uncoloured through the eye-glass. To render this important point more intelligible, let it be supposed that the object-glass had not been over-corrected, that it had been perfectly achromatic; the rays would then have become coloured as soon as they had passed the field-glass; the blue rays, to take the central pencil for example, would converge at *b* and the red rays at *r*, which is just the reverse of what the eye-lens requires; for as its blue focus is also shorter than its red, it would demand rather that the blue image should be at *r* and the red at *b*. This effect we have shown to be produced by the over-correction of the object-glass, which protrudes the blue foci *BB* as much beyond the red foci *RR* as the sum of the distances between the red and blue foci of the field-lens and eye-lens; so that the separation *BR* is exactly taken up in passing through those two lenses, and the whole of the colours coincide as to focal distance as soon as the rays have passed the eye-lens. But while they coincide as to distance, they differ in another respect; the blue images are rendered smaller than the red by the superior refractive power of the

field-glass upon the blue rays. In tracing the pencil *L* for instance, it will be noticed that after passing the field-glass, two sets of lines are drawn, one whole, and one dotted, the former representing the red, and the latter the blue rays. This is the accidental effect in the Huyghenian eye-piece pointed out by Boscovich. This separation into colours at the field-glass is like the over-correction of the object-glass; it leads to a subsequent complete correction. For if the differently coloured rays were kept together till they reached the eye-glass, they would then become coloured, and present coloured images to the eye; but fortunately, and most beautifully, the separation effected by the field-glass causes the blue rays to fall so much nearer the centre of the eye-glass, where, owing to the spherical figure, the refractive power is less than at the margin, that the spherical error of the eye-lens constitutes a nearly perfect balance to the chromatic dispersion of the field-lens, and the red and blue rays *L'* and *L''* emerge sensibly parallel, presenting, in consequence, the perfect definition of a single point to the eye. The same reasoning is true of the intermediate colours and of the other pencils.

From what has been stated it is obvious that we mean by an achromatic object-glass one in which the usual order of dispersion is so far reversed, that the light, after undergoing the singularly beautiful series of changes effected by the eye-piece, shall come uncoloured to the eye. We can give no specific rules for producing these results. Close study of the formulæ for achromatism given by the celebrated mathematicians we have quoted will do much, but the principles must be brought to the test of repeated experiment. Nor will the experiments be worth anything, unless the curves be most accurately measured and worked, and the lenses centred and adjusted with a degree of precision which, to those who are familiar only with telescopes, will be quite unprecedented.

The Huyghenian eye-piece which we have described is the best for merely optical purposes, but when it is required to measure the magnified image, we use the eye-piece invented by Mr. Ramsden, and called, from its purpose, the micrometer eye-piece. When it is stated that we sometimes require to measure portions of animal or vegetable matter a hundred times smaller than any divisions that can be artificially made on any measuring instrument, the advantage of applying the scale to the magnified image will be obvious, as compared with the application of engraved or mechanical micrometers to the stage of the instrument.

Fig. 21.

The arrangement is shown in *fig. 21*, where *EE* and *FF* are the eye and field glass, the latter having now its plane face towards the object. The rays from the object are here made to converge at *AA*, immediately in front of the field-glass, and here also is placed a plane glass on which are engraved divisions of $\frac{1}{100}$ th of an inch or less. The markings of these divisions come into focus therefore at the same time as the image of the object, and both are distinctly seen together. Thus the measure of the magnified image is given by mere inspection, and the value of such measures in reference to the real object may be obtained thus, which, when once obtained, is constant for the same object-glass. Place on the stage of the instrument a divided scale the value of which is known, and viewing this scale as the microscopic object, observe how many of the divisions on the scale attached to the eye-piece correspond with one of those in the magnified image. If, for instance, ten of those in the eye-piece correspond with one of those in the image, and if the divisions are known to be equal, then the image is ten times larger than the object, and the dimensions of the object are ten times less than indicated by the micrometer. If the divisions on the micrometer and on the magnified scale were not equal, it becomes a mere rule-of-three sum, but in general this trouble is

taken by the maker of the instrument, who furnishes a table showing the value of each division of the micrometer for every object-glass with which it may be used.

While on the subject of measuring it may be well to explain the mode of ascertaining the magnifying power of the compound microscope, which is generally taken on the assumption before mentioned, that the naked eye sees most distinctly at the distance of ten inches.

Place on the stage of the instrument, as before, a known divided scale, and when it is distinctly seen, hold a rule at ten inches distance from the disengaged eye, so that it may be seen by that eye, overlapping or lying by side of the magnified picture of the other scale. Then move the rule till one or more of its known divisions correspond with a number of those in the magnified scale, and a comparison of the two gives the magnifying power.

Having now explained the optical principles of the achromatic compound microscope, it remains only to describe the mechanical arrangements for giving those principles their full effect. The mechanism of a microscope is of much more importance than might be imagined by those who have not studied the subject. In the first place, steadiness, or freedom from vibration, and most particularly freedom from any vibrations which are not equally communicated to the object under examination, and to the lenses by which it is viewed, is a point of the utmost consequence. When, for instance, the body containing the lenses is screwed by its lower extremity to a horizontal arm, we have one of the most vibratory forms conceivable; it is precisely the form of the inverted pendulum, which is expressly contrived to indicate otherwise insensible vibrations. The tremor necessarily attendant on such an arrangement is magnified by the whole power of the instrument; and as the object on the stage partakes of this tremor in a comparatively insensible degree, the image is seen to oscillate so rapidly, as in some cases to be wholly undistinguishable. Such microscopes cannot possibly be used with high powers in ordinary houses abutting on any paved streets through which carriages are passing, nor indeed are they adapted to be used in houses in which the ordinary internal sources of shaking exist.

One of the best modes of mounting a compound microscope is shown in the annexed view (*fig. 22*), which, though too minute to exhibit all the details, will serve to explain the chief features of the arrangement.

A massy pillar *A* is screwed into a solid tripod *B*, and is surmounted by a strong joint at *C*, on which the whole instrument turns, so as to enable it to take a perfectly horizontal or vertical position, or any intermediate angle, such, for instance, as that shown in the engraving.

This moveable portion of the instrument consists of one solid casting *D E F G*; from *F* to *G* being a thick pierced plate carrying the stage and its appendages. The compound body *H* is attached to the bar *D E*, and moves up and down upon it by a rack and pinion worked by either of the milled heads *K*. The piece *D E F G* is attached to the pillar by the joint *C*, which being the source of the required movement in the instrument, is obviously its weakest part, and about which no doubt considerable vibration takes place. But inasmuch as the piece *D E F G* of necessity transmits such vibrations equally to the body of the microscope and to the objects on the stage, they hold always the same relative position, and no *visible* vibration is caused, how much soever may really exist. To the under side of the stage is attached a circular stem *L*, on which slides the mirror *M*, plane on one side and concave on the other, to reflect the light through the aperture in the stage. Beneath the stage is a circular revolving plate containing three apertures of various sizes, to limit the angle of the pencil of light which shall be allowed to fall on the object under examination. Besides these conveniences the stage has a double movement produced by two racks at right angles to each other, and worked by milled heads beneath. It has also the usual appendages of forceps to hold minute objects, and a lens to condense the light upon them, all of which are well understood, and if not, will be rendered more intelligible by a few minutes' examination of a microscope than by the most lengthened description. One other point remains to be noticed. The movement produced by the milled head *K* is not sufficiently delicate to adjust the focus of very powerful lenses, nor indeed is any rack movement. Only the finest screws are adapted to this purpose; and even these are improved by means for reducing the rapidity of the

Fig. 22.

screw's movement. For this purpose the lower end of the compound body *H*, which carries the object-glass, consists of a piece of smaller tube sliding in parallel guides in the main body, and kept constantly pressed upwards by a spiral spring, but it can be drawn downward by a lever crossing the body, and acted on by an extremely fine screw whose milled head is seen at *N*, and the fineness of which is tripled by means of the lever through which it acts on the object-glass. The instrument is of course roughly adjusted by the rack movement, and finished by the screw, or by such other means as are chosen for the purpose. One very ingenious contrivance, but applied to the stage instead of the body of the microscope, invented by Mr. Powell, will be found described in the 50th volume of the Transactions of the Society of Arts.

The greater part of the directions for viewing and illuminating objects given in reference to the simple microscope are applicable to the compound. An argand lamp placed in the focus of a large detached lens so as to throw parallel rays upon the mirror, is the best artificial light; and for opaque objects the light so thrown up may be reflected by metallic specula (called, from their inventor, Lieberkühns) attached to the object-glasses.

It has been recently proposed by Sir David Brewster and by M. Dujardin to render the Wollaston condenser achromatic, and they have accordingly been made with three pairs of achromatic lenses instead of the single lens before described, with very excellent effect. The last mentioned gentleman has also projected an ingenious apparatus, called the Hyptioscope, attached to the eye-piece for the purpose of erecting the magnified picture.

The erector commonly applied to the compound microscope consists of a pair of lenses acting like the erecting eye-piece of the telescope. But this, though it is convenient for the purpose of dissection, very much impairs the optical performance of the instrument.

For drawing the images presented by the microscope the best apparatus consists of a mirror *M* (*fig. 23*), composed of a thin piece of rather dark-coloured glass cemented on to

a piece of plate-glass inclined at an angle of 45° in front of the eye-glass *E*. The light escaping from the eye-glass is assisted in its reflection upwards to the eye by the dark glass, which effects the further useful purpose of rendering the paper less brilliant, and thus enabling the eye better to see the reflected image. The lens *L* below the reflector is to cause the light from the paper and pencil to diverge from the same distance as that received from the eye-glass; in other words, to cause it to reach the eye in parallel lines.

Fig. 23.

Dr. Wollaston's Camera Lucida, as shown in *fig. 24*, is sometimes attached to the eye-piece of the microscope for the same purpose. In this instrument the rays suffer two internal reflexions within the glass prism, as will be seen explained in the article CAMERA LUCIDA. In this minute figure we have omitted to trace the reflected rays, merely to avoid confusion.

Fig. 24.

Annexed are four engravings of microscopic objects, the true character of which it is however impossible to give in wood, and is difficult indeed to accomplish by any description of engraving.

Fig. 25.

Fig. 26.

Fig. 27.

Fig. 25 shows a scale of the small insect called Podura Plumbea, the common Skiptail, magnified about five hundred times. To define the markings on this scale clearly is the highest test of a deep achromatic object-glass; and this drawing is given rather to explain what the observer should look for, than as a very correct representation. *Fig. 26* is

Fig. 28.

a scale or feather of the Menelaus Butterfly; *Fig. 27* is the hair of a singular insect, the Dermestes; and *Fig. 28* is a longitudinal cutting of fir, showing the circular glands on the vessels which distinguish coniferous woods. These latter objects may be seen by half-inch or quarter-inch achromatic glasses. Opaque objects are generally better exhibited by inch and two-inch glasses when a general view of them is required, and by higher powers when we wish to examine their minute structure. In the latter case the light must be obtained by condensing lenses instead of the metallic specula.

Although the reflecting microscope is now very little used, it may be expected that we should mention it. In this instrument, at *Fig. 29*,

Fig. 29.

the object *O* is reflected by the inclined face of the mirror *M*, and the rays are again reflected and converged by the ellipsoidal reflector *RR*, which effects the same purpose as the object-glass of the compound microscope. It forms

an image which is not susceptible of the over-correction as to colour before described, and which therefore becomes coloured in passing through the eye-piece. This fact, and the loss of light by reflection, will probably always render the reflecting microscope inferior to the achromatic refracting.

The solar microscope has been so nearly superseded by the oxy-hydrogen, that a brief description of the latter must suffice, particularly as their optical principles are similar.

The primary object in both is to throw an intense light upon the object, which is sometimes done by mirrors, and sometimes by lenses. In *fig. 30*, *L* represents the cylinder

Fig. 30.

of burning lime, *RR* the reflector, which concentrates the light upon the object *OO*; the rays from which, passing through the two plano-convex lenses, are brought to foci upon a screen placed at a great distance, and upon which is formed the magnified image.

Fig. 31 shows a combination of lenses to condense the light upon the object.

Fig. 31.

In either case the optical arrangements by which the image is formed admit of the same perfection as those which have been described for the compound microscopes. A few achromatic glasses for oxy-hydrogen mi-

croscopes have been made, and they will ultimately become valuable instruments for illustrating lectures on natural history and physiology. One made by Mr. Ross was exhibited a few months since at the Society of Arts to illustrate a lecture on the physiology of woods. It should be observed however that the oxy-hydrogen or solar microscope requires either a spherical screen, or that the objects should be mounted between spherical glasses, in order to bring the whole into focus at one time. This latter plan was adopted on the occasion just mentioned with perfect success.

MICROSCOPIUM (the Microscope), a constellation of Lacaille, situated above Grus and Indus at the junction of Capricornus and Sagittarius. The only star in it worth notice is α , of the $4\frac{1}{2}$ magnitude, (307) in the catalogue of Piazzi, and 2454 in that of the Astronomical Society.

MICROTUS, Schrank's name for a genus of Murino Rodents, embracing our English Water-rat, *Mus amphibius*, Linn., &c. [MURIDÆ.]

MICROZOA'RIA (literally, 'little animals'). This is the title employed by M. de Blainville for the Animalcula infusoria of earlier writers, who commonly classed these singular objects of microscopic research among the Zoophyta. Baker, Needham, Buffon, and Spallanzani, occupied with the singular facts and hypotheses regarding the origin and vitality of these animated points, gave little attention to their zoological relations; the works of Linnæus contain almost no notice of more than the larger Vorticellæ, Brachioni, and Volvoces, which are ranked among the Vermes Zoophyta. The great founder of all the classifications of the minute Infusoria, the first careful observer of their permanent

characters of form, surface, movements, and internal structure, is the accurate O. F. Müller, author of the 'Zoologia Danica.' Considering that in 1786 (the date of his work) the microscope had been scarcely at all improved since the days of Hooke, the numerous figures which Müller presented were highly creditable to his eye and hand. They have been frequently copied (as in the 'Encyclopédie Méthodique'), and yet retain a high value.

Müller's classification, founded upon the figure and surface of the animal, is convenient to the observer who desires to name the active molecules which pass under his microscope, but unsatisfactory to the zoological student.

The genera are arranged in some degree according to their apparent simplicity.

A. Without external organs.

* Substance thick.

Monas. A mere point.

Proteus. Of variable figure.

Volvox. Spherical.

Enchelis. Cylindrical.

Vibrio. Round, elongated. (Several of the animals included in this group should have been ranked among the Vermes.)

* Membranaceous.

Cyclidium. Oval, complanate (generate by division).

Paramecium. Of an oblong figure (generate by division).

Kolpoda. Sinuate, complanate (generate by division).

Gonium. An angular mass.

Bursaria. Hollow like a purse.

B. With external organs.

* Naked.

Cercaria. With an extension like a tail. Some are said to have eyes.

Trichoda. Named for its hairiness (generate by division).

Kerona. With little horny protuberances.

Himantopus. With slender extensions or cirri.

Leucophra. Ciliated over all the surface (generate by division).

Vorticella. Ciliated about the mouth, contractile. The ciliæ have a whirling motion.

** Covered with a shell.

Brachionus. Ciliated nearly as *Vorticella*.

On this classification Lamarck (*Anim. sans Vertébrés*) has made few alterations; he preserves the same genera nearly in the same order in all the naked Infusoria, but rejects from those with external organs (Infusores appendiculés) *Vorticella* and *Brachionus* (which he places among his Polypi), and re-arranges the others thus:

Infusores appendiculés.

No tail { *Trichoda* (including *Leucophra* of Müller).
 Kerona (including *Himantopus* of Müller).

A tail { *Cercaria*.
 Furcocercaria.

The remaining groups are thus classed among the Polypi:

Polypi ciliati.

Section I. Vibratiles with oral ciliæ, having vibratory movement.

Rattulus. (*Trichoda rattus* and *T. clavus* of Müller.)

Trichocerca. (*Cercaria forcipata*, &c., Müller.)

Vaginicola. *Trichoda inquilina*, &c., Müller.)

Section II. Rotiferæ, with oval ciliæ having rotatory movement.

Folliculina. (*Vorticella ampulla*, *vaginata*, &c., Müller.)

Brachionus. (Divided into sections, with or without a tail.)

Furcularia. (Includes the *Vorticella rotatoria*, or wheel-animal and others allied to it.)

Urceolaria. (*Vorticella viridis*, *bursaria*, &c., Müller.)

Vorticella. (The pedunculated species of Müller, both simple and compound.)

Tubicolaria.

Cuvier constitutes for the Infusoria his fifth and last class of zoophyta, observing however, what always struck the least informed zoologist, who contemplated the various forms and habits of these animals, that among them were several grades of organization, and some forms which could not be reconciled to zoophytic structure. Bory de St. Vincent had adopted (*Encyclop. Méthod.*, 1826) eighty-two genera, but Cuvier even reduces the number of Lamarckian genera.

Blainville (*Actinologie*, p. 162) gives the following arrangement of the Microzoaria.

Division I. Microzoaria Heteropoda.

Section 1. Rotiferæ. Body distinguished in parts anterior, medial, posterior (sometimes really showing head, thorax, abdomen), with anterior bundles of ciliæ, which in their rapid movement resemble wheels. Posterior appendices simple, terminal.

The genera are as in Lamarck, with indications of the subgenera adopted by Bory de St. Vincent.

Section 2. Ciliifera, with lateral ciliiform appendices. The genera are taken from Müller, viz. *Kerona*, *Himantopus*, *Paramœcium*, *Trichoda*, *Leucophra*, *Volvox*, *Cyclidium*, *Monas*, with indications of the subdivisions adopted by Bory de St. Vincent, &c.

Division II. Microzoaria apoda, with no external appendices, including *Bursaria*, *Kolpoda*, *Trachelina* (*Vibrio*, Müller), *Proteus*, *Cercaria*, *Enchelis*, *Gonium*. Many of these are thought by Blainville to be young Planariæ or Hirudines.

Nearly all the real information which accompanied these slight transformations of Müller's system of classification was derived from the numerous and acute observations of that eminent naturalist, whose figures and descriptions we have often compared with the indications of the microscope before this instrument received the marvellous improvements of Amici, Chevalier, Pritchard, Plösl, and Schiek. By their inventions, and the able use made of them since 1828, a new mine of knowledge has been opened on the history, structure, and zoological relations of the Infusoria. Professor Ehrenberg of Berlin has been highly successful in detecting unexpected points of structure even in the minutest animalculæ, and has in consequence proposed a new and remarkable classification, depending on a great variety of organizations, which he has discovered and already in a considerable degree made known. (*Organization der Infusionstierchen*, Berlin, 1830; *Ann. des Sciences Naturelles*, 1831; Taylor's *Scientific Memoirs*, 1837.)

The fundamental division proposed by Ehrenberg gives two distinct classes of Infusoria, viz. those which appear to have in their body a complicated digestive cavity, consisting of a great number of cells [POLYGASTRICA], and those which have a simple digestive sac, and wheel-organs about the mouth. [ROTATORIA.] To these articles the reader is referred for a full statement of Ehrenberg's latest classification.

MICRU'RA. [VIPERIDÆ.]

MYCTYRIS. [PINNOTHERIANS.]

MIDAS (Zoology), M. Geoffroy's name for a subgenus of the small South American monkeys called *Outstittis*. [JACCHRS.] The common name for the species of this subgenus is *Tamarin*.

Midas Resalia.

Subgeneric Character.—Muzzle short, facial angle 60°.

forehead with an appearance of prominence, arising from the great angle of the upper edge of the orbits. Upper incisors contiguous, under incisors same size as the upper. Nails like claws, excepting those on the thumbs behind; tail as in *Jacchus*. General dental formula as in *Jacchus*.

There are seven species, of which we select as the example *Midas Rosalia*, the *Marakina*, or *Silky Tamarin*.

Description.—This pretty little monkey is entirely of a golden yellow, varying to a redder tint, and palest on the back and thighs. The hair, which is fine and silky, is so long about the head and neck as to form a ruff or mane, whence it has been called the Lion-monkey. Its beauty and gentleness render it a very interesting pet; but great care is required to keep it from damp, which is destructive to it. It is supposed to live almost entirely on trees, and to be squirrel-like in its habits.

Locality.—Guyana, and the south of Brazil from Rio Janeiro to Cape Frio.

Desmarest notices a red and black variety (Guyana), and one of a bright shining red from Brazil.

N.B. This must not be confounded with *Midas Leonina*, *Simia leonina*, Humb., the *Leoncito*, or *Leonine Tamarin*, which is probably the smallest monkey known. The last is brownish, and has a very well developed mane of that colour, which it bristles up when angry, so as to look like a little lion. The face is black, the mouth white, and the tail black above and white below. It inhabits the plains bordering the eastern slope of the Cordillera, and is rare.

MIDAS'S EAR. [AURICULA.]

MIDDELBURG. [ZEELAND.]

MIDDLE LATITUDE (Navigation), the mean of two latitudes. It is the distinctive name of a method called in navigation middle latitude sailing, which means, that in estimating the difference of longitude by means of the differences of latitude and the intermediate departure, this departure is supposed to be an arc of a parallel of longitude at the intermediate or middle latitude. (Riddle's *Naviga-tion*, in which a table may be found corrective of the results.)

MIDDLE VOICE is a term employed in Greek grammar to indicate a class of verbs which are called reflective in some other languages. The reflective meaning is supposed to be the original and main signification of the middle voice, but it is difficult in many of the middle verbs in Greek to trace the reflective notion. Although a separate voice, that is, a distinct mode of conjugation has been assigned to verbs with a middle signification, there are only two tenses in the Greek verb which have a form peculiar to the middle notion, namely, the first and second aorists in *σαμην* and *ομην*; which, in the model verb, are *ἐτυψάμην* and *ἐτυπόμην*. There are four tenses peculiar to the passive signification, namely, the two futures in *θησομαι* and *ησομαι*, and the two aorists in *θην* and *ην* (*τυφ-θήσομαι*, *τυπ-ήσομαι*, *ἐτίφ-θην*, *ἐτύπ-ην*). The future in *σομαι* (*τύπ-σομαι*, *λέγ-σομαι*), which is called in most grammars the future middle, has a passive signification, as well as a middle. (Monk on Eurip., *Hippol.*, l. 1458; *Quarterly Journal of Education*, vol. iv., p. 158.) The following table will make the matter clearer:—

Tenses common to the passive and middle significations.

Present	τύπτομαι.	Perfect	τίτυμμαι.
Imperfect	ἐτυπτόμην.	Past Perfect	ἑτέτύμην.
Future	τύψομαι.	Future Perfect	τετύψομαι.

Tenses peculiar to the middle signification.

1st Aorist	ἐτυψάμην.	2nd Aorist	ἐτυπόμην.
------------	-----------	------------	-----------

Tenses peculiar to the passive signification.

1st Aorist	ἐτίφθην.	2nd Aorist	ἐτύπην.
1st Future	τυφθήσομαι.	2nd Future	τυπήσομαι.

Since then so many tenses in the Greek verb have the same form both for the middle and passive signification, it becomes an interesting object of inquiry, whether we should assign the priority to the passive or middle notion? This question has usually been answered by grammarians in favour of the passive; but the comparison of other languages etymologically connected with the Greek, would lead us to a contrary supposition. Very few of the Indo-Germanic languages have a form peculiar to the passive signification; even in Sanskrit the passive verb is not considered by Hindu grammarians as a distinct voice, but is classed among the derivative verbs. There are however two voices in the Sanskrit verb, answering to the Greek active and middle, which are called respectively *parasmaipadam*

and *atmanēpadum*; the former answering to the active in Greek, and the latter having generally a reflective or medial but never a passive signification. The tenses of the passive verb are formed by prefixing the syllable *ya* to the person endings of the *atmanēpadum* conjugation. These person endings are evidently the same as those of the middle voice in Greek, as the following table of the present tense will show:—

	Sanskrit.	Greek.
Singular	kship-ê	τύπτ-ο, μαι.
	kship-a, sê	τύπτ-ε, σαι (afterwards τύπτ-εαι = τύπτ-υ).
	kship a, tē	τύπτ-ε, ται.
Dual	kship-â, vahê	τυπτ-ό, μεθον.
	kship-ê thê	τύπτ-ε, σθον.
	kship-êtê	τύπτ-ε, σθον.
Plural	kship-â, mahê	τυπτ-ό, μιθα.
	kship-a, dhê	τύπτ-ε, σθε.
	kship-a, ntê	τύπτ-ο, νται.

That the passive signification should in course of time have taken the place of the middle, will not appear surprising, when it is recollected that a reflective verb is actually used in many languages, where a passive is used in others to express the same thing. An instance occurs in such a phrase as *les bas se rendent ici*, stockings sell themselves here; and in the same manner in Italian we have such phrases as *si dicono molte cose*, many thing say themselves, or are said; *si loda l'uomo modesto*, a modest man praises himself, that is, is praised; *mi si domanda uno scudo*, a dollar demands itself of me, that is, is demanded of me. The same idiom occurs both in Spanish and Portuguese.

It has been the practice to deny to the Latin language the possession of a middle, except in the case of deponent verbs. But in such a phrase as *Rhenus Oceano miscetur*, the verb is rather of the middle than the passive character, and this certainly must be allowed when it is said of a soldier *induitur galeam*, or when a general *milites armari jubet*; or as in the line of Virgil (*Georg.*, iii. 219)—

Pascitur in magna fylva formosa juvenca.

The above explanation of the middle form or voice is one which has been proposed; still the matter may require further discussion. The truth is, that the classification of verbs into active and passive, or into active, passive, and middle, is a very imperfect one, and for the purposes of a philosophical exhibition of grammar a new classification is wanting. The expressions 'I walk,' 'I eat,' &c., are in signification allied to the middle voice, though the form of these words does not differ from the form 'I kill,' 'I cut,' &c. In order to express the notion of the person 'I' being 'killed,' some modification of the primitive form 'kill' must be made, and another modification may be necessary to express the act of 'self-killing.' Thus in French we have *il tue*, *il fut tué*, and *il s'est tué*. In the last instance the act of self-killing' is distinguished from the act of 'being killed' by the addition of a word. In the Greek language the present tense of the passive form may be used to express either the act of the person being killed, or killing himself. In the first and second aorist tenses a peculiar form is used to express the act of self-killing; but as this peculiar form has the characteristic termination of what is called a passive verb, and not of an active, it might be classed under the passive voice as a peculiar tense, and the term middle voice might be got rid of altogether.

MIDDLESEX, the metropolitan county of England, is bounded on the north by Hertfordshire; on the east by Essex, from which it is separated by the river Lea; on the south-east by Kent, and on the south by Surrey, from both of which it is separated by the river Thames; and on the west by Buckinghamshire, from which it is separated by the river Colne. Its greatest length is, from north-east to south-west, from the Lea near Waltham Abbey to the Thames opposite Chertsey, 28 miles; its greatest breadth, at right angles to the length, is, from near South Mimms on the great north road to Limehouse, 17 miles. Its area is estimated at 282 square miles. The number of inhabitants in 1821 was 1,144,531; in 1831, 1,358,330; showing an increase in ten years of 213,799, or about 19 per cent., and giving 4817 inhabitants to a square mile. It is the smallest of all the English counties, except Rutland; in amount of population it is exceeded, and that only in a small degree, by Yorkshire alone; in density of population it very far

exceeds any other English county. The courts of civil and criminal jurisdiction are held in London or Westminster, or at Clerkenwell, in the suburbs of London; but for parliamentary purposes Brentford, seven miles from Hyde-park Corner on the great western road, is the county town.

Surface; Geological Character.—The surface of the county consists for the most part of gentle undulations, affording a sufficient slope for the purposes of drainage. A range of hills extends along the northern or Hertfordshire border by Barnet, Elstree, Stanmore, and Pinner, averaging 400 feet in height above the level of the Thames. Another range of hills skirts the northern side of the metropolis by Hornsey, Highgate, and Hampstead; Harrow occupies an insulated eminence between these two ranges. That portion of the county which lies south-west of a line drawn from Brentford to Uxbridge is an almost unbroken flat, scarcely rising more than from 10 to 20 feet above the level of the Thames.

The county is chiefly occupied by the London clay. Enfield Chase, the most northern portion, and a strip along the western boundary by Harefield and Uxbridge, are occupied by the plastic clay, which here crops out. The high ground about Hampstead, Highgate, and Hornsey consists of Bagshot sand, a marine formation of unascertained depth covering the London clay. The thickness of the London clay is very variable. At Bromley near the Lea, in the south-east corner of the county, it was found to be only 44 feet (covered with 18 feet of alluvium), while at White's Club-house, St. James's, London, it was 235 feet. The thickness of the plastic clay in this county appears to be from 100 to 120 feet.

The county belongs entirely to the basin of the Thames, which forms its southern boundary. The Thames first touches the border just above Staines, at the junction of one of the arms of the Colne, and flows about six or seven miles to the southernmost point of the county near Shepperton, where (on the Surrey side) it receives the Wey. From the junction of the Wey it flows in a circuitous channel eastward 8 miles to Thames Ditton, above Kingston, and from thence 9 miles in a winding channel northward to Kew Bridge, just below Brentford. From Kew Bridge the Thames flows eastward 20 miles, with many bends, to the junction of the Lea, just above which it makes a circuit, nearly encompassing a marshy peninsula at the south-eastern angle of the county, called the Isle of Dogs. This river is crossed by several bridges: at Staines and Chertsey (both of stone), Walton (brick and stone), Hampton Court (wood), Kingston, Richmond, and Kew (all of stone), Hammersmith (a suspension bridge), and Putney and Chelsea (wood). There are six bridges in the metropolis: Vauxhall (an iron bridge), Westminster, Waterloo, and Blackfriars (all of stone), Southwark (an iron bridge), and London, the lowest on the river, a stone bridge. Between Rotherhithe and Wapping, about a mile and a half below London Bridge, a tunnel is in progress under the bed of the river. It has a double-arched roadway, with footpaths. The entrance at each end is to be by an inclined plane for carriages and horses, and a flight of steps for foot passengers. The river is navigable throughout for laden barges; but locks are required in the upper part to keep up the water. The lowest of these locks is at Teddington, between Kingston and Richmond bridges. Up to London Bridge the Thames is navigable for sea-borne vessels, and the space between that bridge and the junction of the Lea forms the port of London. [LONDON.] The banks of the Thames are for the most part low and flat, and in some places marshy. The Isle of Dogs would be overflowed every tide, if it were not protected by embankments.

The Lea forms the eastern boundary of the county, which it touches below Waltham Abbey. Its waters are, at the point of junction, divided between two or three channels, which reunite very soon after. Its course is southward through a belt of low marsh-land, 8 miles to the foot of Stamford Hill. In this part there is a navigable cut, distinct from the natural bed of the river, extending from Stewardstone below Waltham Abbey to the neighbourhood of Tottenham. The natural channel is in several parts divided so as to insulate portions of the marsh. From Stamford Hill the Lea flows south-east 6 miles by Lea Bridge, Old Ford, Bow, and Bromley, into the Thames. Below Lea Bridge it is divided into several channels, which reunite a little above the outfall. In one part (namely, between Lea Bridge and Old Ford) the navigation is carried on by an artificial channel. A navigable cut opens a com-

munication between the Lea at Bromley and the Thames at Limehouse, avoiding the tedious circumnavigation of the Isle of Dogs. There are several mills on those channels of the Lea which are not used for navigation.

The Colne forms the western boundary of the county. It first touches the border below Rickmansworth, and its waters, like those of the Lea, frequently flow in several channels, which enclose a number of islands. It flows southward past or near Uxbridge, West Drayton, Harmondsworth, and Colnbrook (Bucks), to its junction with the Thames above Staines. Its whole length on the border of this county is about 18 miles: it is not navigable, but is useful in turning a number of mills. Two channels from this river near Colnbrook communicate, one with the Thames at Hampton Court, the other with the Cran near the powder-mills at Hounslow; a third stream from a little above Staines flows into the Thames between Shepperton and Sunbury.

The Brent rises just within the northern border of the county, and, after crossing a corner of Hertfordshire north of Totteridge, flows by Finchley, Brent-street in Hendon, Kingsbury, Twyford, Hanwell, and Brentford, into the Thames. Its course, which is very circuitous, is about 18 or 20 miles: it is not navigable, except in some part of its lower course, where it forms part of the line of the Grand Junction Canal. The Cran rises between Harrow and Pinner, and after a very circuitous course of 19 or 20 miles past or near Ickenham, Cranford, and the powder-mills at Hounslow, joins the Thames at Isleworth.

The principal canal is the Grand Junction, which enters the county near Harefield, in the north-west corner, and runs southward along the valley of the Colne by Uxbridge to West Drayton: from this place it runs eastward across the Cran to the Brent near Hanwell: it then follows the valley of the Brent, and for the most part coincides with the channel of that river, till it joins the Thames near Brentford. About 18 miles of its course are in this county. A branch from this canal near Cranford runs north-east to Northolt, and from thence east-south-east by Twyford to Paddington, a distance of 12 or 14 miles. The main line and the Paddington branch have an average width of 43 feet, and a depth of 5 feet. There is only one lock between the wharf at Paddington and Uxbridge.

The Regent's Canal commences in the Paddington branch of the Grand Junction Canal, and passes along the north and east sides of the metropolis by the Regent's Park, Camden Town, Islington, Kingsland, Hackney, Mile End, and the Commercial Road, into the Thames near Limehouse. Its length is 8½ miles, with a fall of 90 feet: it has twelve locks exclusive of the tide-lock. It passes under Islington and the New River by a tunnel, and has one or two short branch cuts or basins in its course, one of which (Sir Geo. Duckett's canal) communicates with the Lea near Old Ford.

The New River, an artificial cut designed to supply the metropolis with water, enters the county on the north side between Enfield and Cheshunt, and is conveyed in a very winding channel to a reservoir at Pentonville, on the north side of London. [MIDDLETON, SIR HUGH.]

The south-western road (to Salisbury, Exeter, &c.) leaves London by Hyde-park Corner, and runs by Hammersmith, Brentford, Hounslow, and Bedfont, to Staines, where it crosses the Thames into Surrey. The Portsmouth road, branching from this near Hyde-park Corner, crosses the Thames at Putney Bridge; and the western (Bath and Bristol) road, branching from it at Hounslow, crosses the Colne at Colnbrook. The Oxford and Birmingham road leaves the metropolis at Tyburn turnpike, and passes through Shepherd's Bush, Acton, Hanwell, Southall, and Uxbridge, beyond which it crosses the Colne into Buckinghamshire. The great north road (to Derby, Leeds, Manchester, &c.) leaves London by Islington, and passes through Highgate, Fryern and Chipping Barnet, to South Mimms, where it branches off, one branch passing by St. Alban's, the other (the York road) passing by Hatfield. Another York road leaves London by Shoreditch church, and passes through Kingsland, Tottenham, Edmonton, and Enfield. Of the Norfolk and Suffolk roads, one leaves London by Shoreditch church, passing through Hackney, and crossing the Lea at Lea Bridge into Essex; another leaves by Whitechapel church, and crosses by Bow Bridge into Essex. These are the most important roads; but there are others well frequented. One (the Edgware road) leads from Tyburn turnpike by Paddington and Edgware into

Hertfordshire, joining the north road at St. Albans; another passes by Harrow and Pinner to Rickmansworth; and a third, called 'the Green Lanes,' leads by Stoke Newington and Winchmore Hill to Enfield.

The Birmingham Railway has its London terminus at Euston Grove, on the north side of the metropolis, and runs past Harrow to Watford in Hertfordshire; and the Great Western Railway has its London terminus at Paddington, and runs by Acton, Ealing, Hanwell, and Southall, to Maidenhead. The Eastern Counties Railroad commences at Mile End and runs by Bow and Stratford across the Lea into Essex: it is to communicate with Norwich and Yarmouth. There is another railway in progress, called the Northern and Eastern Railway, which also commences at Whitechapel, and is intended to communicate with Cambridge. Acts have been obtained for the Commercial Railway, to run from the eastern side of London to Blackwall; and for the Bristol, Birmingham, and Thames Junction Railway.

Agriculture.—The soil of this county is of three distinct qualities: poor sand and gravel on the tops of some of the hills and in various spots in the plain; a heavy poor clay in the north and north-west portion, which is chiefly covered with permanent grass, enriched by repeated application of manure; and a good fertile loam over a bed of gravel, and sometimes of peat, along the plain in which the Thames flows. To these must be added some rich deposits from the Thames, of a lighter and more muddy nature, which are admirably adapted for garden ground, and have been almost entirely converted into a rich black vegetable mould, by an abundant application of dung, from time immemorial.

The surface, with the exception of a few hills on the northern side of London, none of which rise more than 400 feet above the Thames, may be described as a plain, almost perfectly level as it approaches the Thames, but with a sufficient fall for the waters to prevent any of it being marshy. The Thames has been long kept within its present channel by artificial embankments, wherever these were necessary. But it is evident that, in times beyond memory, it frequently changed its bed, which accounts for the irregular deposition of gravel in various places, and the uniform covering of loam which is found above it.

Nearly the whole of the county lies over the blue clay, which is known by the name of the London clay: and the hills which rise above it are formed of a basis of clay covered by a poor ferruginous sand and gravel. In various places the clay appears near the surface at a level considerably above the loamy deposit mentioned above.

The stiff clay is altogether unfit for arable cultivation, until its nature is altered and corrected by the addition of chalk, lime, and ashes; most of it therefore remains undisturbed by the plough. When the commons, which are now mostly enclosed, remained open, the grass was poor and of little value; but that part which has been long enclosed has a coat of rich mould over it, caused by the annual application of dung to produce a sufficient crop of grass to make hay of, and its fertility is so much increased as to afford two good crops every year. Hay-making is nowhere better understood than in Middlesex. The value of hay so near the metropolis, and the abundant supply of labourers, enable the occupiers of grass-land to take advantage of a few days of fine weather to secure their hay. The mode of proceeding, as it is given in the Report of the Agriculture of Middlesex, by Middleton, has generally been held out as a pattern to all farmers. It is no doubt excellent where labourers are plentiful, but would be attended with some risk where the number is limited, and the extent of grass to be mown is considerable. The principle is, to expose the grass as much as possible to the sun and wind by keeping it constantly shaken up and moved, which is much facilitated by the use of the hay-making machine. It may thus be carried in a very few days, and stacked in a dry state; and when it is cut out, it appears of a fine green colour, not much changed by heating. The hay-ricks are generally large and neatly finished, the sides being pulled and trimmed smooth, and the top well thatched with straw. When the old hay is carried to market, it is tied up in neat trusses weighing 56 lbs. each, and 36 such trusses make a load. The trusses of new hay are made of 60 lbs. weight. It is called old when it has been in the rick three months. Some enclosures of pasture-land are made profitable by taking in horses to graze when they require rest and green food after having been overworked; but for this purpose the marsh pastures bordering on Essex along the Thames are

preferred. There the soil is naturally rich, and requires little manure to recruit it.

The arable portion of the county lies chiefly towards Buckinghamshire, and between the Great Western Railway and the Thames. Some extremely good loams of considerable depth on a bed of flinty gravel, well adapted to every kind of agricultural produce, occur in several places. The lighter portions are mostly laid out in orchards, market-gardens, and nursery-grounds. Almost the whole of the land in the parishes of Chelsea, Hammersmith, Chiswick, Isleworth, and Brentford is taken up by such gardens. Here the spade is the principal instrument of cultivation. [GARDEN HUSBANDRY.]

Beyond Hounslow, including what was formerly Hounslow Heath, the land is cultivated more extensively, by farmers properly so called; and some of these occupy from 200 to 1500 acres. Here every improvement in the management of the soil is readily adopted; the best implements are in use: and it only requires a view of the fields along the two great branches of the western road to perceive that the land is kept clean and that the crops are good. The system is greatly modified by the short distance from an inexhaustible source of manure. It is not necessary to keep many head of cattle or great flocks of sheep to produce manure for the land. A smaller portion of the farm is devoted to raise food for cattle. Roots are disposed of to cowkeepers in London; but the expense of carriage is a great drawback to the profit. The produce is generally conveyed in waggons with four horses, or in tumbrils with two or three. A man and a boy are required in either case. Light single-horse carts, such as are used in Scotland, would be more economical, if one man could take charge of several carts, as is usually done there, and also in France; but the great traffic on the roads near London renders this very dangerous, and the law prohibits it. Every waggon with four horses, a man, and a boy, costs the proprietor from 17. to 17. 5s. for every working day. If half of this be placed to the account of the load taken to London, and the other half to that of the manure brought back, it will appear that, however convenient it may be to be able to procure manure at any time, and in any quantity, it is not so cheaply obtained as might appear at first sight. The number of horses required for a Middlesex farmer is much greater than where the land lies at a greater distance from any large town. The stable-dung is brought in a very fresh and loose state; it is put together in large heaps, where it heats very soon, and is then turned over, and sometimes covered with earth or sods. By the time it is carried upon the land it will have cost the farmer not much less than 17. per waggon-load of three tons. Upon the lighter loams, which are improved by the treading of sheep, it is probably more advantageous to raise turnips, and fold the sheep on them, than to sell the turnips and buy town manure.

The course of crops on the farms in Middlesex is not so regular as in many other counties; but the alternation of white and green crops is very generally adopted. Naked fallows are almost entirely disused, even on the heavier soils. The land is kept clean by tares cut green, peas gathered in the pod, beans, and similar crops, which allow of ploughing and cleansing the land in summer, and sowing roots afterwards. The crops are usually drilled and well hoed: the principal are barley, clover, wheat, beans, oats—often in this order. Turnips and mangel-wurzel are not so extensively cultivated as they are where manure must be made on the farm. A succession of tares, to cut green for the horses, is indispensable; some of these are occasionally taken to London early in the season, and sell well in small quantities, tied up in bundles. Potatoes are not planted to so great an extent as might be supposed, considering the great consumption of this root in London: the reason is, that the market is fully supplied by cargoes which come by sea from Scotland, Yorkshire, Devonshire, and Jersey, where labour is cheaper and the land does not pay so high a rent. Potatoes consume much manure, whatever may have been pretended by some; and the corn which comes after them is generally weaker and less productive. When the rent of good land in Middlesex is taken into consideration, the carriage of manure, and the bulk of the crop to be carried to market by land, it will be found that, however valuable may be the produce of an acre of potatoes well cultivated, the expense is so great that the net return is little more than that of wheat, beans, or clover. It is very seldom that potatoes are planted as a substitute for the old fallow. Beans or peas in wide rows, and carefully hoed, are much

preferable. Cole or rape is frequently sown on stiff loams, instead of turnips, and fed off with sheep. If the rape is drilled and hoed, it will clean the land, and forms an excellent preparation for wheat. It should have plenty of manure, which will be decomposed and well mixed with the soil when the wheat is sown. Thus the latter crop cannot fail to be good.

The grass-land is everywhere well managed. The surface is kept intersected with water-furrows wherever the soil is impervious to water, so that it never stagnates in winter. The grass is generally cut twice in the season, and made into hay; but the land is well manured, generally after the first mowing, about the middle of June. The Midsummer rains wash it in, and the aftermath is much increased by it. Two tons of hay at the first mowing, and one ton at the second, may be considered as the average produce of a statute acre. The rent of grass-land about ten miles from London, including rates and tithe, averages from 4*l.* to 6*l.* per acre. Nearer London grass-land lets very high for milch cows, and likewise for pleasure horses to graze in. But the rapid increase of buildings has converted so many fields into streets, or broken up the surface for the sake of the brick-earth, that the green meadows are every year farther from the centre of the metropolis.

Every breed of animal is to be met with in Middlesex. Horses and milch cows are the most common, as the most useful. The cart-horses are generally fine and strong. Some large horses, a little too heavy for a carriage and too slow for stage-coaches, but which make excellent cart-horses, are brought to London in large quantities by dealers, who collect them in the northern and midland counties. The dairy cows are chiefly of the large Holderness breed or the short-horn. Ayrshire cows have been tried, and, as far as milk goes, they are fully equal to the other breeds, taking the quantity of food consumed by each into consideration; but they do not yield such heavy carcasses to the butcher when fattened off. The most approved system of London dairymen is to let a cow be milked till she goes dry, and never allow her to go to the bull. By very high feeding she will increase in flesh while she gives milk, and by the time she is dry will be very fat. Private families in the neighbourhood of London, who have grass-land, have a predilection for the small Alderney cows, which give a small quantity of extremely rich milk. They are very quiet animals, and may be tethered or led about to graze in a halter. On good pasture they are very profitable. Alderney dairies have been established; but most of them have no title to that name, the large cows having soon superseded the smaller.

The price of labour in Middlesex is not so high, when compared with that of the adjoining counties, as might be expected. Very near London market-gardeners pay their labourers from 15*s.* to 1*l.* per week for day-labour; but as much as possible is done by the task. Digging and trenching are done by the square perch, the price varying according to the soil and the depth of the work. A good workman will earn 3*s.* 6*d.* or more in a day, but for this he must work hard. A mower has from 3*s.* to 6*s.* per acre for mowing grass, 2*s.* 6*d.* to 3*s.* 6*d.* for clover, and the same for oats or barley; tares and peas are hooked at from 3*s.* to 5*s.* per acre; wheat and rye are *fagged*, that is, cut close to the ground with a large reaping-hook, for 10*s.* to 18*s.* per acre, as the crop may be more or less heavy; beans for 6*s.* to 9*s.*; thrashing wheat costs 4*s.* to 5*s.* per quarter, and 1*s.* per load for tying up the straw; oats are thrashed for 2*s.* or 2*s.* 6*d.*; beans and pease, 1*s.* 6*d.* to 2*s.*; hay is cut, trussed, and every truss weighed, for 2*s.* 6*d.* to 3*s.* the load of thirty-six trusses; turnips hoed, first time, 6*s.* or 7*s.*; second time, 5*s.* Women making hay, and gathering peas or fruit, earn about 1*s.* per day.

These were the prices about thirty years ago; they had increased with the price of corn and meat, but have again fallen. At this moment they are rather on the increase; yet the above prices may be relied upon as fair averages in a circle of twenty-five miles round London. The principal weekly markets in Middlesex, out of London, are Barnet, every Monday; Southall and Finchley, on Wednesday; Uxbridge, Brentford, Hounslow, and Edgware, on Thursday; Staines, on Friday; and Enfield, on Saturday. Uxbridge is a great corn-market; Southall chiefly for cattle and sheep: those which remain unsold are sent to Smithfield on the Friday. Staines is also a good corn-market.

There are fairs at Brentford, May 17, 18, 19, and Sept. P. C., No. 936.

12, 13, 14; Enfield, Sept. 23, Nov. 30; Hounslow, Trinity Monday, and Monday after Sept. 29; Staines, May 11; Uxbridge, July 31, Sept. 29, Oct. 19; Barnet fairs, April 8, and September 4, are noted for young cattle of every description.

Divisions, Towns, &c.—Middlesex is divided into six hundreds, as follows:—

	Acres.	Pop. in 1831.
Edmonton, N.E.	31,410	26,930
Gore, N.	28,660	11,315
Elthorne, N.W.	35,690	20,091
Isleworth, S.W.	9,280	13,568
Spelthorne, S.W.	23,500	15,212
Ossulston, S.E., including		
Finsbury division	11,934	151,409
Holborn "	7,808	316,255
Kensington "	19,220	87,961
Tower "	8,988	359,864
London city	600	123,683
Westminster city	2,500	201,842
Militia		200
	179,590	1,358,330

The cities of London and Westminster are locally in Ossulston hundred. The suburbs of London form the newly constituted parliamentary boroughs of Marylebone, Finsbury, and the Tower Hamlets.

There are four market-towns, Barnet, Brentford, Staines, and Uxbridge; besides Edgware, Enfield, and Hounslow, the markets of which have been discontinued; and a number of other places, which, though not ranking higher than villages, derive, from their proximity to the metropolis, sufficient interest and importance to require notice. [BARNET; BRENTFORD; CHELSEA; LONDON.]

Staines is in Spelthorne hundred, 16½ miles from Hyde-park Corner, on the road to Salisbury and Exeter. The parish contains an area of 1710 acres, with a population of 2486. The principal street extends half a mile along the road, and leads to the Thames. Many of the houses in the main street are good. A new stone bridge has been built over the river. The church is a neat modern structure, with a square embattled tower, and there are some dissenting places of worship. The market-house is a small building near the bridge. The market is on Friday, and there are two yearly fairs. There are several flour-mills near the town. The living is a vicarage united with the chapelries of Laleham and Ashford, of the joint annual value of 425*l.*, with a glebe-house. There were, in 1833, one infant-school, with 90 children; a school of industry for 26 girls, a Lancasterian school with 80 boys, and a national school with 40; one other day-school with 30 boys, three boarding-schools with 86 children, and three Sunday-schools, with 193 children of both sexes. There is also a Literary and Scientific Institution.

Uxbridge is in the parish of Hillingdon, in Elthorne hundred, about fifteen miles from Tyburn turnpike, on the Oxford road. It was formerly a place of strength, and a corporate town, and in the civil war of Charles I. was the scene of an unavailing negotiation for peace between the commissioners of the king and those of the parliament. The mansion in which the conferences were held is still standing. The area of Hillingdon parish is 4720 acres; the inhabitants, in 1831, amounted to 6885, of whom 3043 were in the chapelry of Uxbridge. The town consists of one principal street, about a mile in length, along the Oxford road, and two or three smaller ones. There are in the principal street two bridges over the arms of the river Colne, and one over the Grand Junction Canal. There are a commodious market-house of brick, supported on wooden columns; a chapel behind the market-house, built of flint and brick, and destitute of architectural beauty, capable of holding 800 persons; and several dissenting meeting-houses. The market, which is on Thursday, is one of the most important corn-markets in the kingdom. A second market, for provisions, is held on Saturday, and there are several yearly fairs. There are warehouses and wharfs on the Grand Junction Canal, and there are many flour-mills. Considerable business is done in the town, and brick-making is largely carried on in the neighbourhood.

The perpetual curacy of Uxbridge is of the clear yearly value of 111*l.*, with a glebe-house. There were, in 1833, a Lancasterian school, with 187 boys; a school of industry, with 107 girls; three other day-schools, with 114 children;

three boarding and day schools, with 87 children; and three Sunday-schools, with 515 children.

Edgware is in Gore hundred, 8 miles from Tyburn turnpike, on the road to Watford and Aylesbury. The parish has an area of 1990 acres, with a population, in 1831, of 591. The place has one long straggling street, but contains some respectable houses. The church is of brick, and was built about the middle of the last century; the tower, more antient, is of flint and stone. The market, which was formerly held on Thursday, has been discontinued for many years. The west side of the main street is in the parish of Stanmore Parva, or Whitchurch. Near this place is Canons, a neat villa, erected on the site and from the materials of a stately mansion built by the duke of Chandos, whose tasteless vanity, as displayed in this establishment, was bitterly satirised by Pope in his 'Moral Essays' (Ep. iv). The church of Stanmore Parva, close to the park of Canons, was decorated by the duke. Little Stanmore has an area of 1420 acres, with a population, in 1831, of 876. The living of Edgware is a vicarage, of the clear yearly value of 493*l.*, with a glebe-house; that of Stanmore Parva is a perpetual curacy, of the clear yearly value of 267*l.*, with a glebe-house. The two parishes had, in 1833, one infant or dame school, with 41 children; eight day-schools (one endowed), with 152 children; and two Sunday-schools, with 91 children.

Enfield is in Edmonton hundred; that part which is called Enfield Highway is 9½ miles from Shoreditch Church, on the York and Edinburgh road. Enfield manor-house was the residence of Elizabeth (afterwards queen) for a short time, during the reign of her brother Edward VI.; and she resided at Enfield, at the manor-house or at Elsyng-hall, at several periods during her reign. Of the manor-house one room on the ground-floor remains as in the queen's time. Elsyng-hall has disappeared, and its exact site is not known. The parish of Enfield has an area of 12,460 acres, with a population, in 1831, of 8812, about one-third agricultural. The houses constitute two principal groups; and many of them are well built. The church is an antient structure, comprehending chancel, nave, and two aisles, with a low embattled tower. There are a chapel-of-ease, lately erected, and several dissenting places of worship. Edward I. granted a charter for a market on Monday, and James I. for one on Saturday; but they have long fallen into disuse. There are two yearly fairs. There are in the parish a royal manufactory for fire-arms (partly carried on here and partly at Waltham Abbey), a manufactory for finishing crape, and two or three other trading establishments. The Lea navigation and the New River pass by or through this parish. Petty sessions and a Court of Requests are held here. The living of Enfield is a vicarage, of the clear yearly value of 1174*l.*, with a glebe-house. There were in the parish, in 1833, two infant schools, with 145 children; a school of industry, with 45 girls; seven other day-schools, with 181 children; five boarding and day schools, with 152 children; and four Sunday-schools, with 635 children.

Enfield Chase, formerly a large chase or park north-west of the town, extending into several parishes, is now entirely enclosed.

Hounslow is in the two parishes of Isleworth and Heston, in Isleworth hundred, but chiefly in Heston. The area of the two parishes is 6840 acres; the population, in 1831, was 8997. The town, which is 10 miles from Hyde-park Corner, is at the point where the Bath and Bristol road branches off from that to Exeter and Salisbury, and consists of a long street on the Exeter road, irregularly paved, and lighted with gas. Hounslow had an antient priory of the order of the Holy Trinity, which at its suppression, A.D. 1530, had a revenue of 80*l.* 15*s.* gross, or 74*l.* 8*s.* clear. The conventual chapel, long used as a chapel-of-ease, was taken down a few years since, and has been replaced by a new church, capable of seating above 1000 persons. The market, formerly held on Thursday, has been discontinued for some years. The chief business of the town has of late years arisen from its situation on a great thoroughfare, but this business is nearly destroyed since the opening of the Great Western Railway. There are some powder-mills and a flax-dressing-mill near the town. Adjoining to the town, on the west, was formerly an extensive heath, notorious for highway robberies. On this heath the army of James II. encamped before the Revolution. There are large cavalry barracks and an exercise-ground on what was

formerly the heath. The remainder is now enclosed. The living of Hounslow is a perpetual curacy, of the clear yearly value of 125*l.* There were in Heston parish, in 1833, two infant schools, with about 321 children; three day-schools, with about 108 children; one boarding-school, with 19 boys; and one Sunday-school, with 70 children.

Tottenham is in Edmonton hundred, about 4 miles from Shoreditch church, on the York road. The parish, which is divided into four wards, has an area of 4680 acres, with a population, in 1831, of 6937. The main street is formed of good houses irregularly ranged along the road. In this street is a brick cross, erected A.D. 1600, in place of a former wooden one. The church is on a small eminence a short distance west of the village, and is an antient building, with a square embattled tower covered with ivy. The font is of great antiquity, and there are many monuments. A new church of considerable size has been built on Tottenham Green, and there are several dissenting meeting-houses. Bruce Castle (now occupied as a school) is a brick mansion, rebuilt in the latter part of the seventeenth century. A detached brick tower, which covers a deep well, is the only remain of the previous edifice, which was built by the Comptons early in the sixteenth century. The edifice takes its name from a castellated mansion, the residence of Robert Bruce the elder, father of the king of Scotland of that name, which antiently occupied the site. The river Lea forms the eastern boundary of the parish. There are extensive flour and oil mills. The living of Tottenham is a vicarage, of the clear yearly value of 978*l.*, with a glebe-house. The chapelry attached to the new church is of the clear yearly value of 309*l.*, and is in the gift of the vicar. There were, in 1833, two infant schools, with 85 children; an endowed free grammar-school with 80 boys; a 'blue-coat' school, with 60 girls, and a 'green-coat' school, with 40; two Lancastrian schools, with 283 children; a Catholic school, with 65 children; and several private day and boarding schools. There were also four Sunday-schools, with about 450 or 460 children.

Edmonton is on the York road, 7 miles from Shoreditch church, between Tottenham and Enfield. The parish has an area of 7480 acres, and is divided into four wards or 'streets,' beside an allotment of Enfield Chase assigned to this parish. The population, in 1831, was 8192. The village of Edmonton consists of two principal groups of houses, called Fore Street, or Upper Edmonton, and Church Street, or Lower Edmonton, extending along the north road for more than a mile, and consisting of some respectable ranges of houses, with detached mansions and villas. Southgate, a detached village west of Edmonton, is in 'South Street,' one of the four wards, and contains many residences of a superior description: among them is Minchenden House, belonging to the duke of Buckingham.

The parish church is for the most part of modern date, but the tower and some other portions are of greater antiquity; there are some antient monuments. There are chapels at Southgate and on Winchmore Hill, and several dissenting places of worship. The living of Edmonton is a vicarage, of the clear yearly value of 1550*l.*, with a glebe-house. The chapolries of Southgate and St. Paul, Winchmore Hill, are of the clear yearly value of 180*l.* and 100*l.* respectively, and are in the gift of the vicar of Edmonton. There were in the parish, in 1833, an endowed day-school, with 106 children, 60 of whom were clothed; another endowed day-school, with 72 girls; three day-schools, partly or wholly supported by charitable contributions, containing 233 children; eight other day-schools, with 117 children; ten boarding-schools, with 460 children; two day and Sunday schools, with 253 children; and one Sunday-school, with 184 children. Wyer House, in the parish of Edmonton, about a mile north-west of the village, is a fine old mansion-house built in the early part of the seventeenth century.

Harrow-on-the-Hill is in Gore hundred, 10 miles from Tyburn turnpike, on the road to Rickmansworth. The parish (including the hamlet of Harrow Weald and Green Hill) has an area of 9870 acres, with a population, in 1831, of 3861. The village is irregularly laid out. It derives its celebrity and chief support from its grammar-school, which was founded, under letters-patent of queen Elizabeth, by John Lyon, a wealthy yeoman of this parish, A.D. 1571. There are considerable estates which were left by J. Lyon for the support of the school and other charitable purposes. The school contained, in 1833, about 250 scholars:

it is free to all boys of the parish of Harrow, but there are very few who take advantage of this opportunity; the scholars are chiefly the sons of the nobility and gentry. Many eminent men have been educated at Harrow: as Bruce, the Abyssinian traveller, Sir William Jones, Richard Brinsley Sheridan, the late Lord Byron, Dr. Parr, and many others. The parish church is a spacious structure on the summit of the hill: there are some small portions in the Norman style; and at the west end is a lofty tower, with a spire. The grammar-school is near the church. There are some dissenting meeting-houses; there are two chapels-of-ease, one at Pinner (which is considered as a distinct parish), and the other at Harrow Weald, a group of houses about two miles north of the village. The living of Harrow is a vicarage, of the clear yearly value of 627*l.*, with a glebe-house. The vicar has the right of presentation to the perpetual curacy of Pinner, which is ecclesiastically dependent on Harrow, and is of the yearly value of 100*l.* Harrow and Pinner are in the peculiar jurisdiction of the archbishop of Canterbury. There were in the parish, in 1833, three infant or dame schools, with 93 children; four day-schools, supported by subscription, with 197 children; two boarding-schools, with 76 children; and four Sunday-schools, with 409 children.

Twickenham is in Isleworth hundred, on the bank of the Thames, 10 miles from Hyde-park Corner. It has derived celebrity from its being the residence of Alexander Pope and several other eminent persons. The parish has an area of 2140 acres, with a population in 1831 of 4571. The village is irregularly laid out, but contains a number of genteel residences. The church is near the river, and is a plain brick structure, built in the early part of the last century, with an ancient embattled tower. It contains monuments erected by Pope to the memory of his parents, and by bishop Warburton to Pope himself. There is a chapel-of-ease, erected A.D. 1720 or 1721, between Twickenham and Richmond, and one or two dissenting meeting-houses. Among the private residences are Strawberry Hill, and the house of Sir Wathen Waller, popularly termed 'Pope's Villa,' because it occupies the site of the poet's residence. Strawberry Hill was in great part erected by Horace Walpole, lord Orford, and is a medley of castellated and ecclesiastical Gothic architecture. There are powder and oil mills. The village is much frequented by visitors from London. The steam-boats which ply between London and Richmond frequently proceed up to 'Twickenham ait,' a small island in the river Thames, comprising a few acres chiefly laid out in pleasure-grounds. There is much garden-ground in the parish, the produce of which is sent up to the London market. The living is a vicarage of the clear yearly value of 717*l.*, with a glebe-house. There were in the parish, in 1833, an infant or dame school of 20 children; an endowed day-school with 166 children; three day-schools, partly supported by charitable contributions, containing 104 children; five other day-schools, with 154 children; and five boarding-schools, with 110 children.

Isleworth, adjoining Twickenham on the north side, is in Isleworth hundred, 8½ miles from Hyde-park Corner. The parish has an area of 3120 acres, with a population of 5590. At Sion or Syon, in this parish, was formerly a monastery of Bridgetine priests and nuns, founded A.D. 1114 by Henry V., and originally settled at Twickenham. The yearly revenues of this house at the dissolution were 1944*l.* 11*s.* 8*d.* gross, or 1731*l.* 8*s.* 4*d.* clear. In the walls of this monastery after its desecration, Catherine Howard, queen of Henry VIII., was confined shortly before her execution. The site was granted by Edward VI. to the Protector Somerset, who commenced the present mansion of Sion House, which has received great additions and alterations from the dukes of Northumberland, the subsequent proprietors. This noble residence contains some valuable portraits. The village of Isleworth is on the bank of the Thames opposite to Kew Gardens, and consists of several substantial villas and residences, with others of less pretension. The church, on the bank of the Thames, is of brick, and was rebuilt A.D. 1705 or 1706; the tower, more ancient, is of stone. There are some dissenting places of worship. The chief business of the parish is gardening; great quantities of raspberries and strawberries are grown for the London market. There are two flour-mills and a brewery. There are three ranges of almshouses in the parish. The living is a vicarage of the clear yearly value of 681*l.*, with a glebe-house. There were, in 1833, one infant-school, with from 50

to 70 children; an endowed school, with 150 children; a day and Sunday school, with 30 girls; and a Sunday-school, with 126 children; besides a large day-school in Hounslow (which is partly in this parish), supported partly by subscription.

Hampton is in Spelthorne hundred, about 15 miles from Hyde-park Corner. The parish, including the hamlet of Hampton Wick, has an area of 3190 acres, with a population in 1831 of 3992, of whom 1463 were in Hampton Wick. In this parish is the royal palace of Hampton Court, the site of which was once the possession of the Knights Hospitallers. On the suppression of the Order the fee of the manor was retained by the crown. Cardinal Wolsey took a lease of the manor from the prior of St. John's before the dissolution, which lease he surrendered to the king Henry VIII., who formed a royal park or chace, comprehending Hampton and several other parishes, which he enclosed and stocked with deer. This chace was in the succeeding reign broken up on the remonstrance of the aggrieved parishes, but the crown has since retained paramount authority over all game within its limits. While Wolsey held the lease of the manor he pulled down a mansion which stood here, and erected in its place a sumptuous palace, which Henry VIII. subsequently enlarged. Here Edward VI. was born, and his mother queen Jane Seymour died. This palace was the scene of the celebrated conference of 1603-4 between the Presbyterian clergy and the bishops and other Episcopal clergy, at which the king James I. was moderator, and the lords of the council were auditors. Charles I. resided here during part of his confinement, and Cromwell, Charles II., and James II. made it their occasional residence. William III. rebuilt a considerable part of the palace, and laid out the gardens and park in their present form. Since the time of George II. it has not been the abode of royalty, and is now occupied by private families who have grants of residence from the lord-chamberlain. The number of residents, including servants, is stated to be 700. The palace consists of three principal quadrangles, with some smaller courts. The chapel, the great hall, and some of the subordinate chambers and domestic offices are part of the building erected by Wolsey and enlarged by Henry VIII. The great eastern and southern fronts are the most modern parts of the building; the eastern front has an extent of about 330 feet, the southern of 328 feet. These portions were erected by Sir Christopher Wren, but are neither in keeping with the more ancient portions of the structure, nor distinguished by any great beauty. The palace contains a number of pictures by the old masters, but the Cartoons of Raffaele constitute its chief treasure. The gardens are laid out in very formal taste. The park has several avenues and fine clumps of trees. Bushey Park and lodge are an appendage of Hampton Court Palace; the lodge was the residence of William IV. when duke of Clarence, and now belongs to the queen-dowager for her life.

The village of Hampton has some substantial houses and handsome villas; among the latter is that which belonged to Garrick. Hampton races are held on Moulsey Hurst, on the opposite side of the Thames. The living of Hampton is a vicarage of the clear yearly value of 356*l.*, with a glebe-house. Hampton Wick is a chapelry of the clear yearly value of 87*l.*, in the gift of the vicar of Hampton. There were, in 1833, in the whole parish, nine day-schools (one endowed and one school of industry), with about 350 children; seven boarding-schools, with 94 children; and three Sunday-schools, with 76 children.

Hammersmith is in Kensington division of Ossulston hundred, 4 miles from Hyde-park Corner. The chapelry of Hammersmith, a dependency of Fulham parish, has an area of 2140 acres, with a population, in 1831, of 10,222. The principal street extends nearly two miles along the western road, and consists of several ranges of good modern houses. An elegant suspension-bridge crosses the Thames at this place. There are two churches: one erected in 1631, a spacious brick building; the other a Doric edifice, built within the last few years. The Dissenters have several places of worship, and the Catholics have a chapel and a convent of Benedictine nuns. Brandenburgh House, a villa erected by Sir Nicholas Crispe in the seventeenth century, and improved by subsequent occupants, was the residence of the late queen Caroline during her last abode in England. She died here, and after her death the house was pulled down. There are large nursery-grounds in the parish, and brick-making is extensively carried on. The living of Ham-

mersmith is of the clear yearly value of 310*l*. There were in the chapelry, in 1833, an endowed school called 'Latymer's school,' with 80 boys; a charity school for 50 girls, a school of industry with 57 girls, three other charity schools (one of them supported by Catholics), with 90 children; twenty-nine other day-schools, with 532 children; eighteen boarding-schools, with 466 children; and eight Sunday-schools, with 572 children.

Fulham, 4 miles from Hyde-park Corner, is in the same hundred and division as Hammersmith. The parish, exclusive of the chapelry of Hammersmith, has an area of 1820 acres, with a population, in 1831, of 7317. It was the scene of some military movements in the war between Charles I. and the parliament, A.D. 1642; and in 1647 the council of officers and agitators sat at Fulham and Putney (a village in Surrey on the opposite bank of the Thames), to overawe the parliament and watch the king, who was then in confinement at Hampton Court. The village contains many good houses and villas; the manor-house is the residence of the bishop of London. The church is of stone, and has a stone tower in the decorated English style. There is a proprietary chapel, built by Richard Hunt, Esq., A.D. 1813, between Fulham and Hammersmith.

The bridge over the Thames at this place is of wood. There are extensive market-gardens in the parish, which are noted for the growth of asparagus. The living is a vicarage of the clear yearly value of 1135*l*., in the gift of the bishop of London. There were in the parish, in 1833, two infant schools, with 159 children; two national schools, with 249 children; three charity-schools, with 72 children; eleven other day-schools, with 213 children; ten boarding-schools, with about 207 children; and one Sunday-school with 60 to 80 children.

Kensington, in the same division and hundred as the preceding parishes, is now a suburb of London. The parish, with the extra-parochial chapelry of Twyford, has an area of 2980 acres, with a population, in 1831, of 20,945. Part of the chapelry of Knightsbridge is in Kensington parish. The principal street of Kensington consists of ranges of well-built houses extending along the great western road; and there are other streets. Brompton and Little Chelsea, on the south, and Kensington gravel-pits, on the north, are in the parish. There is at Kensington a royal palace, built on the site of a residence belonging to the family of Finch, earls of Winchelsea and Nottingham, from whom it was purchased by William III. That prince converted the dwelling-house into a palace, rebuilding the principal parts, and making many additions to it, which succeeding princes have augmented. The palace is of red brick, ornamented with columns and coignes of stone, and consists of three principal quadrangles. The suites of apartments are noble and extensive, and are adorned with many fine paintings by Flemish and English artists. The gardens and grounds, which are agreeably laid out, are three miles in circuit. There are barracks for detachments of the guards. Several members of the Royal family have apartments within the palace. Holland House, an antient mansion, chiefly in the Elizabethan style, was the residence of Addison, who died here; and much of the early life of Charles James Fox was passed here. It is now the residence of Lord Holland: it contains some interesting portraits. Campden House is another antient residence in the same style. Kensington Church, a large modern brick building, is near the principal street: new churches have been erected in Addison Road and at Brompton, and there is a chapel-of-ease at Brompton, erected about seventy years ago. There are dissenting and Catholic chapels. The living is a vicarage, of the clear yearly value of 1242*l*., with a glebe-house. To the new churches in Addison Road (St. Barnabas) and Brompton (Trinity Church) are annexed curacies, of the respective value of 405*l*. and 639*l*., in the gift of the vicar of Kensington. There were, in 1833, five infant or dame schools, with 44 children; a national school, with 290 children; a school for 17 girls, supported out of the parish rates; two schools, partly or wholly supported by charitable contributions, with 104 children; twenty-three other day-schools, with 489 children; forty-nine boarding-schools, with 827 children; and three Sunday-schools, with 265 children. There were also two proprietary grammar-schools, with about 180 children.

The parishes of St. Marylebone (pop., in 1831, 122,206), St. Pancras (pop. 103,548), and Paddington (14,540), in

the Holborn division of Ossulston hundred, constitute the parliamentary borough of Marylebone. They are for the most part united to London. [LONDON.] The hamlets of Camden Town and Kentish Town, and part of the village of Highgate, are in St. Pancras parish. Camden Town consists of some streets of good houses; and Kentish Town of some rows of houses and detached villas. Camden Town is now rapidly increasing, and has greatly improved of late years, especially since the completion of the London and Birmingham Railroad. There is an Episcopal chapel at Camden Town, and one in Kentish Town, beside several dissenting meeting-houses. There is a veterinary college at Camden Town. The Regent's Canal passes between these two hamlets.

Hampstead is on high ground, 4 miles from Holborn Bars, in Holborn division of Ossulston hundred. The parish, which contains 2070 acres, with a population, in 1831, of 8588, was separated from that of Hendon in 1598. It contains the village of Hampstead and the hamlet of Kilburn. The village of Hampstead contains mineral springs, once in considerable repute. The salubrity of the air, and the pleasantness of the prospect which, from its elevated situation, it enjoys, have made it a favourite place of residence: on the hill, north-east of the village, is an extensive heath, on which are some large ponds, or reservoirs of water, used for supplying Camden Town and the adjacent parts with water. The church, which is of brick, was built about the middle of the last century. There are two proprietary Episcopal chapels, and several dissenting places of worship. The living is a perpetual curacy, of the clear yearly value of 887*l*. There were, in 1833, two infant-schools, with 159 children; three charity-schools (two attached to the Established Church, and one supported by Roman Catholics), with 287 children; nine other day-schools, with 155 children; seventeen boarding-schools, with 384 children; one day and Sunday school (at Kilburn), with 85 children; and five Sunday-schools, with 585 children.

Islington, one mile north of Hicks's Hall, on the great north road, is in the Finsbury division of Ossulston hundred, and included in the metropolitan parliamentary borough of Finsbury. The parish has an area of 3050 acres, with a population, in 1831, of 37,316. The principal street, under the designations of High Street, Upper Street, and Holloway, runs for several miles along the north road to the foot of Highgate Hill. Lower Street branches off from High Street, and runs towards Newington Green and Stoke Newington. The Liverpool Road forms a back road to Holloway: the new north road, and the new road from King's Cross to Holloway, have been laid out within the last twenty years. Highbury, Canonbury, Ball's Pond, and Holloway, are portions of the village, which comprehends a number of ranges of good houses. The New River passes through the parish, and the Regent's Canal is carried by a tunnel under the High Street, which is on an eminence, and under the New River. A considerable part of the parish is occupied as pasture-land by cow-keepers, who supply the metropolis with milk. There are some nursery grounds, and one or two manufactories, together with lime and coal wharfs, in the part adjacent to the Regent's Canal. The church is situated between Upper and Lower streets, and is of brick, with a tower of the same materials, surmounted by a stone spire of good design. There is a chapel-of-ease at Lower Holloway, a plain and rather heavy brick building, built A.D. 1814; and there are district churches at Upper Holloway (St. John's, a neat building, with a square embattled tower, crowned with pinnacles), Ball's Pond (St. Paul's, a structure of similar character to St. John's), in Cloudesley Square, near the back road (Trinity Church), and St. Peter's, the last erected. There are also several dissenting places of worship. At Islington is a college, belonging to the Church Missionary Society, for the education of young men designed for foreign missions; and at Highbury an academy for the education of young men for the ministry among the Independents. The Caledonian Asylum is a handsome building, on the road leading from King's Cross, St. Pancras, to Holloway. Canonbury Tower, a heavy square brick building, is a relic of Canonbury House, the former mansion of the priors of St. Bartholomew's Monastery in Smithfield, and has been the residence of Dr. Goldsmith, Chambers, author of the Cyclopædia, and other persons of literary note. The living of Islington is a vicarage, of the clear yearly value of 1155*l*., the perpetual curacies are of the following clear yearly

value:—Lower Holloway Chapel, 351*l.*; St. John's, Upper Holloway, 250*l.*; St. Paul's, Bull's Bond, 335*l.*; and Trinity, Cloudeley Square, 485*l.* Of the chapelry of St. Peter's there is no return. There were, in 1833, four infant-schools, with 578 children; thirty-eight boarding-schools, and sixty-one day-schools, among which were included three national schools, with 204 children; three other charity schools, connected with the Established Church, with 582 children; a Lancasterian school, with 160 girls; a school of industry for 35 girls, and three other charity schools, with 260 children. There are a proprietary school for 160 boys, and nine Sunday-schools, with 1648 children. In the British Orphan Asylum 43 children are maintained and educated, and in the Caledonian Asylum about 100. There is a Literary and Scientific Institution.

Hornsey is in the same hundred and division, north of Islington. The area of the parish is 2960 acres; the population, in 1831, was 4856. It contains the village of Hornsey, and the hamlets of Crouch End, Muswell Hill, and Stroud Green. Few villages near London have retained a more rural character than Hornsey. It lies in a valley out of the great thoroughfares; the New River passes close to it. The church, which is of stone, has been recently restored or rebuilt all but the tower, which is more ancient. There were, in 1833, two national schools at Hornsey, with 115 children. The living is a rectory, of the clear yearly value of 493*l.*, with a glebe-house.

Highgate is on high ground on the great north road, 4 miles from London. Part of the village is in the parish of St. Pancras, and part in Hornsey parish. The village, which comprises some good villas and other houses, is on the top of a hill. A new church has been lately built, and a new school-room for the endowed grammar-school, which was founded by Chief-Justice Cholmeley in the reign of Queen Elizabeth. The master has a good salary and a house. There are some almshouses at Highgate, and one or two dissenting places of worship. Some ponds at Highgate contribute to supply part of the northern suburbs of the metropolis with water.

In order to avoid the steep declivity at Highgate, a project was formed in 1809 for carrying the north road through a spacious arched tunnel. The work was commenced; but in 1812 the earth over the tunnel fell in, the plan of a tunnel was given up, and a road was cut through the hill. A road which crosses the north road is carried over it by means of an archway of brick and stone. An extensive cemetery has lately been formed at Highgate, on the slope of the hill just below the church: the grounds are well laid out, and the entrance gateway contains a chapel and other apartments. There are numerous catacombs in this cemetery. There were in Cholmeley's grammar-school, in 1833, 33 boys; in another endowed school were 26 girls; and in a national school, 98 boys. A room for a national school for 100 girls was building at the same time.

Hackney is 2 miles from Shoreditch church, on one of the branches of the Norfolk and Suffolk roads. The parish has an area of 3300 acres, with a population, in 1831, of 31,047. It contains the several villages or hamlets of Hackney, Homerton, Upper and Lower Clapton, Stamford Hill, Dalston, Shacklewell, the greater part of Kingsland, and a part of Stoke Newington. Hackney, properly so called, has one principal street, known as Mare Street and Church Street, and some other streets, containing many good houses, some of them of old date, for this was one of the earliest places of rural retirement to the wealthy merchants and traders of London. The church was rebuilt near the close of the last century; it is a large brick building devoid of external beauty, but its interior construction and arrangements have been the subject of much commendation. It has a stone tower of modern erection, but as this was insufficient to bear the bells, the tower of the former church has been allowed to remain in the churchyard, which is spacious and pleasantly laid out. South Hackney church, originally built as a chapel-of-ease, but since made a district church, has little architectural beauty. Homerton adjoins Hackney on the north-east, and consists of one street, half a mile long, leading down to the marshes of the Lea. It has a proprietary Episcopal chapel, and a college rebuilt a few years since for the education of Congregational ministers. Clapton lies north of Homerton, and Stamford Hill north of Clapton. There are at Clapton a neat iron bridge, called Lea Bridge, over the Lea, and a handsome building erected for the London Orphan Asylum. At Stamford Hill is an Episcopal

chapel, originally a proprietary chapel, but since purchased by subscription of the inhabitants and enlarged. Those parts of Kingsland and Newington which are in this parish are on the York road. On this road is the district church of West Hackney, a Doric edifice of good design. It has a large churchyard and a parsonage house. There is a small ancient chapel at Kingsland, partly in this parish, partly in Islington. Dalston and Shacklewell lie between Hackney proper, Kingsland, and Newington. There are several dissenting meeting-houses; and several ranges of almshouses in the parish; among the latter is 'the Retreat' for the Widows of twelve Independent or Baptist Ministers. Dyeing, calico printing, and some other manufacturing processes are carried on in the parish; and there are considerable brick fields. The Regent's Canal and the Lea navigation pass through the parish.

Hackney parish originally constituted one benefice; but it has lately been divided into four districts, which, with the clear yearly value of their benefices, are as follows:—Hackney Rectory (the mother church), 1082*l.*, with a glebe-house; South Hackney Rectory, 399*l.*; West Hackney Rectory, 464*l.*, with a glebe-house; Stamford Hill Chapelry, 165*l.* There were in the parish, in 1833, sixty-three day and boarding schools of all kinds, four day and Sunday schools, and ten Sunday-schools. Of these schools four were infant schools, supported chiefly by endowment or subscription, with 470 to 490 children; fifteen others were charity schools, including two national and two Lancasterian schools, the Cumberland Benevolent Institution, the London Orphan Asylum, and the boys' establishment of the Children's Friend Society, which is at Hackney Wick. There are two proprietary grammar-schools; one connected with the Church of England, the other open to all sects. The school-house of the former is a brick building at Clapton, with a Doric front and portico finished with cement in imitation of stone; that of the latter is near Hackney churchyard, and is of Gothic architecture.

Bow is on the other and main branch of the Norfolk and Suffolk roads, 2½ miles from Whitechapel church. The name of the parish is Stratford-le-Bow, but we have given the colloquial abbreviation in order to distinguish it from Stratford Langthorn, or colloquially Stratford, which is just across the Lea in Essex. Between Bow and Stratford is an ancient bridge over the Lea. Bow church is an ancient structure, chiefly in the early English style, but there are some portions of Norman architecture. A yearly fair, much resorted to by the Londoners, has been of late years suppressed. The parish, which has an area of 630 acres, with a population, in 1831, of 3371, was separated from that of Stepney in 1730. At the hamlet of Oldford, in the parish, are the East London waterworks. The living is a rectory, of the clear yearly value of 319*l.*, with a glebe-house. There were, in 1833, three dame-schools, with 48 children; three boarding-schools, with 88 children; five day-schools, two of them endowed, with 109 children, and three unendowed, with 42 children; and two Sunday-schools, with 244 children.

Bromley is adjacent to Bow. Distilling and calico printing are carried on, and many of the inhabitants are much engaged in the East and West India Docks, and in the adjacent dockyards in Limehouse and Stepney parishes. The church has some traces of Norman architecture: it was probably the chapel of a Benedictine nunnery once existing here, whose revenue at the suppression was 121*l.* 16*s.* 0*d.* gross, or 108*l.* 1*s.* 11*d.* clear. The parish has an area of 620 acres, with a population, in 1831, of 4846. The living of Bromley is a donative, of the clear yearly value of 190*l.* The parish had, in 1833, one infant school, with 20 children; an endowed day-school, with 17 boys; two national schools, with 195 children; one other day-school, with 12 children; and one Sunday-school, with 180 children.

Stepney and Limehouse are immediately adjacent to London on the east side. The parish of Stepney comprehends an area of 2130 acres, and is divided into the four hamlets of Mile-End Old Town, Mile-End New Town, Poplar Chapel (with Blackwall), and Ratchiff, having a population in all of 67,872. Limehouse parish is immediately adjacent to Stepney, and comprises 280 acres, with a population of 15,695. These two parishes comprehend the Isle of Dogs, and the adjacent districts extending northward to the road to Bow, on which road the hamlets of Mile-End are situated. Along this road, and along the Commercial Road, extending from London to Limehouse, as well as in the immediate

streets and squares, are several ranges of good houses. Stepney church is a spacious building of stone and flint, probably erected in the 14th century. A new church was erected in the parish in the year 1822. There is at Stepney a college or academy for the education of ministers among the Calvinistic or Particular Baptists. Along the Mile-End Road are several hospitals or almshouses; of which the principal are the Jews' hospital, Bancroft's almshouses, and those belonging to the Trinity House. Limehouse church is one of the fifty erected in the reign of Queen Anne. Poplar chapel is a neat structure, almost entirely rebuilt in the latter part of the last century. The East India Hospital, in connection with this chapel, contains a dwelling for a chaplain, and for the widows of officers and seamen in the Company's service.

These two parishes are chiefly inhabited by seafaring people, or by those engaged in the building or fitting out of vessels. They contain the East India Docks and the West India Docks, and the basin at the junction of the Regent's Canal with the Thames. There are ship-building yards and ropewalks, also manufactories for anchors and chain cables, sail-cloth, ships' blocks, &c. The Regent's Canal and a cut from the river Lea to the Thames cross this parish. A tramroad leads along the south side of the Commercial Road from the West India Docks to Whitechapel: and a railroad is to run from London to Blackwall.

The living of Stepney is a rectory, of the clear yearly value of 1190*l.*, with a glebe-house. There is a chapelry attached to the new church, of the clear yearly value of 218*l.* Poplar is a rectory, of the clear yearly value of 632*l.*, with a glebe-house. Limehouse is a rectory, of the clear yearly value of 714*l.*

The parish of Stepney was once much more extensive than at present: those of St. Paul, Shadwell; St. Mary, Whitechapel; St. John, Wapping; St. Mary, Stratford-le-Bow; Christchurch, Spitalfields; St. George's in the East; St. Ann's, Limehouse; and St. Matthew, Bethnal Green, have been formed by separation from it. Had the parish retained its former extent, the population in 1831 would have been 250,000.

Stepney and Limehouse parishes contained, in 1833, three infant schools, seventy-three day-schools, and sixteen Sunday-schools. Of the day-schools, the principal are, Bancroft's school, in which 100 boys are boarded, clothed, and instructed; the Jew's hospital, for the employment and education of youth, with 58 children; Stepney proprietary school, with 120 boys; an endowed free-school under the management of the Cooper's company, with 35 boys; and several national or other charity schools. There are several dissenting congregations.

The parishes described above, from Hackney inclusive, are in the Tower division of Ossulston hundred, which is comprehended in the new metropolitan parliamentary borough of the Tower Hamlets.

Divisions for Ecclesiastical and Legal Purposes.—This county is included in the diocese of London, and is divided between the archdeacons of London and Middlesex. The City of London within and without the walls (with the exception of thirteen parishes which are peculiars of the archbishopric of Canterbury, one parish which is a peculiar of the bishopric of London, and four parishes which are in the peculiar jurisdiction of the dean and chapter of St. Paul's), the parishes of St. James, Clerkenwell, St. Leonard, Shoreditch, and St. Mary, Islington, and the precincts of Portpool, Hoxton, Norton Folgate, and Goswell-street, constitute the archdeaconry of London. The rest of the county (with the exception of twelve parishes which are in the peculiar jurisdiction of the bishop of London, seven which are in the peculiar jurisdiction of the dean and chapter of St. Paul's, and two which are peculiars of the archbishop of Canterbury) is included in the archdeaconry of Middlesex. The number of parishes and chapelries in the county, when Newcourt drew up his account of the diocese, was as follows:—

In London:	
Under the archdeacon of London	92
Peculiars	18
In the rest of Middlesex.	
Under the archdeacon of London	3
Under the archdeacon of Middlesex	52
Peculiars	21
Total	186

Since Newcourt's time the number of ecclesiastical divisions and benefices has considerably increased, through the subdivision of the larger parishes near London, such as Stepney, Hackney, Islington, St. Pancras, and St. Marylebone.

The county is, in civil suits, within the immediate jurisdiction of the superior courts sitting in the metropolis. In criminal cases of the more important class it is within the jurisdiction of the Central Criminal Court, held in the Old Bailey in London. Sessions, at which lighter criminal offences are tried, are held at the Sessions-house, Clerkenwell, twelve times in the year, and at Guildhall, for the city of London, eight times in the year. Sessions are also held for the city of Westminster. The city is under the police jurisdiction of its own aldermen; other parts immediately round London have police-offices, with stipendiary magistrates. The parts more distant from London are under the county magistrates.

The shrievalty of Middlesex is united with that of London. Two sheriffs are annually chosen by the Livery of London in common hall. London has a body of police of its own: the suburbs are watched by the metropolitan police, a numerous body of men under the direction of two commissioners.

Fourteen members of parliament are returned from Middlesex, namely, two for the county, four for the city of London, two for the city of Westminster, and two each for the new metropolitan boroughs of Marylebone, Finsbury, and the Tower Hamlets. The borough of Marylebone comprehends the three parishes of St. Marylebone, St. Pancras, and Paddington; that of Finsbury, various parishes and liberties in the Finsbury division of Ossulston hundred; and that of the Tower Hamlets, the liberties of the Tower and the Tower division of Ossulston hundred.

History and Antiquities.—In the earliest period of authentic history this part of our island was comprehended in the domains of the Trinobantes, who occupied Essex. It was traversed by Cæsar in his second expedition into Britain (B.C. 54), after his successful attempt to cross the Thames at Coway Stakes near Chertsey. [BRITANNIA.] It fell under the Roman dominion in the time of Claudius, but was overrun by the Britons in the general revolt under Boadicea. [BOADICEA.] Londinium (London) was already a place of considerable trade, and the residence of many Romans. In the Roman division of the island the county was included in the province of Flavia Cæsariensis, and contained the stations of Londinium, Pontes (according to some), and Sulloniæ. Of Londinium [LONDON] nothing need here be said. Pontes has been variously fixed, at Colnbrook and at Old Windsor in Berks, and at Longford and Staines in Middlesex. Sulloniæ was at Brockley Hill, between Edgware and Elstree. There are, or were till lately, traces of Roman camps at Stanmore, in the fields near Islington, and at Shepperton, near the place where Cæsar crossed the Thames. The Roman Watling Street from Londinium ran through Sulloniæ to Verulamium (near St. Alban's). Ermine Street ran from Londinium northward by Stoke Newington to Enfield, and other roads led from Londinium by Pontes and across the Thames to the south-west parts of England, and across the Lea into Essex. Of this last the fragment of a stone causeway in the marshes of the Lea, between Hackney Wick and Old Ford, may be regarded as a remain. The Thames was known to the Romans by the names Tamesis and Jamissa. The Roman names of the Lea, the Colne, and the Brent, are not known.

Beside various Roman antiquities found in London, others have been discovered in various parts of the county. At Bentley near Stanmore fifty gold coins and several of silver and copper were found, together with two rings and a bracelet, all of gold. Coins, urns, or other Roman antiquities have been dug up at Hampstead, Shepperton, and Turnham Green near Brentford.

In the Saxon division of the island this county is generally considered to have been a part of the kingdom of the East Saxons; but we think this may be questioned. Sir F. Palgrave has shown that among the Saxon states there were more than seven or eight which were properly distinct from each other, although the weaker were commonly held in subjection by their more powerful neighbours. (*History of England (Anglo-Saxon Period)*, in the *Family Library*.) Of these petty kingdoms or states we consider Middlesex (the territory of the Middle-Saxons) to have been one; for we do not think the name would have been given had Middlesex been, according to the common opinion, only a frontier

district of the East-Saxon kingdom. It may have been governed occasionally by the kings of Essex,—it is known that these at least possessed many extensive rights in the city of London; but Essex was itself little more than a dependency of Kent, and never enjoyed a period of political independence. It favours our supposition that Middlesex was not a mere province or county of the East Saxons, to find that in the division of England under Alfred, while the county of Essex and part of Hertfordshire were included in the Danelagh, or Danish territory, London and the rest of Middlesex were placed under the alderman of Mercia. (Sir F. Palgrave, *Rise and Progress of the English Commonwealth*, vol. i., pt. i., pp. 116, 402; pt. ii., pp. cclxxxiii., cccv.) It is however to be observed that some early authorities make Middlesex a part of the Danelagh. (Sir F. Palgrave, *Ibid.*, pt. i., pp. 48, 572.)

In the wars which the West Saxon princes sustained with the Danes, London was repeatedly taken by that people. In the great struggle between Alfred and the Danish chieftain Hastings the citizens bore a distinguished part. In the reign of Athelstan, London became the occasional residence of the king. In A.D. 1013 London submitted to the Danes under Svein or Sweyne, Ethelred II., whom they had endeavoured to support, having fled. In the following year the citizens threw off the Danish yoke, and recalled Ethelred. In the reign of Edmund II. Ironside, London was besieged by the Danish king Canute, but the siege was raised, after continuing some time, on the approach of Edmund. A battle between the rival princes was fought the same year at Brentford, the issue of which enabled Canute to resume the siege of London, but with no better success. The subsequent death of Edmund however brought the whole island under the sway of Canute.

London, having become, under the later Saxon princes or under the Norman dynasty, the seat of government, was the scene of many events which belong not to the provincial but to the general history of the country. In A.D. 1189, at the coronation of Richard I., there was a dreadful massacre of the Jews by the populace at Westminster. In A.D. 1196 a great tumult arose in London, headed by William Fitz-Osborn, surnamed Longbeard. In A.D. 1212 London was much damaged by a great fire. In the civil wars of John the citizens took the side of freedom. The Great Charter was signed by that king close upon the border of the county, between Staines and Windsor. In the subsequent war against the king, the citizens supported the cause of the dauphin Louis, who was however ultimately shut up in London, and compelled to relinquish his attempt on the kingdom. In A.D. 1222 another tumult of the Londoners arose: it was however quelled, the ringleaders executed or otherwise severely punished, and the city severely mulcted. In A.D. 1232 another great fire happened. In the following years many struggles were maintained against the injustice and oppression of Henry III. by the citizens, who, on the breaking out of the civil war, A.D. 1264, eagerly joined the insurgent barons. They burned the palace of the King of the Romans at Isloworth, and a summer-house belonging to the king at Westminster. On the suppression of this insurrection, after the battle of Evesham (A.D. 1265), the citizens were compelled to purchase exemption from the loss of their privileges by heavy payments. Just before the breaking out of this insurrection there was a great massacre of the Jews in London. In the year 1267 the city was occupied by the earl of Gloucester, who repelled for a time the king's army. He was however obliged to submit.

In the civil wars of Edward II. the city was first threatened and then occupied by the insurgent barons, A.D. 1320. At a subsequent stage of the troubles, A.D. 1322, several of the supporters of the king, and his favourites, the two Despencers, were put to death by the populace. In the subsequent reign of Edward III. a considerable tumult was excited on occasion of Wicliffe being cited before a synod at St. Paul's. The duke of Lancaster and Lord Percy, earl-marshal, afterwards well known as the earl of Northumberland, supported Wicliffe, while the citizens supported the bishop of London, whom they supposed to be threatened by those nobles. This tumult had almost cost the city its municipal privileges, and led to the removal of the lord-mayor and aldermen, on the plea that they had not properly exerted themselves to put the citizens down.

The rising of the Commons under Wat Tyler, A.D. 1381, belongs to the history of England. In 1387 the earls of Warwick and Arundel and the duke of Gloucester assem-

bled a considerable force at Hornsey Wood, to oblige the king to put away his followers. In A.D. 1388 the same lords with their followers assembled a force and marched to London, into which, after some hesitation, they were admitted. In A.D. 1390 the citizens of London, having offended the king, were obliged to appease him by a gift of 10,000*l.* to prevent much heavier consequences. The alienation produced by the king's oppressive conduct induced the citizens early to declare for his rival Henry of Bolingbroke, afterwards Henry IV.

In the reign of Henry V., early in the year 1413, several Wicliffites were seized in St. Giles's Fields by the king in person, who came upon them with an armed force. Treasonable purposes were imputed to them, and a great number were put to death. In the reign of Henry VI., A.D. 1450, London was seized by the insurgents under Cade, who committed great excesses, but after a sharp struggle was driven out by the citizens. At the commencement of the war of the Roses, a meeting of the leaders on both sides was held at London, with a view to a reconciliation, and a compromise effected; but some tumults arising between their retinues, suspicions arose again, and each party prepared for war. In A.D. 1460 the Yorkists were admitted into the city, while the king's troops occupied the Tower, from which they fired on the city. The citizens however obliged the garrison to surrender. In the same year the king was brought captive to London, and a peace was effected, which was very soon broken. The queen was about to re-enter London, when the approach of the earl of March obliged her to retire. The earl was declared king by his army, the citizens, and the nobles of his party, first in St. John's Fields, Clerkenwell, and afterwards at Baynard's Castle, in London, A.D. 1461. He assumed the title of Edward IV. In the year 1465 Henry VI., who had been again taken, was brought prisoner to London, and confined in the Tower. In 1470 he was released by the earl of Warwick. During the troubles of this period, a band of plunderers committed great excesses, but were put down by the earl of Warwick and duke of Clarence, and the leaders immediately hanged. In 1471 the Yorkists recovered the city, and Warwick was defeated and slain in the battle of Barnet. An obelisk erected on the spot records the event.

Edward, immediately after his victory at Barnet, marched to London, and, after parading the captive Henry through the streets, quitted the capital to engage Margaret, Henry's queen, at Tewkesbury. In his absence, London was attacked by the Bastard of Fauconbridge, who, after several repulses, retired. Henry died in the Tower very soon after, and Edward died at Westminster, A.D. 1483. The murder of Edward V. and the usurpation of Richard III., the coronation of Henry VII., his marriage, and the coronation of his queen, at Westminster (A.D. 1483-87), took place in London. In the reign of Henry VII. Perkin Warbeck was set in the stocks in London, and, about a year after, executed at Tyburn, for attempting to escape from the Tower, where he had been confined.

London was the scene of many of those acts of cruelty that have stained the memory of Henry VIII., and which need not be here enumerated. In Wyatt's rebellion against Mary (A.D. 1554), the city was threatened by the rebels, who, after obtaining possession of Southwark, marched to Kingston, crossed the Thames, and marched through Brentford and Turnham Green to attack London. Wyatt was however repulsed and obliged to surrender. The execution of Lady Jane Grey and her husband followed; fifty of Wyatt's followers were hanged in different parts of the city, and Wyatt himself was beheaded soon after. At the time of the Armada, London raised a body of 10,000 men, and the rest of the county 1000 more, with a few light horse and lancers. The city also furnished twenty-nine ships and barks, and above 2000 men: and the merchant adventurers ten ships of war. In A.D. 1601 the city was disturbed by the tumult excited by the earl of Essex, who was taken, and, with many of his supporters, beheaded. In A.D. 1605 the well-known gunpowder plot was formed and detected.

The commencement of the civil troubles of Charles I. was marked by some disturbances at London, which was devoted to the parliamentary cause; and on the breaking out of the war, the passages about the city were fortified, and the trained bands raised. After the battle of Edge Hill, the earl of Essex returned to London; and the king pursued him as far as Brentford, which, after a sharp action,

he captured. On this, the trained bands and other forces under Essex marched to Turnham Green, but no battle was fought, and the king soon quitted the county. In A.D. 1643 the cities of London and Westminster with Southwark were surrounded by defensive works of great extent, which were demolished by order of parliament, about four years afterward. In 1645 the conferences for peace at Uxbridge were held. In 1648 a tumult arose in the city, and the rioters were not put down until after some bloodshed; and in 1649 Charles I. was beheaded.

In 1661, after the Restoration, London was again made the scene of tumult by the Fifth Monarchy-men under Venner. The great plague of London in 1665, and the great fire of 1666, are events well known; also the great agitation of the metropolis during the supposed discovery of the popish plot. The attempts upon the city charters and the severities inflicted upon some leading citizens in the closing years of Charles II. and in the reign of James II. are also well known.

In the year 1688 James II. formed a camp on Hounslow Heath; but his army, partaking of the national feeling, deserted him. In A.D. 1710 London was much agitated by the trial of Dr. Sacheverell. In the rebellion of 1745, a camp was formed on Finchley Common, and the city trained bands and county militia were kept in readiness to march. In 1780 London was the scene of destructive riots, occasioned by popular hatred to Catholicism. In 1815 there were some tumults on account of the corn-laws, and a few years afterwards on account of reform in parliament. Since then there has been no event in the history of the county of sufficient importance to be noticed here. (*Beauties of England and Wales; Ordnance Maps; Conybeare*

and Phillip's *Outlines of the Geology of England and Wales; Parliamentary Papers.*)

STATISTICS.

Population.—Middlesex, as containing the great metropolis of the United Kingdom, of course cannot be compared with any other county of England, the population in proportion to its surface being vastly greater; the population of the other part of the county not included in the metropolis is not a fourteenth of the whole. As an agricultural county Middlesex therefore ranks very low, being the 42nd, or the very lowest in the scale. Of 358,521 males twenty years of age and upwards, living in 1831, only 12,516 were engaged in agricultural pursuits, and 11,064 in manufactures or in making manufacturing machinery. In this latter number is not included that numerous class of workmen of the best kind in all descriptions of manufactures, who are employed in London for combining, fitting, and finishing all the commodities requisite for the consumption and vast commerce of the metropolis. Workmen so employed are classed and specified in the detail of trades and handicrafts to the amount of four hundred different kinds. Independent of these, the manufactures of Middlesex are not of importance. More than 5000 males twenty years of age and upwards are employed in the manufacture of silk at Bethnal Green and its neighbourhood. At and near Whitechapel 440 men are employed in sugar-refinery. At Limehouse, sail-cloths and chain-cables are made; crape and oiled leather at Enfield; copper-works exist at Harefield, and mustard-mills at Staines.

The following table contains a summary of the population, &c. of every hundred, as taken in 1831:—

HUNDREDS, CITIES, OR BOROUGHES.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Build- ing.	Unin- habited.	Families chiefly employed in Agri- culture.	Families chiefly employed in trade, manufac- tures, and handicraft.	All other Families not com- prised in the two preced- ing classes.	Males.	Females.	Total of Persons.	Males, twenty years of age.
Edmonton hundred	4,801	5,616	79	359	1585	1,620	2,411	12,969	13,961	26,930	6,242

Totals	180,493	314,039	3919	14,413	9882	173,822	130,335	631,410	726,920	1,358,330	358,521

The population of Middlesex, at each of the four following periods, was:—

	Males.	Females.	Total.	Increase per cent.
1801	373,655	444,474	818,129	..
1811	434,633	518,643	953,276	16.52
1821	533,573	610,958	1,144,531	20.06
1831	631,410	726,920	1,358,330	18.69

showing an increase between the first and last periods of 540,201, or about 67 per cent. on the whole population, being 10 per cent. more than the whole rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of—

	£.	s.	d.	
1801	were 349,200,	being	8 6	for each inhabitant.
1811	.. 502,967	"	10 6	"
1821	.. 582,055	"	10 2	"
1831	.. 681,567	"	10 0	"

The sum expended for the same purpose for the year ending March, 1838, was 383,076*l.*; and assuming that the population had increased at the same rate of progression as in the ten preceding years, the above sum gives an average of nearly 5*s.* for each inhabitant. This last average is below that for the whole of England and Wales.

The sum raised in this county for poor-rate, county-rate, and other local purposes, in the year ending 25th March, 1833, was 968,724*l.* 19*s.*, and was levied upon the various descriptions of property as follows:—

On land	£69,833 13 <i>s.</i>
Dwelling-houses	823,248 15
Mills, factories, &c.	57,352 2
Manorial profits, navigation, &c.	18,290 9
Total	£968,724 19

The amount expended was—

For the relief of the poor	£647,013 6s
In suits of law, removal of paupers, &c.	19,915 15
For other purposes	336,959 18

Total money expended 1,003,888 19

In the returns made up for subsequent years the descriptions of property assessed are not specified. In the years 1834, 1835, 1836, 1837, and 1838, there were raised 939,890*l.* 6*s.*, 754,660*l.* 17*s.*, 641,378*l.* 15*s.* (not stated in tables for 1837), and 573,106*l.* respectively; and the expenditure of each year was as follows:—

	1834.	1835.	1836.	1837.	1838.
For the relief of the poor	582,412	493,041 16	408,027	260,981	383,076
In suits of law, removal of paupers, &c.	20,427	14,685 3	12,335	9,354	7,715
Payments towards the county-rate	313,678	64,588 10	66,154	not given.	71,580
For all other purposes		187,044 18	174,174	173,460	165,359
Total money expended	£916,517	749,360 7	660,690	513,795	627,730

The saving effected on the sum expended in 1838, as compared with that expended in 1834, was therefore 288,787*l.* 15*s.*, or about 31½ per cent.; and the saving effected on the sum expended for the relief of the poor was 199,336*l.*, or rather more than 34 per cent. as compared with the expenditure in 1834.

The number of turnpike trusts in Middlesex, as ascertained in 1835, under the acts 3rd and 4th Wm. IV., chap. 80, was 7; the number of miles of road under their charge was 158. The annual income arising from tolls and parish compositions in lieu of statute duty was (in 1835) 96,744*l.* 14*s.*, and the annual expenditure in the same year was as follows:—

	£.	s.	d.
Manual labour	14,169	19	0
Team labour and carriage of materials	12,741	11	0
Materials for surface repairs	36,207	13	0
Land purchased	50	10	0
Damages done in obtaining materials	47	14	0
Tradesmen's bills	4,992	4	0
Salaries of treasurer, clerk, and surveyor	4,030	17	0
Law charges	1,505	2	0
Interest of debt	5,806	7	0
Improvements	4,506	19	0
Debts paid off	9,100	0	0
Incidental expenses	8,313	12	0
Estimated value of statute duty performed	26	5	0

Total expenditure £101,498 13 0

The county expenditure in 1834, exclusive of that for the relief of the poor, was 69,373*l.* 18*s.*, disbursed as follows:—

	£.	s.	d.
Bridges, building, repairs, &c.	2,831	17	0
Gaols, houses of correction, &c., and maintaining prisoners, &c.	22,819	7	0
Shire-halls and courts of justice, building, repairing, &c.	1,943	4	0
Prosecutions	6,674	4	0
Clerk of the peace	1,782	9	0
Lunatic Asylums	1,631	4	0
Vagrants, apprehending and conveying	1,105	19	0
Constables, high and special	120	19	0
Coroner	1,534	12	0
Debt, payment of, principal and interest	26,190	0	0
Miscellaneous	2,740	3	0

Total expenditure 69,373 18 0

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were respectively 16,692, 19,883, and 24,965; making an average of 2387 annually in the first period, of 2840 in the second period, and of 3566 in the third period. The numbers of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect of whom any costs were paid out of the county rates, were 202, 224, and 1180 respectively. Among the persons charged with offences, there were committed for—

	1831.	1832.	1833.
Felonies	128	152	1094
Misdemeanors	74	72	86

P. C., No. 937.

The total number of committals in each of the same years was 1707, 1701, and 2977 respectively.

	1831.	1832.	1833.
The number convicted was	293	342	1368
Acquitted	109	105	239
Discharged by proclamation	1305	1254	1370

In 1838 there were 3488 persons charged with crimes at the assizes and sessions in Middlesex. Of these 329 were charged with offences against the person, 204 of which were common assaults; 150 were charged with offences against property committed with violence, and 2740 with offences against property committed without violence. Of the remaining number 4 were charged with arson; 143 with forgery, and with uttering counterfeit coin; 11 with perjury, 27 for riot, and 84 for various other misdemeanors.

Of the whole number committed, 2578 were convicted, 625 were acquitted, 29 were not prosecuted, no bill was found against 246, and 10 were found insane. Of those convicted, 4 were sentenced to death, not one of whom was executed; the sentences against them being commuted to transportation for various periods: of the remaining offenders, 22 were transported for life, 2 for fifteen years, 86 for ten, and 707 for seven years. Sentence of imprisonment for 3 years, or above 2 years, was passed on 3; 70 were imprisoned for 2 years, or above 1 year; 193 for 1 year, or above 6 months; and 1365 for 6 months or under: 126 were fined. Of the whole number of offenders, 2663 were males and 825 females; 919 could neither read nor write, 1818 could read and write imperfectly, 682 could read and write well, 7 had received superior instruction, and the degree of instruction of the remaining 62 could not be ascertained.

The number of persons qualified to vote for the county members, and registered, in 1837, was 12,817. Of these, 9485 were freeholders, 1065 leaseholders, 975 copyholders, and 1292 occupying tenants, being one in 106 of the whole population, and one in 28 of the male population twenty years and upwards, as taken in 1831. The number of electors that voted at that election was 9214, viz. 6739 freeholders, 730 copyholders, 809 leaseholders, and 936 occupying tenants.

This county contains 27 savings' banks; the number of depositors and amount of deposits on the 20th of November, in each of the following years, were as under:—

	1832.	1833.	1834.	1835.
Number of depositors	50,827	56,709	62,543	68,237
Amount of deposits	£1,393,360	£1,553,930	£1,705,308	£1,844,350

The various sums placed in the savings' banks in 1836, 1837, and 1838, were distributed as under:—

	1836.	1837.	1838.
	Depositors. Deposits.	Depositors. Deposits.	Depositors. Deposits.
Not exceeding £20	43,134 £970,806	47,200 £288,362	52,742 £331,334
" 50	19,895 612,603	21,627 662,401	24,075 728,062
" 100	3,202 565,050	8,830 609,370	9,685 666,125
" 150	2,502 301,677	2,689 323,618	3,140 377,648
" 200	1,261 214,280	1,316 224,555	1,558 266,065
Above 200	201 49,757	179 44,994	179 45,005
	75,195 2,014,173	81,841 2,153,300	91,379 2,424,239

Education.—The following is an abstract taken from the Education Returns laid before parliament in 1833:—

	Schools.	Scholars.	Total.
Infant schools	109		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		3,065	
Females		2,411	
Sex not specified		3,226	
			8,732
Daily schools	2,152		
Number of children at such schools; ages from 4 to 14 years:—			
Males		49,991	
Females		34,446	
Sex not specified		8,051	
			92,488
Schools	2,261		
Total of children under daily instruction			101,220

Vol. XV.—2 D

	Schools.	Scholars.	Total.
Sunday-schools	329		
Number of children at such schools ; ages from 5 to 15 years :—			
Males		23,440	
Females		23,225	
Sex not specified		5,456	
		—	52,121

If we assume that the population between the ages of 2 and 15 years had increased in the same proportion as the whole population since 1821, and that the whole population had increased from 1831 to 1833 in the same ratio as during the ten years preceding 1831, we find that the number of children between the ages of 2 and 15 residing in Middlesex in 1833 was 469,563. Only two Sunday-schools are returned from places where no other schools exist, wherefore it may be said that all Sunday-school children in this county have opportunity of resorting to other schools also; but in what number or in what proportion duplicate entry of the same children is thus produced, must remain uncertain. Seventy-five schools, containing 11,529 children, which are both daily and Sunday schools, are returned from various places, and duplicate entry is therefore known to have been thus far created. At a few of the schools there are some scholars twenty years of age. Making allowance therefore for these two causes, for uncertainty, it appears that not more than one-quarter of the children between the ages of 2 and 15 are under instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and pay- ment from scholars.	
	Schls.	Scho- lars.	Schls.	Scho- lars.	Schls.	Scho- lars.	Schls.	Scho- lars.
Infant Schools	3	530	23	2,610	31	603	47	4,989
Daily Schools	107	9,266	184	23,927	1746	43,715	115	15,550
Sunday Schools	3	311	290	46,878			36	4,932
Total.	113	10,107	502	73,415	1777	44,348	198	25,471

The schools established by Dissenters, included in the above statements, are—

	Scholars.
Infant schools	7, containing 577
Daily schools	103 . 9,170
Sunday-schools	150 . 27,689

The schools established since 1818 are—

	Scholars.
Infant and other daily schools	1,719, containing 67,158
Sunday-schools	219 . 37,484

Two hundred and thirty-eight boarding-schools are included in the number of daily schools given above. No school in this county appears to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by dissenters, with whom are here included Wesleyan Methodists, Roman Catholics, and Jews. Lending libraries of books are attached to 164 schools in Middlesex.

MIDDLETON, THOMAS, a celebrated dramatist in the reigns of Elizabeth, James I., and Charles I., the events of whose life are even less known than those of most of his contemporaries: indeed not a single circumstance is recorded respecting him by a writer of his own time; and excepting the fact that he was appointed chronologer to the city of London in 1620, mentioned by Oldys in his MS. notes to Langbaine, we are absolutely ignorant of his biography. He is supposed by Malone to have died in 1626.

The plays written by Middleton are very numerous. three of them, 'A Mad World, my Masters,' the 'Mayor of Queenborough,' and the 'Roaring Girl,' are in Dodsley's Collection, and the rest can only be procured separately. The 'Roaring Girl' is extremely valuable, as giving a picture of London manners in the author's time; it is interspersed with much of the slang which we find in Beaumont and Fletcher's 'Beggar's Bush,' and the heroine is a real character, the notorious Moll Cutpurse, who was introduced by Nat. Field, a contemporary dramatist, in his piece, 'Amends for Ladies.' A play of Middleton's, called 'The Witch,' has gained celebrity from the circumstance that Shakspeare is supposed by some to have borrowed from it his incantations in 'Macbeth.' Besides the numerous pieces by himself alone, Middleton assisted Rowley in 'The Changeling,' 'The Spanish Gypsy,' and 'The Fair Quarrel,' and both him and Massinger in 'The Old Law'; he also

joined with Fletcher and Jonson in the composition of 'The Widow,' which is printed in Dodsley.

Middleton does not hold the first rank among the dramatists of his day. His two best known plays, 'A Mad World, my Masters,' and the 'Roaring Girl,' are chiefly marked by a bustling variety of plot, a succession of incidents somewhat extravagant, and a familiarity with low life. He was however valued by his contemporaries, as is proved by his being chosen to assist such men as Jonson and Massinger.

MIDDLETON, SIR HUGH, was the sixth son of Richard Middleton, Esq., who was governor of Denbigh Castle, in Denbighshire, during the reigns of Edward VI., Mary, and Elizabeth. The name was variously spelt in those times, Mydelton, Myddleton, or Midleton. The date of Hugh Middleton's birth is unknown, and nothing has been recorded of the course of his life previous to his great undertaking of forming the New River and bringing it to London, except that he was a goldsmith in London, and had realised a very large property by the working of some copper-mines in Wales; and the decisive boldness with which he engaged in so vast and difficult an enterprise was probably the result of his having, in the conducting of his own mining speculations, acquired that practical knowledge of levelling, draining, embanking, and all the diversity of skill and fertility of resources necessary for the management of such a work. [MINING.]

Towards the latter end of the reign of Elizabeth, the metropolis of England being very inadequately supplied with water, the citizens of London obtained an act of parliament which gave them the legal authority to bring water from any part of Middlesex or Hertfordshire. For a considerable time however nothing was done, till, on the 28th of March, 1606, Hugh Middleton, 'citizen and goldsmith,' offered to bring to London a sufficient supply of pure water at his own cost. His offer was accepted; the citizens made over to him all the powers and privileges conferred by the act; and four years were allowed to complete the work. Having made the necessary surveys and preparations, and fixed on the Chadwell and Amwell springs, near Ware, in Hertfordshire, as the sources out of which his New River was to be formed, on the 20th of April, 1608, he commenced a work which, considering the imperfect mechanical resources of that age, may justly be regarded as stupendous. The distance from London by the road is about twenty miles, but the whole course of the river is thirty-seven miles. The ground through which it was to be brought presented much difficulty from its diversity of bottom as well as of level. In some places it was necessary to cut a channel thirty or forty feet deep; in others, to conduct the stream over valleys in troughs on wooden supports upwards of twenty feet high; and a vast number of bridges were to be constructed for the accommodation of those through whose grounds the stream was carried. These difficulties, together with others arising from the opposition of interested and influential persons, rendered it impossible to complete the work in the stipulated four years, and Middleton applied for an extension of the time, which was granted. Soon afterwards however he found that his large property was entirely exhausted. He applied to his fellow-citizens for assistance, but he applied in vain. He then solicited the king, James I., who, on the 2nd of May, 1612, entered into a covenant with Middleton, by which he engaged to pay half the expense, past and future, on condition of being entitled to half the property. The work was now pushed forward with increased vigour, and on the 29th of September, 1613, five years and five months from the commencement of the undertaking, and the day on which Sir Thomas Middleton, Hugh's brother, was elected lord-mayor for the ensuing year, the stream was admitted into the reservoir prepared for it at Sadler's Wells, near Pentonville. In the 'Biographia Britannica' an interesting account is given of the ceremony on this occasion, which was attended by the lord-mayor then in office, the aldermen, the recorder, and many of the principal citizens. The whole expense of the work was about 500,000*l.* Middleton was knighted soon afterwards, but for eighteen years after the completion of his undertaking no dividend was returned, and in the nineteenth year the first dividend only amounted to 1*l.* 1*s.* 1*d.* on each share.

Sir Hugh Middleton was compelled to sell his shares, and to support himself by the profession of what is now called a civil engineer. On the 19th of October, 1622, he was created a baronet for the following reasons (the king by special warrant kindly excusing him from the payment of

the usual fine of 1095*l.*):—'1. For bringing to the city of London with excessive charge and greater difficulty a new cut or river of fresh water, to the great benefit and inestimable preservation thereof. 2. For gaining a very great and spacious quantity of land in Brading Haven in the Isle of Wight, out of the bowelles of the sea; and with banks and pylos and most strange defensible and chargeable mountains, fortifying the same against the violence and fury of the waves. 3. For finding out, with a fortunate and prosperous skill, exceeding industry, and no small charge, in the county of Cardigan, a royal and rich mine, from whence he hath extracted many silver plates, which have been coined in the Tower of London for current money of England. W. Camden, Clarenceux, November 1, 1622.' (*Harleian Misc.*) On the 18th of November, 1636, Charles I. granted to Sir Hugh the whole of King James's shares for an annual rent of 500*l.* Middleton is supposed to have died soon afterwards, leaving a numerous family in very indifferent circumstances.

The springs near Ware are beautifully clear and very copious; but, a great many years ago, the supply having been found inadequate to the demands of the increased population, the New River Company entered into an agreement with the Commissioners of the Lea River to take a portion of the Lea at Ware, which was conveyed at first through pipes, but some years afterwards it was agreed that there should be an opening made of six feet by two, which is called the Marble Gauge. The Amwell spring now runs into the Lea River, and has done so for a great number of years; but an ample supply having been obtained from the Lea, it is presumed that the New River Company made no objection to the Amwell spring being turned from its original course; the time however when it was done is not certainly known.

The fall of the New River is three feet per mile, which gives a velocity of about two miles an hour. The average width is about 21 feet, and the average depth about four feet in the centre; so that, taking it at half the depth, there is a section of forty-two square feet flowing to London at the rate of two miles an hour. At the Sluice, near Highbury, the river is dammed back to the height of twenty inches, at Enfield to two feet four inches, and there are three or four more similar interruptions for the purpose of checking the current. This has been done because the Commissioners of the Lea complained that the New River Company, by enlarging the bridges and taking off the bends of the river to bring it more speedily to London, took more water than they were legally entitled to. They could take one-third more if they had the right; but not having enough, they have erected a steam-engine at Broken Wharf, which pumps up an additional supply from the Thames, pouring it directly into the main-pipe. To get rid of the engine at Broken Wharf the New River Company have tried, but hitherto, we believe, in vain, to get an act of parliament granting the right to take an additional supply from the Lea at Tottenham, and with that view have purchased Tottenham mill, together with fifty acres of ground, which they could convert into a reservoir.

The New River, especially in winter, is occasionally rendered dirty by drainage from the land and villages along its course, and the company have been at great expense to purify the water before it is delivered to the inhabitants of London. For this purpose two settling reservoirs were formed at Stoke Newington in 1832, under the direction of Mr. Mylne, the Company's engineer. The water covers an area of thirty-eight acres, more than twenty feet deep in some places, and twelve feet on the average. A part or the whole of the New River can be turned into the upper reservoir, where it settles, and is then drawn off by a steam-engine, and poured into the lower reservoir, where another settlement takes place, and the water is then turned again into the channel of the New River. Bathing in the New River is now entirely prohibited; and men called walksmen mow the bed of the river every week to keep down the growth of weeds, which are stopped by gratings seven miles from each other, where the weeds are taken out.

The capital of the Company has been stated by themselves to be 1,038,426*l.*, divided into 72 shares, or 14,426*l.* per share.

We subjoin a short table founded upon a 'Report on the Metropolis Water,' printed by order of the House of Commons, in August, 1834; by which it will be seen that the New River furnishes almost as much as the other seven companies united, supplying 70,145 houses (including large

manufactories, breweries, &c.) with 16,905,000 gallons of water daily, at the average rate of 241 gallons per day to each house, at an average charge of less than 1*d.* per day.

	Houses.	Gallons daily to each house.	Total gallons per day.	Charge yearly to each house.

(Stow's *Survey of the City of London*; *Biographia Britannica*; Nelson's *History of Islington*; *Report on the Metropolis Water*, 1834.)

MIDDLETON, CONYERS, born August 2nd or December 27th, 1683, was the son of William Middleton, rector of Hinderwell, near Whitby in Yorkshire. At the age of seventeen he was sent to Trinity College, Cambridge, of which college he was two years afterwards chosen a scholar. He took his degree of B.A. in 1702, and was shortly after ordained deacon. In 1706 he was elected a fellow of Trinity College; and in 1708, joined with other fellows of his college in a petition to the bishop of Ely, as the visitor of the college, against Bentley the master. Middleton, who was then a young man, did not take a prominent part in this proceeding; but the feelings of hostility to the master originated by these disputes sank deep into his mind, and made him subsequently the most determined and dangerous of his enemies.

Middleton married soon afterwards, and resided for a short time in the Isle of Ely on a small living in the gift of his wife, but the unhealthiness of the situation induced him to return to Cambridge at the end of a year.

When George I. visited the university of Cambridge in 1717, Middleton, with several others, was created Doctor of Divinity; but Bentley, who was Regius Professor of Divinity, refused to confer the degree unless a fee of four guineas was given to him in addition to the broad piece which was the ancient and customary compliment on this occasion. This demand was resisted by Middleton, who however at last consented to pay it, on condition that the money should be restored if it should be determined that it was an illegal demand. Middleton sued Bentley for it in the vice-chancellor's court; and Bentley, refusing to pay the money or to acknowledge the jurisdiction of the court, was deprived of all his degrees by a grace of the senate, October 17, 1718. [BENTLEY.] As Bentley was a firm supporter of the Whig ministry then in power, it was feared that a commission might be issued by the crown to inquire into the state of the university; and Middleton, to justify himself and his friends, accordingly published 'A full and impartial Account of all the late Proceedings in the University of Cambridge against Dr. Bentley,' which, says Dr. Monk, 'was the first published specimen of a style, which, for elegance, purity, and ease, yields to none in the whole compass of the English language. The acrimonious and resentful feeling which prompted every line is in some measure disguised by the pleasing language, the harmony of the periods, and the vein of scholarship, which enliven the whole tract.' (*Life of Bentley*, p. 388.)

A few months afterwards, Middleton published 'A Second Part of the full and impartial Account of all the late Proceedings, &c.,' and also 'A true Account of the present State of Trinity College, in Cambridge, under the oppressive Government of their Master, R. Bentley, late D.D.' In the latter pamphlet Middleton had declared 'that the fellows of Trinity College had not been able to find any proper court in England which would receive their complaints;' and Bentley perceiving that his adversary had been guilty of an expression which might be considered as a libel upon the whole administration of justice in the kingdom, brought an action against him in the Court of King's Bench, in which the jury returned a verdict of guilty. The court however was unwilling to pronounce sentence, and the matter eventually dropped by Middleton's begging pardon of Bentley and consenting to pay all the expenses of the action, which must have been considerable, since the share of the expenses of the prosecution not allowed by the

master of the court, and paid by Trinity College, amounted to 150*l*.

While this matter was pending, Bentley published Proposals for a new edition of the Greek Testament, with a specimen of the intended work. The proposals and specimen were drawn up by candle-light one evening, according to Bentley's own confession; and the whole sheet bore marks of precipitation and haste. Middleton eagerly availed himself of the opportunity which the carelessness of his great enemy had afforded him, and accordingly published a severe critique upon it, in a pamphlet entitled 'Remarks, paragraph by paragraph, upon the Proposals lately published by R. Bentley for a new edition of the Greek Testament,' and followed up his attack by 'Some further Remarks' a few weeks afterwards. Although Middleton professed, in the commencement of the pamphlet, that 'his remarks were not drawn from him by personal spleen or envy to the author of the Proposals, but by a serious conviction that he had neither talents nor materials proper for the work he had undertaken, and that religion was much more likely to receive detriment than service from it,' he nevertheless condescended to the lowest abuse against his antagonist; but it must be allowed that in this respect he was hardly a match for the master of Trinity.

As Middleton had been put to great expense and trouble by his recent prosecution, his friends in the university, regarding him as a sufferer in a public cause, resolved to bestow some public mark of distinction upon him, and accordingly established a new office of principal librarian, to which Middleton was elected notwithstanding the violent opposition of the other party. Shortly after his election, he published a plan for arranging the university library, which was entitled '*Bibliothecæ Cantabrigiæ Ordinandæ Methodus quædam*,' 1723; in the dedication of which to the vice-chancellor he expressed himself in a manner which appeared to call in question the jurisdiction of the Court of King's Bench; for which he was again prosecuted by Bentley, and condemned to pay a fine of 50*l*.

Having lost his wife shortly after this, he travelled on the Continent, and spent some months in Rome in 1724. On his return to England, he renewed his suit against Bentley for the recovery of the four guineas, who at length paid the money to Middleton in 1725. In 1726 he published a short treatise '*De Medicorum apud veteres Romanos degentium Conditione Dissertatio; qua &c. servilem atque ignobilem eam fuisse ostenditur*,' which was considered an insult upon the whole medical profession. Several pamphlets were published in answer to it, to which Middleton replied in the following year.

In 1729 Middleton published his celebrated 'Letter from Rome,' in which he attempted to show that 'the religion of the present Romans was derived from that of their heathen ancestors,' and that in particular the rites, ceremonies, dresses of the priests, &c. in the Roman Catholic church were taken from the pagan religion. This work was received with the greatest favour by the learned, and went through four editions in the author's life-time; but the free manner in which he attacked the miracles of the Roman Catholic church gave offence to many divines of his own communion, who suspected and maintained that the author had as little respect for the miracles of the apostles as for those of the Roman Catholic saints. This suspicion was confirmed by his next publication in 1731, which was a letter to Dr. Waterland, containing some remarks on Waterland's reply to Tindal's attack upon revealed religion, in a work written by the latter, which was entitled 'Christianity as old as the Creation.' This letter, which was first published anonymously, but was soon known to be written by Middleton, gave the greatest offence to the clergy. Pearce, bishop of Rochester, replied to it; and so strong was the feeling against Middleton, that he was nearly deprived of his degrees, and nearly degraded from his office of public librarian. Finding it necessary to make an explicit avowal of his sentiments with regard to religion, Middleton published, in 1732, 'Some Remarks on a Reply to the Defence of the Letter to Dr. Waterland, wherein the Author's Sentiments as to all the principal points in dispute are fully and clearly explained,' in which he expressly asserted his belief in Christianity, and disclaimed all intention of attacking the evidences of revealed religion. It must however be admitted that Middleton had spoken of the Scriptures in a manner that was calculated to give just cause of offence; and there is abundance of evidence

in his writings to prove that he regarded Christianity in scarcely any other light than a republication of the law of nature, and that he endeavoured, like a certain class of modern divines in Germany, to reduce as far as possible everything supernatural in the Bible to mere natural phenomena. He expressly maintained that there were contradictions in the four evangelists, which could not be reconciled (*Reflections on the Variations found in the four Evangelists*); he accused Matthew 'of wilfully suppressing or negligently omitting three successive descents from father to son in the first chapter of his Gospel' (*Works*, vol. ii., p. 24, 4to. ed.); he asserted that the apostles were sometimes mistaken in their applications of prophecies relating to Christ (*Works*, vol. ii., p. 59); he considered the 'story of the fall of man as a fable or allegory' (*Works*, vol. ii., p. 131); and with respect to the prophecy given at the fall, that the seed of the woman should bruise the serpent's head, he did not hesitate to declare, in another part of his works (vol. iii., p. 183), 'that men who inquire into things will meet with many absurdities which reason must wink at, and many incredibilities which faith must digest, before they can admit the authority of this prophecy upon the evidence of this historical narration.' Such being the opinions of Middleton (and passages of a similar nature might be multiplied to almost any extent from his works), it cannot excite surprise that he should have been regarded by his brethren with suspicion, and have been looked upon, notwithstanding his assertions to the contrary, as a disbeliever in the fundamental doctrines of Christianity.

While these discussions were going on, Middleton was appointed to the professorship of natural history, which had been recently founded by Dr. Woodward, which appointment he resigned in 1734, and soon after married again. In the following year he published 'A Dissertation concerning the Origin of Printing in England,' showing that it was first introduced and practised by our countryman William Caxton at Westminster, and not, as is commonly supposed, by a foreign printer at Oxford. In 1741 he published by subscription his most celebrated work, 'The History of the Life of M. Tullius Cicero,' Lond., 2 vols. 4to. There were 3000 subscribers to this work, and the profits arising from its sale were so considerable, as to enable Middleton to purchase a small estate at Hildersham, six miles from Cambridge, where he chiefly resided during the remainder of his life. Middleton's 'Life of Cicero' is written, like all his other works, in a pleasing and perspicuous style; but the strong bias of the author in favour of his hero has frequently led him to become the panegyrist of very questionable actions, and even to misrepresent, perhaps not intentionally, those events which did not reflect credit on the character of his favourite. [CICERO, p. 158.] Dr. Parr, in a preface to a republication of Bellendenus, entitled 'De Statu,' asserts that Middleton, in his 'Life of Cicero,' borrowed very largely from a work of Bellendenus on the character, literary merits, and philosophical opinions of Cicero, which is entitled '*De Tribus Luminibus Romanorum*.'

Two years afterwards, Middleton published a translation of Cicero's letters to Brutus, and of Brutus's to Cicero, with the Latin text, and a prefatory dissertation, in which he defended the authenticity of the epistles against the objections of Tunstall, who maintained that they were the composition of some sophist. The arguments of Middleton were combated by Markland in his 'Remarks on the Epistles of Cicero to Brutus, and of Brutus to Cicero, in a letter to a friend.' [MARKLAND.]

In 1745 he published '*Germana quædam Antiquitatis eruditæ Monumenta*,' &c., in which he gave an account of the various specimens of antient art which he had collected during his residence at Rome. Two years afterwards he published his 'Treatise on the Roman Senate,' in which he maintained that all vacancies in the senate were filled up by the people; and in the same year he published 'An Introductory Discourse to a larger work, designed hereafter to be published, concerning the Miraculous Powers which are supposed to have subsisted in the Christian Church from the earliest ages,' which was followed in 1749 by 'A Free Inquiry into the Miraculous Powers,' &c. This work gave even more offence than his letter to Dr. Waterland; it was attacked by Dodwell, Church, and Chapman, and was generally condemned by the clergy as tending to destroy the authority of miracles in general. Middleton however disclaimed all such intention; and it must be allowed, that whatever may have been his private opinions, he does

not in this work advance anything which could fairly be construed into an attack upon revealed religion; perhaps the former controversy had made him more cautious. The object of the 'Free Inquiry' was to place the divines of his own church in the awkward predicament of either denying the authority of the fathers altogether, or else of admitting the truth of the leading doctrines of the Roman Catholic Church, which he maintains to be satisfactorily established by the testimony and miracles of the early fathers. Edward Gibbon, who was then a young man at Oxford, chose the latter alternative, and went over to the Roman Catholic Church, sooner than abandon the authority of the fathers. [GIBBON.]

In 1750 Middleton published 'An Examination of the Bishop of London's (Dr. Sherlock) Discourses concerning the Use and Intent of Prophecy,' in which he maintained that the use of prophecy, as it was taught and practised by Christ and his Apostles, was drawn entirely from single and separate predictions, gathered by them from the books of the law and the prophets, and applied, independently of each other to establish the Messiahship of Jesus, and that there was no foundation for Dr. Sherlock's argument that the prophecies of each age were intimately connected with each other and with those of the preceding age, and that the whole formed one connected series from the time of the antediluvians to the prophecies of Malachi.

Middleton died at Hildersham on the 28th of July, 1750. He accepted, shortly before his death, a small living from Sir John Frederick. His subscription to the thirty-nine articles and the canons of the church on that occasion was represented by his enemies, but whether justly or not it is difficult to say, as hypocritical and insincere.

The works of Middleton, with the exception of his 'Life of Cicero,' were collected and published after his death in four volumes, 4to. 1752, and subsequently in five volumes, 8vo. Several treatises appeared in this collection which had not been published before, of which the most important are—'A Preface to an Intended Answer to all the Objections made against the Free Inquiry;' 'Some cursory Reflections on the Dispute or Dissension which happened at Antioch between Peter and Paul;' 'Reflections on the Variations or Inconsistencies which are found among the Four Evangelists;' 'An Essay on the Gift of Tongues;' 'Some Short Remarks on a Story told by the Antients concerning St. John the Evangelist and Cerinthus the Heretic;' and 'An Essay on the Allegorical and Litteral Interpretation of the Fall of Man.'

MIDDLETON, THOMAS FANSHAW, D.D., the first English bishop of Calcutta, was the only son of the Rev. Thomas Middleton, rector of Redleston, in Derbyshire, and was born at that village on the 26th of January, 1769. In 1779 he was admitted into Christ's Hospital, London, and from thence he proceeded to Pembroke Hall, Cambridge, where he took his degree of B.A., with honours, in Jan., 1792. In the following March he received ordination, and entered upon the curacy of Gainsborough, in Lincolnshire. Here he edited a periodical work, entitled the 'Country Spectator,' which continued to appear for about seven months, and most of the papers in which were written by Mr. Middleton himself. In 1794 he became tutor to the two sons of Dr. John Pretyman, archdeacon of Lincoln, and brother of the bishop. In consequence of this appointment he removed, first to Lincoln, and afterwards to Norwich, where he became curate of St. Peter's Mancroft in 1799, having already, in 1795, been presented by Dr. Pretyman to the rectory of Tansor, in Northamptonshire. In 1797 he married Elizabeth, the eldest daughter of John Maddison, Esq., of Gainsborough. This lady not only brought him a great increase of domestic happiness, but also assisted him in his literary labours, by transcribing all his manuscripts for the press. In 1802 Dr. Pretyman presented him to the rectory of Bytham, in Lincolnshire. About this time he wrote his chief work, 'The Doctrine of the Greek Article, applied to the criticism and illustration of the New Testament,' which he published in 1808, with a dedication to Dr. Pretyman. In the same year he took his degree of D.D. at Cambridge, and removed to his living at Tansor, where he discharged his duties in such a manner as to gain the affection and esteem of his people. In 1809 he was appointed by Bishop Pretyman to a stall in the cathedral of Lincoln, and in 1812 to the archdeaconry of Huntingdon. In 1811 he resigned his two livings for the vicarage of St. Pancras, Middlesex, and the rectory of Rot-

tenham, in Hertfordshire. He fixed his residence at St. Pancras, and made the acquaintance of several dignitaries of the church and other distinguished individuals.

About this time a provision was inserted in the Act for the renewal of the East India Company's Charter, enabling the crown to constitute a bishopric in India. Calcutta was forthwith made a bishop's see, and Dr. Middleton was appointed the first bishop, and consecrated by the archbishop of Canterbury on the 8th of May, 1814. After receiving an address from the Society for the Promotion of Christian Knowledge, of which he was a warm supporter, requesting his aid in promoting the objects of the Society in India, and after being elected a fellow of the Royal Society, Bishop Middleton sailed on the 8th of June, and arrived in Calcutta on the 28th of November, after a voyage which he had diligently employed in increasing his qualifications for his office, especially by the study of Hebrew and Persian. As bishop of Calcutta he made every effort to promote the interests of Christianity according to the tenets of the Church of England, and to aid the cause of education. He made three visitations of his immense diocese, in two of which he directed his particular attention to the state of the Syrian Christians in the neighbourhood of Cochin, on the coast of Malabar. By his efforts the Bishop's College at Calcutta was established for the education of clergymen and missionaries for the British possessions in Asia; and he laid the first stone of its buildings on the 15th of December, 1820. He instituted a consistory court at Calcutta, and would have done the same at Madras, but for the opinion of the advocate-general at Madras that such a measure would be illegal.

Bishop Middleton died of a fever on the 8th of July, 1822, in the fifty-fourth year of his age. He was buried at Calcutta, and the greatest respect was shown to his memory both in India and at home. He was of a tall and commanding person; animated in his manner; sanguine, generous, and amiable in his disposition; and, in his religious principles, firmly attached to the Church of England. As all his papers were destroyed by a direction in his will, none of his works have appeared besides the 'Doctrine of the Greek Article,' the periodical publication mentioned above, and some sermons, charges, and tracts, which have been collected into a volume, to which a memoir of Bishop Middleton is prefixed, by H. K. Bonney, D.D., archdeacon of Bedford (Lond., 1824).

The object of Bishop Middleton's work on the Greek article is, first, to establish the rules which govern the use of the article, and then to apply these rules to the interpretation of various passages in the New Testament, many of which are of such a nature that they furnish arguments for or against the divinity of Christ, according to the different views which are taken of the force of the article. Owing to this circumstance the doctrine of the Greek article has become the subject of warm discussion among theologians; and some Unitarian divines have strongly opposed the views of Middleton. His chief rules have however been received as sound by the great majority of biblical critics. A second and improved edition of Middleton's work was edited by Professor Scholesfield in 1828, and a third edition by the Rev. Hugh James Rose, 1833. An abstract of the work is prefixed to Valpy's edition of the Greek Testament.

MIDDLEWICH. [CHESHIRE.]

MIDHEAVEN (Astronomy), a technical term for the point of the ecliptic which is on the meridian at any given moment.

MIDIANITES (מִדְיָנִים, *Madianîm*, *Μαδιανῆες*), the descendants of Midian, the son of Abraham by Keturah (*Gen.*, xxv. 2, 4), who, with the other sons of Abraham's concubines, migrated eastward from Canaan during Abraham's life (*Gen.* xxv. 6). In the time of Jacob their merchants had caravans from Gilead through Palestine to Egypt (*Gen.*, xxxvii. 28, 36). In the time of Moses we find them in Arabia Petraea, under the government of a high-priest (*Exod.*, ii. 15), and leading their flocks as far as Mount Sinai (*Exod.*, iii. 1); but they did not extend to the west of this mountain, for the Israelites did not come in contact with them in their march from Egypt, but, on the contrary, Jethro, their high-priest, came out of his country to visit Moses, when the Israelites were encamped at the foot of Sinai (*Exod.*, xviii. 1-5; *Numb.*, x. 29). They are next mentioned as living in the neighbourhood of the plains of Moab, to the east of the Dead Sea and the river Jordan.

where they suffered a defeat from the Edomites (*Gen.*, xxxvi. 35), and where they again appear as allies of the Moabites when the Israelites arrived the second time on the borders of Palestine (*Numb.*, xxii. 4). Here they corrupted the Israelites with the licentious worship of their god Baal-peor, and were punished by a dreadful massacre (*Numb.*, xxv. xxxi.; *Josh.*, xiii. 21). This calamity however fell only upon a part of the nation, for they afterwards, with the Amalekites and other eastern tribes, invaded the country of the Israelites, and destroyed the harvests, during seven successive years (*Judges*, vi. 1-3, 33). At last Gideon (*Judges*, vi. 11) defeated the Midianites and Amalekites in the plain of Jezreel, and pursued them beyond the Jordan (*Judges*, vi. 33; vii. viii.). In the time of Isaiah, the Midianites were still known as a commercial tribe (*Is.*, lx. 6), but their name afterwards merged in that of the Arabians.

The exact country of the Midianites is not determined with certainty. Some indeed suppose that those in Arabia Petræa, mentioned in *Exodus*, ii. 15, were quite a different nation from those on the east of Palestine, the former being related to the descendants of Cush (*Numb.*, xii. 1; *Hab.* iii. 7). But the more common and more probable opinion is, that the Midianites were an Arabian nomade tribe, whose possessions extended from Mount Sinai and the head of the Red Sea up towards the plains of Moab, while there may have been other bodies of them in the western part of Arabia (1 *Kings*, xi. 18). The Arabian geographers Abulfeda and Edrisi mention a town, Madian, on the eastern side of the Atlantic gulf of the Red Sea, somewhat to the north of the modern Moilah, which is probably the *Mādiana* of Ptolemy (v. 17) and the *Maḍianā* of Josephus (*Ant.*, xii. 11, 1), and of which the ruins were to be seen in the time of Eusebius and Jerome.

The Midianites were governed by their elders (*Numb.*, xxii. 4), and by chiefs or kings (*Numb.*, xxv. 15, 18; xxxi. 8; *Judges*, vii. 25; viii. 3, 5). When they invaded Palestine they were very numerous; they possessed many camels, and had acquired great wealth, probably by commerce (*Judges*, vi. 5; vii. 12; viii. 10, 24; *Is.*, lx. 6). Their religion was the worship of Baal-peor. [BAAL.]

They are twice called Ishmaelites (*Gen.*, xxxvii. 28; *Judges*, viii. 24), which is a proof of their close connection with the Arabians. (Relandi, *Palæstina*, 98; Winer's *Biblisches Realwörterbuch*.)

MIDSHIPMEN are young gentlemen ranking as the highest of the first class of petty officers on board a ship of war: their duty is to pass to the seamen the orders of the captain or other superior officer, and to superintend the performance of the duties so commanded. They are educated for their profession at the Royal Naval College, and are required to complete two years service at sea before they can be rated. Such as are appointed by the special authority of the Lords Commissioners of the Admiralty are denominated Admiralty midshipmen.

By the regulations of 1833, the whole number allowed to be entered on board a ship of war varies according to the rate of the latter; a sixth-rate ship may have eight, and a first-rate may have twenty-four midshipmen. And, on a ship being put in commission, the captain or commander may select them from the Royal Naval College, subject however to the approbation of the lords of the admiralty.

Should there be more Admiralty or College midshipmen than can be provided for, their lordships may give appointments, as extra-midshipmen, to two at most for any one ship; these must be in the places of an equal number of seamen, and they are included in the complement of midshipmen when vacancies occur.

The monthly pay of an officer of this class is 2*l.* 8*s.* for ships of all rates.

MIDSUMMER EVE. On the eve of the feast of the Nativity of St. John the Baptist, or Midsummer-day, it was long the custom to kindle fires at midnight, sometimes upon the hills, in honour of the summer solstice; a practice which Gebelin, in his '*Allegories Orientales*,' says was followed among the antient nations. In later times these were sometimes called St. John's fires; and they are still lighted in Ireland. The '*Times*' newspaper of June 29, 1833, contains an account of a riot at Cork in consequence of some soldiers refusing to subscribe money toward the fires which were to be lighted on St. John's Eve.

(Brand's *Popul. Antiq.*, 4to. ed., vol. i., p. 238; Milner's *Inquiry into certain Vulgar Opinions concerning the Catholic Inhabitants and the Antiquities of Ireland*, 8vo.,

Lond., 1808, p. 100; Vallancey, *Collect. de Rebus Hibern.*, No. I., p. 123.)

MIEL, JAN (called GIOVANNI DELLO VITE), one of the most eminent of the Flemish artists, was born in 1599. He studied under Gerard Segers, in whose school having highly distinguished himself, he went to Rome, where he especially studied and copied the works of the Caracci and Correggio. On being received into the academy of Andrea Sacchi, he gave such proofs of extraordinary genius, that Sacchi invited him to assist him in a grand design which he had already begun. But in consequence of some disgust, the cause of which does not appear, Miel abandoned the elevated subjects which had hitherto engaged his attention, declined the friendly proposal of Sacchi, and resolved to adopt the style of Bamboccio, to whom he is nowise inferior in force or brilliancy. His favourite subjects were holiday parties, carnivals, gipsies, beggars, and pastoral scenes and persons. We speak of his easel pictures, which are his finest performances; but he likewise painted historical pictures on a large scale, both in fresco and oil, which, though wanting in elevation of design and grace in the heads, are far superior to what might be expected from an artist whose subjects were in general of so much lower a class. His pictures of hunting-parties are particularly admired; the figures and animals of all kinds are designed with extraordinary spirit and truth to nature; the colouring is beautifully transparent, and the tints of his skies are extremely clear and delicate. His great merit procured him the favour of Charles Emanuel, duke of Savoy, who appointed him his principal painter, conferred on him the order of St. Mauritius, and presented him with a cross set with diamonds of great value. There are many capital pictures by this artist in the imperial gallery at Vienna; and in a grand saloon in the hunting seat at Turin there is a series of his noblest productions, representing the chase of various kinds of animals.

MIERIS, FRANCIS (called the Elder), was born at Leyden in 1635. This admirable artist was at first placed under the care of Abraham Toorne Vliet, one of the best designers in the Low Countries; and after having made considerable progress under him, he became a pupil of Gerard Douw. He soon so far surpassed all his fellow students, that Gerard Douw called him the prince of his disciples. He excelled Douw in elegance, in correctness and brilliancy of colouring, and in the art of painting silk, velvet, satin, and other rich stuffs, and was nearly equal to him in finish. His works are rarely to be seen, and more rarely to be sold, and their prices are very high. Besides portraits, he painted conversations, persons performing on musical instruments, patients attended by their physician, &c. His own price for his pictures was calculated according to the time he spent upon them, at the rate of a ducat an hour. His finest portrait is that of the wife of M. Cornelius Plants, in whose family it was carefully preserved, according to Pilkington, though very large sums had been offered for it. Some of his pictures are in the Florence Gallery. He died in 1681, aged forty-six.

MIERIS, WILLIAM (called the Younger), the son and disciple of Francis, was born at Leyden in 1662. He had made considerable progress during the life of his father; but having lost him when only nineteen years of age, he devoted himself to the study of nature. His first subjects were taken from private life, like those of his father, in which every part was copied minutely after nature. He afterwards attempted historical compositions, and his first performance of this kind was Rinaldo asleep on the lap of Armida, surrounded by the Loves and Graces, which was so highly admired, that he was prevailed upon to paint three repetitions of the same subject. He likewise painted landscapes and animals; and was so admirable a modeller in clay, that he might be ranked among the most eminent sculptors. He was inferior to his father in design, grouping, and effect; nor has he the same exquisite touch. His finishing is extremely delicate, and almost over-careful. He died in 1747, at the age of eighty-five, equally esteemed as a man and an artist. The above account is taken from Pilkington and others; but Dr. Waagen is much less favourable in his opinion: he says, 'The degeneracy of Dutch painting into mere mechanical industry, without spirit, was manifested, in all its dull sameness, in this master, most of whose works are extremely disagreeable to me.'

MIERIS, FRANCIS (called the Young Francis), was the son of William, but much inferior to him. He made

numerous copies of the works of his father and grandfather, and it is probable that such copies are put off at public sales as their performances. He is more distinguished as an historian, by his 'Historie der Nederlandsche Vorsten,' 3 vols. fol., the Hague, 1732-5; and 'Groot Charterboek der Graven van Holland, Zeeland, en Vriesland,' 4 vols., Loipzig, 1753-6. The history of his native town Leyden was left unfinished, one volume only having been published. He died in 1763, aged seventy-six.

MIGNARD, PETER (called the Roman), was born at Troyes in 1610. His name was properly More; but his father, who was of English origin, took the name of Mignard. He was at first intended for the medical profession; but as he manifested a decided talent for painting, his father placed him in the school of Jean Boucher, at Bourges, and afterwards in that of the celebrated Vouet. Having seen some capital paintings of the Italian masters, he left Vouet and went to Rome, in 1636, to study after Raphael, Michael Angelo, and A. Caracci. He spent twenty-two years at Rome, during which time he painted many historical pictures and portraits, among which those of popes Urban VIII. and Alexander VII. were the finest. In 1658 he was invited to Paris at the suggestion of Colbert, and, on his way through Italy, had the honour of painting the portraits of several of the Italian princes and their families. In France he acquired the favour of Louis XIV., who sat to him for his portrait ten times, and gave him a patent of nobility; and after the death of Le Brun, appointed him principal painter, director of the Royal collections of the Academy of Painting, and of the Gobelins manufactory. Mignard executed one of the greatest works in fresco in France, the cupola of Val de Grace. He also adorned the great hall at St. Cloud with mythological subjects, undertook several works at Versailles, and painted numerous portraits. Though Mignard was far inferior to the great models that he studied at Rome, in invention, elevation, depth of feeling, and originality, his pictures, especially his Madonnas, have much delicacy and grace; his compositions are rich; his colouring, in general, is brilliant and harmonious; and he unquestionably is in the first rank of the painters of the French school. He died in 1695, at the age of eighty-five. Nicholas Mignard, Peter's brother, two years older, was a very respectable artist: he studied two years at Rome with Peter. He died at Paris in 1668, where he was director of the Royal Academy of Painting.

MIGUEL, SAN. [MEXICAN STATES.]

MIIHEL, ST. [MEUSE.]

MILANO, THE PROVINCE OF, is bounded on the north by the province of Como, on the east by that of Bergamo (from which it is divided by the Adda), on the south by the provinces of Lodi and Pavia, and on the west by the Ticino, which separates it from the Sardinian territory. The province of Milan is entirely in the great plain of Lombardy, and is watered by the Lambro, the Olona, and other affluents of the Po. Numerous canals, some for irrigation and others for navigation, communicate with these various rivers. The soil is in most parts fertile, and the country is well cultivated, full of large villages, farm-houses, and country-houses; and the appearance of prosperity is general. The chief products are corn, rice, fruit, grass for cattle, and silk. The population of the province, exclusive of the city of Milan, in 1837, consisted of 377,324 inhabitants, and is increasing every year. The province is divided into fifteen districts: Milano, Bellate, Saronno, Barlassina, Monza, Verano, Vimercate, Gorgonzola, Gallarate, Cuggiono, Busto, Arsizio, Soma, Melzo, Melegnano. The only town, besides Milan, is Monza, ten miles north-east of Milan, with about 10,000 inhabitants, and a fine old cathedral founded by the Longobard queen Theodelinda: it contains several good paintings, and the portraits of all the sovereigns who have worn the iron crown of Lombardy, from Agilulphus, the husband of Theodelinda, to Charles V. The iron crown, so called because it contains an iron rim which is said to be made of one of the nails from the cross of Jesus Christ, is kept in the cathedral of Monza. The archives contain many valuable old documents, and some fine MSS. of the time of Pope Gregory I. Monza has also a handsome royal palace, with a vast park and gardens. The neighbourhood of Milan contains many other fine country residences belonging to the Milanese nobility and landed gentry; among others Omate, Leinato, Castellazzo, Gernietto, Villa Traversi near Desio, and Montebello. This last is memorable from having been the head-quarters of Bonaparte after the

campaign of 1797, and during the negotiations which preceded the peace of Campoformio. It was at Montebello that he decreed the destruction of the republic of Venice. The roads in the province of Milan are numerous, wide, and kept in excellent repair.

MILANO, the capital of Lombardy, and the third city of Italy, being next to Naples and Rome in population and importance, stands in the midst of a vast plain, between the rivers Olona and Lambro, with which it communicates by a canal called Naviglio Grande, which flows all round the original old town, of which it marks the boundary. This Naviglio and another canal called Naviglio di Martesana put Milan in communication with the Lago Maggiore and the Lake of Como on one side, and with the Po on the other. The suburbs, which have been gradually built outside of this boundary, and which occupy more space than the original city, are enclosed and surrounded by a line of ramparts, which is planted with trees, and serves as a promenade. This external circuit of the town is nearly ten miles. Much of the space however between the Naviglio and the ramparts is not built upon, and is occupied by gardens and fields. The population of Milan, in 1837, was 145,387. (*Bollettino Statistico*.) In 1770, when the abbé Richard wrote his tour, it did not amount to 100,000. In 1810, under Napoleon, it was 132,000. In 1816, after the change of government, it fell to 129,000, since which time it has been increasing yearly. The widest and finest streets of Milan are in the external part of the town, or suburbs: those which lead to the principal gates are called Corso, and serve as fashionable promenades. The Corso di Porta Orientale, which leads to the Bergamo road, is the most frequented. The streets of the old town are mostly narrow and irregular. The duomo, or cathedral, stands nearly in the centre of the town, and its lofty spire, which is seen from almost every part of it, serves as a directing point to strangers. This magnificent building, all of white stone, and dedicated to the Virgin Mary, was begun by Giovanni Galeazzo Visconti, duke of Milan, in March, 1386, and is not yet quite finished. The exterior, with its hundred spires and its three thousand statues of various sizes, looks like a forest of marble. The style of architecture is a kind of florid or modern Gothic; the front is of a mixed style. The interior is vast and imposing, and not loaded with ornaments. There are 520 steps to ascend, in order to reach a gallery which runs round the principal spire, from which there is a most splendid view of the whole Lombard plain, and of the chain of Alps which borders it in the form of a crescent on the north side. The churches of Milan abound with fine paintings: the famous Lord's Supper, by Leonardo da Vinci, in the refectory of the former convent of Santa Maria delle Grazie, though sadly injured, is not yet quite obliterated.

Milan is a gay, thriving, modern city: its markets are abundantly supplied with every luxury, and the citizens are generally fond of good living. Numerous coffee-houses, splendid hotels, abundance of handsome carriages, elegantly dressed pedestrians, several theatres well supplied with actors and singers,—all attest the habits of a luxurious capital. Milan has been styled 'the little Paris;' and the appellation is appropriate, for it resembles that capital rather than the other Italian cities. But Milan is also a centre of learning: it is the place of residence of several of the best Italian writers, and more books are published yearly at Milan than in all the rest of Italy. Goja, Romagnosi, and Monti made Milan their habitual residence; Manzoni, Grossi, Sacchi, and other living writers still reside in it. The fine arts are successfully cultivated at Milan, as the annual exhibition of the works of living artists proves. The engravers Longhi (lately dead), Anderloni, and others rank among the first in Italy. The museum of Brera contains several excellent paintings of the great masters; among others the Agar of Guercino, the Marriage of the Virgin by Raphael, and St. Peter and Paul by Guido. The Ambrosian library is well known for its numerous and valuable MSS., and especially for its palimpsests, derived from the monastery of Bobbio, and among which Mai discovered the treatise 'De Republica' of Cicero, fragments of several of his lost orations, the letters of Marcus Aurelius and Fronto, and other valuable remains of ancient literature. The library of Brera contains 100,000 volumes, and is open to the public. Among the private libraries, that of the marquis Trivulzio contains 30,000 printed volumes and 2000 MSS.

Milan abounds with charitable institutions. The great hospital, one of the finest and largest in the world, has been richly endowed by numerous benefactors, whose portraits are preserved within it. A singular but harmless distinction has been observed in these portraits. Those benefactors who have contributed below a certain sum are represented standing, whilst those whose donations or legacies have been more considerable are painted sitting comfortably at their ease. Four houses of refuge for poor children are supported by public contributions. Two large workhouses for the unemployed poor have been established of late years, as well as a house of correction for criminals, who are employed in useful labour, and which is said to be admirably well regulated. (*Bollettino Statistico di Milano*, January, 1833.) Milan has a savings'-bank, the deposits in which are between five and six millions of livres, or above 200,000*l.* sterling, an insurance company, a military college, a veterinary school, a conservatorio or school of music, and a school of the fine arts. For general education, there are two royal colleges or *Lycea*, three gymnasia, a clerical seminary, and three colleges or houses for female education. The elementary schools are noticed in the article *LOMBARDO-VENETIAN KINGDOM*. The Society of Arts and Sciences bestows annual prizes for inventions relating to agriculture and manufactures.

The manufactures of Milan are of some importance: they consist chiefly of silks, printed cottons, plate-glass, jewellery, artificial flowers, braid, soap, and leather.

Milan is an archbishop's see, the residence of the Austrian viceroy and of the governor-general of the Lombard provinces. It has a court of appeal, a tribunal of *prima istanza* for civil and another for criminal matters, and a commercial tribunal, called '*Tribunale mercantile e di Cambio*.'

The public gardens, the ramparts, the great parade, which occupies the site of the old citadel, and the several avenues planted with trees which lead from the gates in various directions, afford pleasant walks and rides. The climate of Milan is hot in summer, but occasionally cold and foggy in winter: it is however considered healthy.

The *Circo*, or modern amphitheatre, built in the time of the French dominion, for the exhibition of chariot and horse races, bull-fights, and other games, is of an oval form. The arena, which is about 800 feet in length, can be filled with water, and be transformed into a *naumachia* for boat-races.

The *Duomo* and *La Scala* theatre have so completely absorbed the attention of travellers, that few of them have done more than barely mention any of the other edifices, notwithstanding that Milan contains several which deserve examination on account of their architecture. Even Woods, in his '*Letters of an Architect*,' speaks only of some of the older churches, scarcely naming any one building besides, or any work of the last or present century, the theatre of *La Scala*, and the *Arco della Pace* itself, not excepted. Notwithstanding the imposing grandeur of some of the older palazzi, or private mansions, and the elegance of some of the modern ones, neither the one nor the other have been described, or rather they have scarcely been named; and yet among the former are the *Palazzo Arcivescovile*, with its façade of simple grandeur, the *Palazzo Visconti*, remarkable for the series of large busts on the pediments of the principal floor windows; the *Palazzo Annone*, by Francesco Richini, in a rather peculiar yet majestic style; the *Palazzo Marini*, now the *Palazzo di Finanza*, the work of Galeazzo Alessio, which, although impure in taste, and too much crowded, is an exceedingly rich and picturesque as well as extensive pile of building, whose principal façade exhibits three orders, a Doric, an Ionic (in pilasters), and one consisting of fluted termini, surmounted by masks or busts for their capitals. Among the more recent structures of this class is the *Palazzo Belgioioso*, by Giuseppe Piermarini (who died 1798), the architect of the *Teatro della Scala*, the *Monte* or public bank, and various other edifices; the *Villa Belgioioso*, by the architect Leopoldo Pollak (died 1800); and the *Palazzo Belloni*, the work of the celebrated Cagnola, who likewise erected the magnificent marble triumphal arch called the *Arco della Pace*. Somewhat akin to this last-mentioned structure are several of the arches or gateways forming the entrances into the city. Among these the most remarkable in point of design is the *Porta Ticinense*, or *di Marengo*, a classical propylæum of the Ionic order, presenting

a double distyle in antis, that is, one in each front, connected by lateral walls, each pierced by a single plain arch. This also was designed by Cagnola. The *Porta Nuova*, by the architect Zanoja, who died in 1817, and who is known also as a poet, is a very tasteful design, and one that shows considerable originality. The *Porta Orientale* again, with the adjoining buildings as completed a few years since by Vantini, makes a rich architectural display. Yet, with the exception of the *Duomo*, not one of these edifices, not even the gorgeously-picturesque façade of *Santa Maria presso San Celso*, the work of Galeazzo Alessio, nor the more refined elegance which stamps many of the buildings by Cagnola, Zanoja, Pollak, Gilardoni, and other modern architects, has been described by the pencil of any of our English artists, who seem to have visited Milan for no other purpose than that of delineating what is as familiar to us from prints as our own *St. Paul's*.

The *Arco della Pace* calls for more particular notice, as being one of the most splendid public embellishments of Milan, and, after the *Arc de l'Etoile* at Paris, the most important monument of the kind erected in modern times; likewise as being the principal work of its architect, the Marchese Luigi Cagnola, by whom it was commenced in 1807, and carried on until his death, August 10, 1833, after which it was continued by Carlo Londinio, and finally completed in 1837. It stands on the north-west side of the city, where it forms the entrance from the road of the *Simplon* into the spacious *Piazza d'Armi*, and is not only completely insulated, but so situated as to be seen to the utmost advantage from every point of view, particularly as regards its two principal fronts, one of which faces the noble avenue above mentioned, and the other, or that towards the city, is viewed between two elegant Doric marble buildings (serving as guard and toll houses), which are placed a little in advance of it, and are about three times the breadth of its front apart from each other. The arch, which is entirely faced with marble, and highly enriched in every part with reliefs and sculptures, besides statues both upon and in front of the attic, forms an architectural mass whose general dimensions are 72½ feet English, by 42½ in depth, and 74 in height, or including the *sestiga* and statue on its summit, the extreme height is 98 feet. Each of the principal fronts exhibits four fluted Corinthian columns, with half-columns behind them, and between them a centre arch (24 feet wide and 48 high) and a smaller one (10 feet 9 inches wide and 28 feet high) on each side of it. The entablature (the frieze of which is enriched throughout with figures of *genii* holding festoons) is not made to break over each of the columns, as in the triumphal arches of antiquity, neither is it continued unbroken throughout, as is the case in the arch in the *Green Park*, London, but it forms only a single projecting break on each side of the centre, whereby the inconvenience is avoided of such a mass of stone being suspended over the wider centre intercolumn. This disposition of the entablature has led to another novelty in the design, for instead of a statue being placed over each column, a single recumbent one, of larger dimensions than would else be suitable, is placed on these projecting entablatures. Those on the side towards the city represent the rivers *Ticino* and *Po*, on the other the *Adige* and *Tagliamento*, the two former of which were executed by Cacciatori, and the latter by Pompeo Marchesi.

There is some peculiarity in the plan of the *Arco della Pace*, there being no transverse passage through it from end to end, as in the *Arc de l'Etoile*, but merely an opening through the piers separating the larger arch from the one on each side of it, owing to which the external sides or ends of the structure have the expression of greater solidity. At each angle of the attic is a bronze equestrian statue of *Victory*, about thirteen feet high; and on the side towards the city the centre is crowned by a colossal figure of *Peace* (modelled by Sangiorgio, and cast in bronze by Luigi and Antonio Manfredini) in a car with six horses. Further than this neither description nor enumeration can be given of the various other sculptures and reliefs that so worthily adorn this magnificent work.

Milan, under the name of *Mediolanum*, was a town of the *Cisalpine Gauls*, and is mentioned by *Livy* (v. 34) and *Polybius* (b. xi.). It was taken by the consul *M. Marcellus* and *C. Cornelius Scipio*, B.C. 221. Little is said in history of Milan afterwards until the end of the third century of our era, when *Maximianus*, the colleague of *Diocletian*, fixed his residence at Milan, and surrounded it with walls,

which were two miles in circumference, and which continued to enclose the area of the town till the time of Frederic I., in the twelfth century. Valentinian II., Theodosius I., Honorius, and other emperors of the fourth and fifth centuries, resided occasionally at Milan. At the fall of the Western empire, Milan was twice devastated, once by Attila, and afterwards by the Goths under Vitiges, A.D. 539, and it did not recover from their ravages for several centuries after. The Longobard kings had their residence at Pavia, and Milan is little noticed in history during their dominion. It remained in obscurity till the latter part of the ninth century, when, under the reign of the emperor Charles the Fat, the archbishop Anspertus restored the walls built by Maximianus, and thus gave security to the inhabitants. From that time Milan recovered, and grew in population and wealth, and became gradually the principal city of Lombardy. The remainder of its history is given under LOMBARDY and LOMBARD CITIES. The present city of Milan has no claims to classical antiquity, the only solitary remains of Roman construction being sixteen handsome fluted pillars near the church of S. Lorenzo, which are supposed to have formed part of a temple dedicated to Hercules by Maximianus.

The history of Milan has been written by Corio, Ripamonti, Calco, Giulini, and lastly by Verri, who is the most critical and enlightened of the native historians, 'Storia di Milano,' with a continuation by Custodi, 4 vols. 8vo., 1825. Argelati has written the literary history of Milan, 'Bibliotheca Scriptorum Mediolanensium,' 4 vols. fol., 1745. Pirovano has published a description of Milan, 'Nuova Guida di Milano, coi suoi Stabilimenti di Scienze, di Pubblica Beneficenza ed Amministrazioni, Chiese, Palagi, Teatri,' &c., 1824. Numerous other authors have written upon particular buildings and other subjects relative to this important city. See also the *Plan of Milan*, published by the 'Society for the Diffusion of Useful Knowledge.'

MILDEW is a disease which attacks both living and dead vegetable matter, and is believed by the vulgar to be owing to fogs, dew, meteors, and noxious exhalations, but in reality is caused by the ravages of parasitical fungi. This malady is often of little importance to the subjects of its attack, as it appears towards the close of the year, when the most essential of the vital functions of plants are fulfilled, or in such a small degree as to produce no appreciable effect upon the general health of the plants infested. But it very often becomes a most serious evil, destroying the straw of corn, and so preventing the maturation of the grain, ravaging the fields of peas and beans, destroying the hopes of the gardener by seizing upon his peaches and nectarines, especially when forced, and not unfrequently extending its evil influence to the orchards and every description of kitchen-garden crop.

The species of fungi which produce these effects are always very minute, and often of microscopic smallness. Some are intestinal, attacking plants internally, and only becoming visible when they break through the surface of the plant for the purpose of shedding their spores; others are superficial, rooting and fructifying upon the outside of the epidermis. These two classes of mildew fungi require to be carefully distinguished.

Of the *intestinal* fungi the following are the more common, viz.:—

1. *Uredo foetida*, called the Pepper-brand. This plant attacks wheat, filling the young seed with its jelly-like spawn, and producing myriads of foetid deep brown spores, which end by occupying the whole interior of the ripe grain.

2. *Erineum griseum*, and other species of the same genus, which overrun the leaves of the mountain ash, the sycamore, &c., forming broad grey, orange, or brown blotches.

3. Various kinds of *Puccinia*. The mildew of wheat-straw is caused by *Puccinia graminum*, which is generated in cavities below the epidermis of the stem, and protrudes when ripe in the form of dull greyish-brown broken striæ. *Puccinia Heraclei* occasionally attacks crops of celery and endive, spreading over the field and producing the appearance of scorching.

4. *Æcidium cancellatum* occasionally does much harm to pear-trees in the orchards of Herefordshire. It appears at first like bright yellow spots upon the upper surface of the leaves; by degrees a liquid matter is exuded from them; at the same time small conical processes appear in clusters from the under side of the leaf; these processes enlarge,

P. C., No. 938.

become fibrous, open at the sides by numerous slits, and thence discharge their spores. This fungus often produces the most destructive consequences, appearing upon the leaves, stems, and fruits, and generally destroying the tree. Another species, *Æcidium laceratum*, sometimes spreads over hawthorn hedges; and the common orange-red mildew of the Berberry is *Æcidium Berberidis*.

5. *Sclerotium*, a hard kernel-like fungus, is a less common but sometimes very troublesome visitor. *S. compactum* occasionally establishes itself in the rind of fruits, rendering them uneatable; *S. Cyparissiae* and others attack the leaves of various plants, particularly of the pear-tree.

In all these cases it is usually found that the most vigorous individuals are the first affected by the mildew, especially in the case of *Uredo* and *Puccinia*; and it is probable that the spores from which these plants are propagated are drawn into the circulation from the soil, along with the fluid matter on which plants feed; that they are carried along into the stem, and begin to grow as soon as they find themselves in a suitable situation, disturbing and disorganising the tissue by the production of their spawn, and taking to themselves that nutriment which would otherwise have been applied to the general maintenance of the plant attacked. Mr. Bauer found that he could always cause wheat to produce the *Uredo foetida* by rubbing its grains with the spores of that fungus previous to their being sown; and Mr. Knight ascertained that by sowing pear-seeds in soil infested with the *Æcidium*, the very youngest leaves of the seedling plants were attacked.

Of *superficial* fungi the following are the most remarkable:—

1. *Cylindrosporium concentricum*, a pulverulent species, which appears in dots arranged in a circular manner upon the leaves of the cabbage.

2. *Acrosporium monilioides*.—A frequent cause of the whiteness of leaves and stems in roses, &c. It consists of vast multitudes of filaments jointed like a necklace.

3. *Botrytis diffusa* and species of the genus *Aspergillus*, whose filaments bear tufts or branches, covered with spores. These form the white mealy appearance of the leaves of onions and similar soft-leaved plants.

4. *Erysiphe communis*, which forms the mildew of peas. It consists of white cobweb-like spawn, radiating from a solid grey spherical centre, filled with the spores of the species. Peach mildew is often caused by another of this genus, the *E. pannosa*.

The attacks of superficial fungi are generally brought on by the debility of the species attacked; and it is probable that unhealthy individuals only are suited to the growth of these parasites. This is like what occurs among animals, which, when healthy, are scarcely attacked by parasitical vermin, but as soon as they become sickly are overrun by them. Heavy rains occurring suddenly after long drought are mentioned as a cause of this kind of mildew; and it may be supposed that the plants are debilitated by the dry weather, at which time the fungi seize upon them, and that as soon as rain falls they grow with rapidity and quickly overrun the plants. It is said that deep-coloured roses and peaches are more liable to mildew than others; this may be referred to constitutional debility, for their colour is connected with a want of power to decompose carbonic acid, which is one of the most indispensable of vital functions in the vegetable kingdom. Transplanted onions, which are less vigorous than untransplanted ones, are the most subject to mildew.

These causes of mildew being rightly understood, the methods of preventing the evil are sufficiently obvious. To cure intestinal mildew the soil should be neither too rich nor too freely watered, and every precaution should be taken to prevent the spores of the mildew-plants from being communicated to the soil. Mr. Knight stopped the attacks of *Æcidium cancellatum* by taking up his mildewed pear-trees, washing their roots clean, pruning them closely, and removing them to a new situation; those removed became healthy, those left in the soil eventually perished. It would also appear that in some cases plants may be rendered incapable of taking the mildew. Mr. Bauer says that if corn attacked by pepper-brand is soaked in lime-water for at least 12 hours and then well dried in the air, before sowing, not only are all the fungi adhering to it destroyed, but the plants themselves are incapable of nourishing the fungus; at least he found that prepared grains could not be inoculated, although unprepared grains could be. With

VOL. XV.—2 E

regard to destroying superficial mildew, a restoration of vigour or its preservation seems to offer the best chances of success. Mr. Knight prevented his peas from mildewing by watering them abundantly and constantly; in Scotland, where the climate is more equable than in England, and the night dews more abundant, pea mildew is unknown; the writer of this has seen a crop of onions, perishing under the attacks of *Botrytis diffusa*, gradually restored to health by a constant supply of water. As to the schemes of stopping superficial mildew by the application of sulphur, quick-lime, fresh wood-ashes, and similar substances, all of which have been recommended, it does not appear that any advantage follows their employment. When trees are attacked by superficial parasites, the best plan of removing the evil is by cutting off all the mildewed branches and destroying them, together with shreds, nails, or whatever else may have been made use of in training the plants. Mr. Hayward recommends in addition that peach-trees, which are very liable to mildew, should be subsequently washed with a fluid consisting of 4 gallons of rain-water, 2 lbs. of soft soap, 1 lb. of flower of sulphur, 1 lb. roll tobacco, 1 quart of fresh-slaked lime, and 1 pint of spirits of turpentine, the whole boiled together for half an hour.

MILE. This word is derived from *miliare*, the *mille passus*, or thousand paces, of the Romans. Each pace was five feet, and each foot certainly contained between 11·60 and 11·64 modern English inches. [STANDARDS OF LENGTH.] Taking the Roman foot at 11·62 English inches, the original Roman mile was therefore 1614 yards, or nine-tenths and one-sixtieth of an English statute mile, very nearly; while the English mile is a Roman mile and nine hundredths of a Roman mile.

The English statute mile is 8 furlongs, each of 220 yards, or 40 poles of 5½ yards or 16½ feet each. It is also 80 surveying chains of 22 yards each. It is therefore 1760 yards, or 5280 feet. The square mile is 6400 square chains, or 640 acres.

The remains of the Roman mile and the Gallic or Celtic league [LEAGUE] are found in the itinerary measures of most European countries. The following list (taken from Kelly's 'Cambist,' except the statement of the Roman mile) will show the itinerary measures of various countries, as they are usually reputed in English yards and statute miles. We have placed them in order of magnitude. The last column shows in round numbers how many of each make 1000 statute miles:—

Yards.		Stat. miles.	No. in 1000 St. miles.
1614	Antient Roman mile	·917	1091
1628	Modern Roman mile	·925	1081

The metrical mile of 1000 French metres, or one kilometre, or 1093 English yards, is put down among the measures of France, Italy, and the Netherlands; the geographical mile, or the sixtieth of a degree of latitude, or about 2025 yards, is used in England and Italy; the geographical league of three such miles, or 6075 yards, is used in England and France; the German geographical mile is four English geographical miles, or 8100 yards; the short mile used in Poland (which is also the league of Brabant) is the geographical league (6076 yds.), and the long mile of the same country is the German geographical mile (8101 yds.), which is also the length of the mile in Holland. The Arabian mile is 2148 yards; the Chinese li 632 yards; the

Persian parasang 6086 yards; the Russian verst 1167 yards; and the Turkish berri 1826 yards. All the preceding statements relative to modern measures rest on the authority of the work cited.

This diversity of itinerary measures, particularly as observable in countries which were formerly under Roman sway, can only be conjecturally explained; partly by supposing that the mile (Roman) and the league (Celtic) were in process of time confounded with each other (as Ingulphus asserts to have been the case in England), partly by recurring to the well-known tendency to give the same name to measures which were multiples one of the other. [LEAGUE.] It would be much beyond us to attempt any derivation of the preceding anomalous measures, either from the mile or the league, and we shall in the present article confine ourselves to the history of the English mile.

It will be necessary to treat this subject at some length, on account of the manner in which our metrologists and antiquaries have passed it over. The legal history is simply this; that previously to the reign of Elizabeth the statutes on weights and measures confined themselves entirely to the regulation of the smaller standards; while in the 35th year of that queen an act was passed which (perhaps undesignedly on the part of its framers) has fixed the mile at its present length. This statute, though it is always appealed to as if made for the purpose of settling the question, yet in fact does nothing more than incidentally define a mile for a particular purpose. Persons are forbidden to build within three miles of London, and the mile is to be 4 furlongs of 40 perches of 16½ feet each. But whether this mile had become common, and only wanted the sanction of law, whether it was a new measure intended to be generally enforced, or whether it was meant as the measure for the particular purpose indicated, and for that purpose only, cannot be gathered, at least from the recital in the Statutes at large. It will however subsequently appear that we are not without something like a probable account of the derivation of the measure; and whatever doubt may rest upon the meaning of the statute, it was considered by an authority of the reign of James I. (Cowell) as a general declaration of the length of the mile. Previously however to the act of Elizabeth it may be doubted whether any uniform mile was in existence. Most unquestionably many, perhaps most, writers made use of a mile of 5000 feet, probably not being aware of the English foot having become longer than the Roman, and intending to use the Roman mile. (See the citations in LEAGUE.) Thus Roger Bacon, in his general description of the earth, follows (except as hereinafter mentioned) the Latin writers, and uses their mile as a matter of course, without the least warning of his being aware that he was using a measure different from the popular one of his time. In a writer then on any mathematical or cosmographical topic the mile may be presumed to have 5000 feet. If however the subject had any connection with astronomy, and if Arabian writers were referred to, it was not unusual to use the Arabian mile of 2000 yards (according to Roger Bacon's estimation, Jebb, p. 141).

If, as we believe we shall presently show, a longer mile was in popular use, it may be doubted whether the authors above alluded to were aware of the difference. They certainly did not perpetuate such knowledge; for Dr. Bernard, the most profound of English metrologists, found the mile of 5000 feet sufficiently common in old writings to induce him to give it a name, and call it the English *geometrical* mile, meaning, we suppose, that principally used in mathematical writings; but he does not give the least hint that any other mile, except this geometrical mile and the statute mile, was ever in existence. Nor does his predecessor Greaves, when he remarks that great differences have been observed between measured and statute miles, hint at such discordances being derived from the remains of an old and different measure, or at any acknowledged measure different from the statute mile. This mile of 5000 feet continued in use among seamen, whose measures depend more upon writers on navigation than on acts of parliament, until the earth's dimensions became better known. A very old notion as to the earth's magnitude gave 60, or at most 62½, Roman miles to the degree. The sea mile tallied with that of writers on shore, until the measures of Picard, &c. became well known; but the sixtieth part of a degree of latitude is so convenient a standard measure for the sailor, that under the name of a nautical or geographical mile it

has lengthened with the common estimation of the degree of latitude. Thus in the time of Gunter we find the degree described as 60 miles of 5000 feet each; though he certainly says (*On the Cross-Staffe*, b. xi., cap. 6), that by comparison of observations,* he thinks 352,000 feet nearer the truth. Even almost as late as the Revolution common works written for landmen describe the sea league as three Italian miles, which answers nearly to 15,000 feet. By the time of Dr. Bernard however we find the sea mile described as coinciding with the statute mile (*De Mens. et Pond.*, p. 202); but this is in a work of science and authority: and Oughtred (before the date of Bernard's book) says that it is 'taken' (or rather mistaken) that 60 statute miles make a degree. It is most likely that the sea league would in the first instance be taken from the common league; and certainly 15,000 feet, or 2·84 statute miles, is almost the same as the length which different deductions will give for the old land league.

We now proceed to the main question, the length of the old English mile: premising that the utmost we can attempt is a clear proof that the old popular mile differed considerably from the modern mile. The gradual changes of this old mile (which the general history of itinerary measures may lead us to suspect) must be traced out by closer investigation of antiquarian authorities than mathematicians have been wont to make, and better estimation of their relative values in a mathematical point of view than antiquaries have hitherto been capable of making.

There is a *tradition* among antiquaries (Sir H. Ellis, *Preface to Domesday*) that this old mile was somewhere about a statute mile and a half. This tradition is not to be relied on; for though in all probability it agrees with the truth, yet it may have arisen from another circumstance. We have more than once heard it proved by the assertion that, even within the memory of man, distances were measured in the remote parts of the country by a longer than the statute mile; for instance, that York was said to be 150 miles from London, while it is really more than 199 statute miles. This is perfectly true; but the reason is perhaps different from that given, as the following account will show:—

The first actual measurement of the roads in England, in statute miles, was made by John Ogilby, cosmographer to Charles II., and was published by him in 1675, under the title of '*Britannia*,' with copious descriptions, and 100 copper-plates of the roads, in a large folio volume: the instrument used was called by him a *wheel-dimensurator*, and answers entirely to the perambulator now in use. Various editions of this work were published, of which we have seen three, and D'Anville mentions a fourth. It is worth noting that this measurement, as compared with older ones, soon came into general use: thus in a little work for men of business, called '*The Complete Tradesman, or Exact Dealer's Daily Companion*,' London, 1684, we find a list of Ogilby's distances from town to town, compared with those formerly adopted. The latter were called by Ogilby *computed* miles, and the meaning of this word might be doubted, but it is proved to mean miles in common use by previous publications. Thus in Samuel Morland's '*Description and Use of Two Arithmetic Instruments*,' &c., 1673 (or two years before Ogilby's publication), we find the distances called '*computed*' by Ogilby set down as the (supposed) real distances. D'Anville appears to have seen an edition of Ogilby (of which there is one at least) in which the word *computed* is always contracted into *com.* This he supposed to mean *common*, and the whole of his chapter on English itinerary measures (*Mesures Itinéraires*, cap. x.) must in consequence be read cautiously, as he assumes it to be indisputable that there was a common mile in use at the Revolution, which was about a quarter longer than the statute mile. But on the authority of the silence of Bernard and Greaves, above referred to, we must remain of a different opinion, and must suppose that the computed miles preserved by Ogilby had been intended to represent the number of statute miles, but erroneously given.

What then may these computed miles mean, which had served the common purpose in the estimation of distances? The word *computed* never meant *reputed*, but was always applied to a result of reckoning of some kind or other. Ogilby says, 'Whence these computations arose is altogether uncertain; the nearest conjecture is, that they seem to ex-

clude the whole length of the towns, and to be the distance from the end of one town to the beginning of the next, not regarding the fractional parts of a mile, but taking the lesser integer.' The computed miles always give a smaller figure than the measured ones, or the same, never a greater; and a little examination will render it difficult to suppose that the preceding explanation can be the true one. For independently of its having been the known practice to measure the roads from a conspicuous part of every town, the preceding will not explain differences of four, five, and even seven miles in a stage of less than thirty; neither will it explain long stages being often of the same number of computed as of measured miles. Our own conviction is that the computed miles are nothing more than distances measured on a map in a straight line from town to town, which differ from those measured on the roads more or less, according to the deviations and curvatures of the roads. Should this opinion be correct, we might expect beforehand, first, that the roads in the neighbourhood of the metropolis would appear more direct than the general average; secondly, that the principal roads would show indications of being more straight than the average deduced from all classes, and from cross as well as direct roads. Both these things appear in the general results, and we can clear ourselves of the suspicion of bias in our selection of instances by throwing that task on others. In the first place the roads near London agree so much better in the computation, so called, and the measurement, that both Ogilby and D'Anville notice the circumstance, and conclude that a shorter mile was in use in the neighbourhood of the great city. We find on examination that such is the case with most of the twenty-mile distances about London, which yield about 120 measured miles for 100 computed miles; and this happens particularly with those routes which come earliest in Ogilby's work; but 120 would have been increased almost up to the general average by taking twenty miles on every road out of London.

Secondly, in the '*Exact Dealer's Daily Companion*,' already quoted, there is a selection of the roads to which most importance was attached, upon the whole of which 3953 computed miles answer to 5020 measured miles, or 100 computed miles give 127 measured miles. According to D'Anville, Ogilby's whole work gives 7679½ measured miles of road, and 5765 computed, so that 100 computed miles make 133 measured miles. Hence the remaining 2679 measured miles give 1812 computed miles; or, off the principal roads, 100 computed miles give 147 measured miles. These results place, in such large numbers of miles, insuperable difficulties in the way of any explanation which should equally apply to the greater and lesser roads; and it seems to us that there remains only the hypothesis that the computed miles were map-measured* distances, and that the larger and more important roads were straighter than the rest.

It is believed that, since the time of Ogilby, the roads have been much shortened by the various acts of parliament. *Have the milestones been altered accordingly?* or has the increased speed of stage-coaches been in part the result of calling a shorter line of road by the same number of miles? To try this question, we shall compare a few distances from place to place, as given in Ogilby's '*Britannia*,' with those in Mogg's edition of Paterson's '*Roads*' (1824), altered so as to start from the same point, namely, the old standard in Cornhill:—

	Ogilby.	Mogg.
London to Worcester	112	114
„ Berwick	339	337
„ Bristol	115	117
„ Bridgnorth	142	142

The measures in Ogilby may of course be erroneous; but as they were certainly made with a sufficient instrument, and exhibit every appearance of care, and as in our country it is nobody's business to see that all succeeding milestones are altered when a mile of road is saved in the middle of a line, we suspect strongly that a remeasurement would show our present distances to be too long.

The credit of the antiquaries' tradition, which would otherwise be considerable, is destroyed by its probable origin, as above stated. We now come to another species

* This of course refers to the measure of Suell, which gave 353,235 feet (A.D. 1616).

* If our hypothesis be correct, these computed miles should represent distances on an incorrect map, which in fact they do. We found them agree somewhat better with the county maps in old editions of Camden's '*Britannia*' than with our modern maps.

of evidence, the testimony of foreign writers. The new measures of any country found their way abroad but slowly at the beginning of the seventeenth century, and we shall not therefore be surprised to find foreign writers of the middle and end of that century varying from then existing measures in their statements. We shall first take the geography of Varenus, first published in 1650, and edited in 1672 by no less a person than Newton, then Lucasian professor. The following sentence was allowed by the editor to pass without comment:—‘Triplicia habent Angli miliaria: majora, quorum 27½ æquant gradum sive 19 Hollandica; medioeria quorum 50; minima quorum 60 vel 55.’ Now the mile of Varenus is described by himself as containing 18,000 Rhineland feet, each of which, according to Dr. Bernard, is 1·033 English feet. Whence it may be deduced that the three miles described as English by Varenus severally contain 2·43, 1·33, and 1·11 statute miles (taking ‘60 vel 55’ to be 60). We have no doubt that Varenus has here got hold of the leuca, the old mile or half the leuca, and the modern statute mile, which, being not sixty years old when he wrote, was not, though the contemporary legal measure, more accurately known than the others. Again, Ozanam, in his ‘Mathematical Dictionary,’ A.D. 1691, makes the English mile a quarter longer than the Italian mile, that is, considerably above the statute mile; but his accounts of itinerary measures are so evidently theorised into round hundreds and thousands of geometrical paces, that no dependence can be placed on any specific results drawn from them. If his geometrical pace be five French feet (Paueton, p. 179), this English mile (which he states at 1250 paces) is 6250 French feet, or 2219 English yards, that is, 1·26 statute miles. But this is hardly worth notice, for no value of the geometrical pace can be taken which will make Ozanam’s account of measures consistent with itself. We shall take one more conjectural determination of the mile, derived from the sea league of the seventeenth century. Gunter states this at three miles of 5000 feet in a mile, the league being the twentieth of a reputed degree. The author of the ‘Exact Dealer’s Daily Companion,’ above cited, calls it three Italian miles, or 4904 yards. Now if the original league were the land measure, then the mile (or half of the leuca) would have been 2452 yards, or 1·4 statute mile.

D’Anville endeavours to make the old mile the same thing as the original French league, or the Roman mile and a half [LEAGUE], taking the *computed mile*, already discussed, as the old measure. But independently of the mile thus considered not being long enough (and we have no instance of an itinerary measure shortening by time), the distinction between the mile and the league seems to have been one of the most common notoriety from the time of the earliest manuscripts; and previous to this time the confusion which might have made D’Anville’s supposition true had already lengthened the league by 500 paces.

The only way of detecting the length of any measure, a copy of which is not absolutely preserved, is by the knowledge of some quantity, which having been handed down in terms of the old measure, and being still in existence, can be re-estimated in terms of the new measures. Unfortunately we have no very exact measurements of well-known lengths; nevertheless by using such as we have, and taking the mean of a considerable number, the odds are much against any very serious error remaining in the result.

About 1478 William Botoner, commonly called William Wirecestre, or William of Worcester, made a tour in various parts of England, and wrote, apparently for his own use, a large number of memoranda, which remained in the library of Corpus Christi College, Cambridge, and were published in 1778, by Dr. Nasmyth, with the title, * ‘Itinerarium Wilhelmi de Worcestre.’ The date of the writer is well settled, for he asserts that in the year 1473 he presented to the bishop of Winchester his own translation *into English* of Cicero de Senectute. This William of Worcester was given to measurement: he records the dimensions of the churches which he visited, and the number of miles between the several towns. From the latter enumerations we have collected the most definite instances, which we have compared with our latest road books, as follows (W is the number of miles in W. of W.’s account; R in the road-books):—

	W.	R.
From Oxford to Farringdon . . .	12	17½
„ Farringdon to Wooton Bassett . . .	15	9
„ Gloucester to Tewkesbury . . .	7	11
„ Shepton Mallet to Glastonbury . . .	5	8½
„ Glastonbury to Bridgewater . . .	9	15½
„ Bridgewater to Taunton . . .	7	11½
„ Taunton to Wellington . . .	5	7
„ Wellington to Collumpton . . .	10	12½
„ Collumpton to Exeter . . .	10	11½
„ Ottery St. Mary to Exeter . . .	10	13
„ Plymouth to Saltash . . .	3	4½
Totals	93	131½

To give the best chance of a correct result which our present means afford, we must increase this 131½ modern road miles in such proportion as will make them correctly represent the same roads at the time when William of Worcester travelled. This we have no data for doing, and any supposition we may make must rest on its own intrinsic probability. To neglect this correction altogether would make the preceding give 100 old miles equal to 141 statute miles, and this is the lowest conclusion which can be formed. But if five per cent. of deviation has been corrected since the old account, that is, if what is now 100 miles would have been 105, then 100 old miles may be stated at 148 statute miles. This conclusion, and even a stronger one, may be reinforced from a totally distinct quarter. But first let it be observed, that since roads have no tendency to lengthen, but the contrary, it may be inferred that such of the preceding instances as make the old mile least are most probably those in which the distances have been shortened; and instead of being the cases of most weight, are precisely the reverse.

Though the preceding instances are quite sufficient, yet it may be satisfactory to name one or two short distances in which a very large mistake is impossible. The following, were they the only ones, would lead us to suspect that the old mile was even longer than a mile and a half statute. William of Worcester says that Wokey Hole is about half a mile from Wells, whereas, by the Ordnance Map, it is a mile and six-tenths in a straight line from the centre of the town. Again, Merkysberry (now Masberry) Castle is placed by him at two miles from Wells on the opposite side: it is now three miles and three-quarters in a straight line from the centre of the town. Lastly, Fenny Castle is said to be a mile and a half westward towards the marsh, whereas what is now called Castle Hill is two miles and three-quarters westward. These instances are more convincing than the preceding as to the mere use of a longer mile, though not so well adapted for its determination.

We must now remove the question to Palestine. In the description of the earth given by Roger Bacon (Jebb, pp. 180-236) he generally follows Pliny, and gives distances in Roman miles, except only when treating of those parts which the Crusaders visited, and other Eastern countries. In this part of his account Bacon relies much on the conversation and writings of a certain Willielmus, who went on a mission from the king of France to the Tartars in 1253, and on the oral accounts of other travellers. But the country on the distances of whose towns he is most precise in his information is Palestine itself. By taking fifteen well defined instances, and measuring the corresponding distances on Major Rennell’s map in parts of inches, we have the following, the first column being the number of leucæ in Bacon, the second the number of inches in Rennell. (We omit sea-distances, as likely to err considerably.)

	B.	R.
From Gaza to Ascalon . . .	9	·65
„ Ascalon to Joppa . . .	12	1·12
„ Joppa to Aco . . .	24	2·48
„ Aco to Cæsarea . . .	12	1·10
„ Aco to Tyre . . .	9	1·18
„ Tyre to Sarepta . . .	4½	·49
„ Sarepta to Sidon . . .	3½	·34
„ Sidon to Baruth . . .	8½	1·10
„ Baruth to Gibelet . . .	9	·87
„ Gibelet to Tripolis . . .	9	1·21
„ Jerusalem to Joppa . . .	12	1·50
„ Jerusalem to Jericho . . .	9	·67

„ Samaria to Cæsarea . . .	12	1·03
„ Aco to Nazareth . . .	7	·72
Totals	152½	16·03

* With it was published the ‘Itinerary of the Holy Land,’ by Simon Simeon, and whoever would consult the book at the Museum must look under the latter name in the Catalogue. With it was also published the tract on Leonine Verses referred to in the article on that subject.

The scale of Rennell's map is three inches to a degree of latitude; and the only remaining question is, how much must this 16·03 inches, which is a total of distances measured in the shortest lines from place to place, be increased to allow for the deviations of the roads? If we assume that the deviation was equal to that in England at the Revolution, we must* increase 16·03 in the proportion of 100 to 127, which gives 20·3581. It must be remembered that the more allowance is made for deviation, the longer is the leuca; and we think it is the least supposition which can be made, to suppose the deviation on routes in Palestine no greater than in England. Dr. Bernard states that it was the practice of the Oriental geographer Abu Rihan (Al Biruni or Birunius) to deduct one-fifth from distances measured on the roads, to obtain the true distances in a straight line. This amounts to increasing the number of miles measured on the map in the proportion of 100 to 125, and is practically accordant with the preceding rule in a question of which the data are as rough as in the present one. The testimony is valuable as referring to roads in the East, and at the period to which Bacon's account refers. The leuca is then, on these suppositions, ·1335 of an inch on Rennell's map, or ·0445 of a degree. The length of the degree in these latitudes being assumed at 363,500 feet, we deduce 3·064 statute miles as the length of a leuca, or 1·532 statute miles as the length of the old mile. If we were to reject the correction for deviation, the result would be 1·206 statute miles, which is unquestionably too small.

In 1422 Sir Gilbert de Lannoy was sent by Henry V. of England on a tour of military observation in Egypt and Syria. His account is published (from a manuscript in the Bodleian) in the 21st volume of the 'Archæologia.' He never mentions the league more than once or twice, and gives all his distances in miles. From his account of Egypt we soon found that no hypothesis would make his distances agree with modern travellers. He places the city of Cairo, for instance, three miles from its port Boolak, which distance is now called only *one* mile. [KAHRA.] But on examining his distances in Palestine there appears almost a certainty that he used a smaller mile, of which two and a half (and not two) make the league of Roger Bacon. The following are all the comparisons which his work affords us the means of making:—

	Bacon. Leagues.	Lannoy. Miles.	League in Miles.
From Joppa to Aco	24	60	2·5
„ Aco to Tyre	9	25	2·78
„ Tyre to Sidon	8	20	2·5
„ Sidon to Baruth	8½	25	2·94
„ Jerusalem to Joppa	12	30	2·5

But even Lannoy's mile must be longer than our statute mile; and it is difficult to explain the difference. One thing is certain, that Lannoy's mile in 1422 cannot be the same thing with that of William of Worcester in 1473, or that of Bacon in 1250, being shorter than either.

So far our conclusions proceed upon assumptions of the highest probability; and the result is, that from the English measurements we may infer that 100 antient miles certainly exceed 141 statute miles, while from those in Palestine they are most likely not much less than 153 such miles. It is highly probable that the result is nearer to 153 than to 141. If we were to take a mean of both results, giving them equal weights, the mile thus obtained would be probably too small, and this result is 1·47; so that (as mentioned in LEAGUE) the ratio of 145 to 100 (misprinted 45 to 100) is the very least which is admissible, and perhaps too small even for a minimum. It seems to us that a more probable result would be obtained by taking 153 as a result of the measure in Palestine (for it is hard to believe that the correction for deviation could have been too much), and giving this number twice as much weight as 141 in forming a mean of the two. This gives 149 in place of 147; or, roughly speaking, we think it by no means improbable that 100 antient miles are as much as 150 statute miles, and tolerably certain that they exceeded 145 such miles. At the same time there is evidence enough that very different miles were in use among writers, and also that the most ignorant confusion between antient and modern measures frequently existed. Sir John Maundevile, for instance, says, 'Aftre the auctoures of astronomye, 700 furlonges of erthe answeren to a degree of the firmament: and the

ben 87 miles and 4 furlonges. Now be that here multiplied by 360 sithes; and than thei ben 31,500 myles, every of 8 furlonges, aftr myles of oure contree.' The old astronomical authors use the stadium, which is here made to be the English furlong, a measure with which it had no connection.

There is certainly this difficulty in the way, that [LEAGUE] the antient minimum distance between two market-towns must have been 19 modern statute miles, which seems a great distance. But it must be remembered that this appearance is a consequence of the notions derived from the modern interpretations of the courts, which make the leuca to be a statute mile; so that seven miles has long been the legal distance. This interpretation is so preposterous that it must be thrown aside; for even if the mile of Bracton and Fleta were the mile of the *books*, and not the mile of the *people*, the leuca would be 10,000 feet, or two statute miles all but the tenth of a mile. And the reason given by Bracton certainly requires some greater distance than seven miles. For he implies [LEAGUE, vol. xiii, p. 376] that the third of a day's work should be half the distance of two markets; and gives a time for buying and selling not longer in duration than that allowed for going to the market. Reading this paragraph by the modern interpretation of the courts, the time of business would be that in which a laden horse or market-cart would go three miles and a half; and if, taking into account the badness of roads in the fifteenth century, we allow even as much as two hours for this, then the day's work would be only six hours. According to our reading the time of going nine miles and a half would be the time of business; or allowing three miles an hour, the day's work would be something more than nine hours. It may however be possible, and not improbable, that the mile of 5000 feet, or that of the books, was that of the courts of judicature, which would give about 12½ statute miles as the distance in question.

We conjecture that the length of the antient mile arose from that confusion between the mile and the leuca which is referred to by Ingulphus. [LEAGUE.] The leuca of fifteen hundred paces would, when the foot attained its permanent length, be 1·42 modern statute miles, to which the term mile being applied, we have the probable beginning of the old mile, that is, we adopt D'Anville's conclusion on different grounds. If in the meanwhile the leuca of 2000 paces came into use (as, according to Ingulphus, it did), which would be called in the books two miles (as in fact it was two miles of the *writers*), it is by no means surprising that a new leuca of two long miles should be formed from the mile of the people. This would be but a poor conjecture for the establishment of a measure; but it has great force in reference to a mile, the existence of which is separately proved. And though Ingulphus states that the word leuca was introduced as meaning a mile, yet it is more likely that the new measure should have been introduced under the old name, than the new name for the old measure: it is moreover tolerably certain that the conquerors would attempt to introduce both their measure and its name, while the people would be able to resist the latter, but not the former.

The origin of the statute mile may perhaps be explained as follows:—The furlong, or quarantena, was not a part of the Roman itinerary system of measures. It grew out of the perch, or perticata, a measure originally of small lengths, as in buying or selling of land, 40 of which were made into one by the simple name of forty-long, or furlong. The great variations of the perch, in different parts of the country, induced the legislature, at a very early period, to fix it at five yards and a half. It did not harmonise with the book-system of measures, and we see [LEAGUE] that when it was introduced there, the mile was awkwardly described as seven furlongs and a half, three perches, and two palms. The legislators of Elizabeth, who were well acquainted with the stadium, seeing the mile of the books (and perhaps of the courts) making upwards of seven furlongs and a half, might very naturally restore the nominal accordance of the old and modern systems, and at the same time avoid fractional quantities, by lengthening the mile into eight furlongs.

MILFORD HAVEN. [PEMBROKESHIRE.]

MILHAU, a town in France, in the department of Aveyron; in 44° 5' N. lat. and 3° 5' E. long.; on the road from Paris to Narbonne, through Moulins, Clermont, and St. Flour: the distance is not given in the road-books.

Milhau is said to have been known to the Romans by the

* We take this from some rough trials, out of Ogilby's book, but we rely more on the eastern geographer presently mentioned.

name of *Æmilianum*, a name which indicates a Roman origin. It is not however noticed by D'Anville. In the religious wars of the sixteenth and seventeenth centuries, it was one of the strongholds of the Calvinists. Louis XIII. possessed himself of it in A.D. 1629, and ordered the fortifications to be destroyed. The town is situated on the right bank of the Tarn, in a pleasant valley surrounded by hills covered with peach and almond trees. It is well laid out, but the streets are narrow. Many of the houses and the public fountains are handsome: there is a good 'place' or square and some agreeable promenades. There is a bridge over the Tarn, supposed to be of Roman erection.

The population, in 1831, was 8847 for the town, or 9806 for the whole commune; in 1836 it was 10,450 for the commune. The inhabitants manufacture a considerable quantity of woollen cloth, serge, chamois and other leather, and gloves. Cheese, which resembles the 'Roquefort cheese,' and is sold under that name, is made in the neighbourhood in cellars hollowed out of the rock. Considerable trade in raw and spun wool, leather, timber for various uses, wine, and sweet and bitter almonds, is carried on. There are a subordinate court of justice, a commercial court, a board of trade, and some fiscal government offices; an agricultural society, a high school, a drawing-school, and an hospital. There is a Protestant church, under the direction of the consistory of St. Afrique.

The arrondissement of Millau has an area of 772 square miles, and comprehends 39 communes: it is divided into 9 cantons or districts, each under a justice of the peace. The population, in 1831, was 63,603; in 1836, it was 65,800.

MILIOIA, a family of FORAMINIFERA, vol. x., p. 348.

MILITARY FRONTIER (Hungary). This is the name given to a tract of country which extends from the Adriatic Sea to the Bukowina, between the frontiers of Illyria, Croatia, Slavonia, Hungary, Transylvania, and those of Turkey. Its length is about 1000 miles, from Povele, on the Adriatic, in 16° 48' E. long., to the defile of Ostocz, in 26° 25' E. long., and it lies between 44° 7' and 47° 36' N. lat.; its breadth varies in different parts: the area is about 18,000 square miles. The whole of this tract is divided into—1, the Western or *Croatian Military Frontier*; 2, the *Slavonian Military Frontier*; 3, the *Hungarian or Banat Military Frontier*; 4, the *Transylvanian Military Frontier*.

This tract is distinguished from the rest of the Austrian monarchy by having its own purely military government. All the peasants are soldiers, of whom, in time of peace, 45,000 men are always under arms; but in 1815, before the peace, there were 62,000. This force was originally intended as a barrier against the inroads of the Turks. By this tenure the peasants hold from the state the hereditary usufruct of their lands. This singular institution secures to the state the services of a great military force (there being above 100,000 men capable of bearing arms), which in time of peace costs the state nothing. These well-trained and disciplined soldiers defend their own frontier both against hostile attacks and the plague without pay, and in time of war serve the state in the same manner as the rest of the army, and receive the usual pay. They are divided into seventeen regiments of infantry, one of hussars, and one battalion of sailors. Each regiment consists (in time of peace) of two battalions, or twelve companies, which serve in turn, has its own staff, and is commanded by a colonel, who exercises both the civil and military authority. Two regiments make a brigade. The military authority is divided among what are called four general commands, the seats of which are, at Agram for the Croatian frontier; at Peterwardein for the Slavonian; at Temesvar for the Hungarian; and at Hermann for the Transylvanian: the whole is under the supreme direction of the Aulic Council of War at Vienna. According to the military constitution, the generals superintend the civil affairs and the administration of justice. Under the general are the regimental commanders, who are in the place of district authorities; in short, all civil officers hold military rank.

Face of the Country; Soil; and Climate.—A great part of the country is mountainous, the western part being traversed by the Julian Alps, and the eastern by branches of the Carpathians. Many fine valleys, some of them rich in picturesque beauty, lie between the branches of the mountains: the remainder of the country is pretty flat. The western part of the Banat is a sandy plain covered with sandhills from 60 to 180 feet high. On the banks of the Danube, the Theiss, and the Temes, there are extensive marshes. In the mountainous parts the temperature is

that of more northern countries; whereas the lower central parts enjoy a climate resembling that of Italy. The soil is on the whole very fruitful, especially in the plains, and in several valleys of the Banat. For the natural productions, see HUNGARY.

Manufactures.—There are no manufactures of any importance. The women, as well as the men, show great skill and ingenuity in manufacturing almost every article for their own consumption. There is a very great export trade in the productions of the country. The extensive forests supply great quantities of excellent timber. That of Jablanacz is much esteemed in England for ship-building.

Variety of Nations; Languages; Religion; and Education.—The population is at present (1839) at least 1,200,000, and is of many different races, two-thirds however being of Slavonian origin, namely, Croats, in the Croatian Military Frontier, and the Slavonians and Servians (Illyrians or Russians), in Slavonia and the Banat. The three other principal nations are less numerous, namely, the Wallachians (perhaps above 150,000), in the Transylvanian and Banat Military Frontier, and the Hungarians and Szekler in Transylvania. Besides these there are Magyars, Germans, Greeks, Jews, and Gipsies. The Clementines are of Albanian origin, so called from their leader Clement. They are not above 2000; they inhabit two villages in the district of Peterwardein, and have retained their manners and language. The majority of the inhabitants are of the Greek not-united Church, in 450 parishes; next in number are the Roman Catholics, in 330 parishes. The united Greeks have 150 parishes; the Protestants (about 50,000 in all) are Calvinists, having 85 parishes, Unitarians 10, and Lutherans 4 parishes. 'All the inhabitants of the Military Frontier,' says Hassel, 'are endowed with admirable natural faculties, and, whether in the rude climate of the Carpathians, or the milder temperature of the plains, are distinguished for talent. But all these excellent gifts of nature are still buried, generally speaking, in profound slumber; and it is but lately that some efforts are perceived to call them into action. The government has done much to promote public instruction; but the number of schools is far too small, especially amongst the followers of the Greek Church; so that frequently there is not a single school in a tract of many leagues in extent.' This, it is true, was written twenty years ago; but it would seem that little progress has been made since that time, for the number of schools stated to exist in 1820 is quoted without alteration in the Austrian 'Encyclopædia' in 1838. The great variety of costume appears surprising to a stranger; for while persons in office and the ladies in the towns adopt the fashions of Vienna, each nation and tribe has its own costume, which in Croatia and some other parts has a striking resemblance to that of some countries of the East. Various and often unjust judgments have been passed on the character of these people: with some exceptions, of course, they may be described, according to Hassel, Blumenbach, and other writers, as a people of great natural talents, acute, docile, very patriotic, devotedly attached to the Imperial house, brave, frank, hospitable, fond of music and poetry, and possessing a great degree of national pride. Their domestic arrangements are founded on the patriarchal way of life, derived from remote ages, which the government has carefully maintained. All the branches of a family (called a house communion) live together, and several generations are found at the same time in one house. The head of the family, called the Goszpodar, exercises a kind of patriarchal authority, which all the members are bound to respect and obey. The males who are of age have however a vote in the discussion of all important family concerns. The mother, who is called Goszpodarieza, presides over the internal affairs, and superintends the female members of the family. The property of the family is in common, and no one is exempt from the duty of working. Each person who works has an equal share in the produce, but the Goszpodar and his wife have each a double portion. No member is allowed to have land or cattle of his own; but he may possess money and furniture. He who leaves the house without the consent of the elders and the regiment is reputed a deserter. Daughters who marry into another house have a smaller portion. Such a family often consists of 30, 40, and even 80 members. [PETERWARDEIN; SEMLIN.] (Von Hietzinger, *Statistik der Militärgrenze*, 1822; *Oesterreichische National Encyclopædie*, 1838; Hassel, vol. ii.; also Stein, Horschelmann, and other writers.)

MILITARY POSITIONS are the sites occupied by

armies either for the purpose of covering and defending certain tracts of country or preparatory to the commencement of offensive operations against an enemy.

A position is considered as advantageously chosen when it is on elevated ground; when it is not commanded by eminences within the range of artillery; and when, from the existence of natural obstacles, as rivers or marshes, on the wings, it is incapable of being turned, that is, the enemy cannot without making an extensive movement get to the rear of the army by which the position is occupied. In the event of such points of support being wanting, the position, whether it be a plain or an eminence, should have its flanks protected by villages, or by redoubts raised for the purpose; for the flanks being the weakest points of the line, since the troops there are only defended by their own fire, they particularly require to be strengthened by the impediments of the ground or by fortifications, in order that the enemy, in any attempt to turn the position, may be retarded till reinforcements can be brought up to oppose him.

The advantages possessed by an army on commanding ground consist in the troops being able to see the manœuvres of the enemy while their own are concealed; the fire also, being directed downwards, is more effective than that of the enemy, which is made upwards from a lower level. The existence of woods or hollow ways in front of a position is considered as an unfavourable circumstance, since an enemy might there place divisions or parties for the purpose of attacking the line by surprise; but, on the other hand, a wood in the rear, if it should not be such as to create an impediment to the passage of the troops through it, might become advantageous in the event of a retreat, as it would afford a temporary cover for the retiring columns. A village or even a single building on the ground occupied by the army may become the key of the position; and as, frequently, on the preservation of this point depends the possession of the field of battle, such point should be well supported by troops and artillery. At the battle of Coruña, in 1809, the village of Elvina was twice contested by the opposing armies; and on the field of Waterloo, the Châteaude Goumont was the object about which the action raged with the greatest violence. The highest point of ground, particularly if near the lines of operation (the roads leading to the magazines), may also constitute the key, and it is usually strengthened by one or more redoubts. It would evidently be advantageous if such key were near the centre of the line, because, on any change in the disposition of the latter, the key might still be retained, and if the wings are separated from each other, it might prevent either of them from being cut off by the enemy; whereas if situated at one extremity, it might, on a wheel of the army taking place, become so remote as to be incapable of being supported.

The elevated ground which constitutes the position should be able to contain all the troops who are to occupy it, but it should not much exceed the extent necessary for this purpose, lest, not being able to defend the whole, the army should be deprived of the advantages arising from a superiority of command, in consequence of the enemy gaining some part of the height.

However favourable a position may be with respect to the elevation of the ground, that circumstance will be of small value if the troops and artillery cannot be conveniently placed on it. It is indispensable that the ground afford ample room for the manœuvres of that species of troops in which the strength of the army chiefly lies; and at the same time it may be observed that, in making choice of a position, the ground in front should be as much as possible disadvantageous in that respect for the enemy. The Spanish General Cuesta is blamed for having, previously to the battle of Rio Seco in 1808, placed his army in such a situation that the ground before it was in the highest degree favourable for the action of the French cavalry, which was particularly numerous. Artillery should always be placed where it can act with most effect; and when the ground occupied by an army presents alternately salient and retired points along the front of the line, the batteries should be placed at all such points. At the former, in order that the lines of fire may effectually command the approaches by which the enemy's columns may advance; and at the latter, that they may defend the descending ground immediately in front of the others. Infantry may occupy any kind of ground, but should, if possible, always form a close line: it is usually placed between the batteries; and, if exposed to

a distant cannonade, the troops may be drawn up in a trench, the earth from which will serve to cover them without preventing them from marching out in line to meet the enemy. Cavalry must be posted on a level plain, over which it may advance with regularity when a charge is to be made; if compelled to act on broken ground, it is formed in small detachments behind the infantry, through whose intervals it may pass at proper opportunities. It may be observed that every disposition of an army for defence should correspond to that of the works which constitute a fortified place. The batteries at the advanced points of the line serve a purpose similar to that of the guns in the flanks of bastions; and the intermediate line of troops forms a sort of curtain.

In the choice of positions for offensive operations, such should be taken as have no rivers or broken ground in front; since these would impede the contemplated movements towards the enemy: small inequalities, behind which infantry or cavalry may be concealed, are however advantageous, as they afford the means of occasionally making attacks by surprise. On the other hand, when an army is on the defensive, the front as well as the wings should be protected by every obstacle to the progress of the enemy which nature may present or art can devise: among those afforded by the latter may be mentioned the blocking up of roads by abatis or traverses; preparing countermines, by which, on the enemy's advance, the roads may be destroyed; rendering fords impassable and even forming inundations by constructing dams across the streams. It should be observed however that when a defensive position is covered by a river, the line of troops should be at 800 or 1000 yards in rear of the latter, in order that sufficient space may be afforded for the troops to act against the enemy in the event of his forcing a passage across; and, in all cases, every obstacle in the way of a free communication within the position ought to be removed, that the troops may easily succour each other when attacked. Whatever be the nature of the obstacles opposed to the enemy, they should be within the range of the artillery of the line; and then the position may be considered as impregnable, since an enemy would find it scarcely possible either to form or deploy his columns of attack on broken ground and under a destructive cannonade. Good roads, on the other hand, should exist, or should be formed, in the rear, both to facilitate the arrival of supplies from the magazines or dépôts, and to favour a retreat, should the latter step become necessary. An army always retires in disorder under the fire of the enemy, and its danger is greatly increased when the retrograde movement is embarrassed by walls, ravines, streams, or other impediments; the divisions then become separated from each other, and some of them are generally cut off by the enemy before they can be supported. It would be advantageous that the ground in rear should command that of the position itself; for then the army, in retreating, would obtain a superiority of elevation over the pursuing enemy; and it might even have an opportunity of renewing the action with a prospect of success.

A knowledge of the art of choosing military positions is an important qualification in the staff-officers of an army: and these officers should continually exercise themselves in forming correct judgments concerning the fitness of ground for such positions. They should be able to ascertain at once, by the eye, its extent and the stations it may afford for troops of the different arms, so that those of all kinds may act with the greatest effect and duly support each other; and, consequently, they should be able to determine the order of battle which is the most advantageous for the ground to be occupied. They are also to judge of the facilities which the roads may present for an advance or a retreat, or for the conveyance of supplies from the magazines; and, finally, of the obstacles which the ground in front may oppose to the movements of the enemy. The power of readily appreciating the character of ground in all these respects is what is called, by foreign writers, the military coup-d'œil; and this can only be acquired by a profound knowledge of the tactics of war joined to much experience in the practice of executing military surveys, and of contemplating the appearance of ground from all possible points of view. These points being the supposed stations of the enemy, the staff-officer should accustom himself to observe from thence how the latter might make his attack; for then only can he judge in what manner an attack ought to be opposed; that is, what disposition of troops and artil-

lery would be the most favourable for resisting it when made. Continual meditation, from his youth, on the subjects above mentioned is stated by Livy to have distinguished the Achæan general Philopœmen, who was thus always prepared to avail himself of the advantages of ground in the disposition of troops for action.

MILITIA. The body of soldiers raised for the defence of a nation may be called the militia of that nation; but in Great Britain and Ireland the term is applied particularly to those men who are chosen by ballot to serve for a certain number of years within the limits of these realms. The regulations of the militia service differ widely from those of the conscription on the Continent; since under the latter the troops become members of the regular army, and may be marched beyond the frontiers of the state; whereas the militia is enrolled only for home service, and may be said to constitute a domestic guard. Nothing corresponding to a modern militia can be said to have existed among the ancients. In the Grecian states every citizen was a soldier; and every person, between certain ages, in the city and in the provinces, was obliged to serve in the Roman armies wherever they might be employed.

The military force of this country in the time of the Saxons was formed by a species of militia, and every five hides of land were charged with the equipment of a man for the service. The ceorles, or peasants, were enrolled in bodies and placed under the command of the Ealdermen or chiefs, who were elected by the people in the folk-motes. After the Norman conquest of the country the proprietors of land were compelled, by providing men and arms in proportion to their estates, to contribute to the defence of the realm in the event of a threatened invasion. The troops were raised under the authority of *commissions of array*, which were issued by the crown; and the command was sometimes vested in the persons to whom the commissions were granted; though frequently the high constables, or the sheriffs of the counties, commanded in their own districts. This militia seems, at first, to have been liable to be marched to any part of the kingdom at pleasure, but in the reign of Edward III. it was decreed by a statute that no man thus raised should be sent out of his county, except in times of public danger. From the reign of Philip and Mary the lords-lieutenants have had the charge, under the sovereign, of raising the militia in their respective counties.

Charles I. having, by the 'Petition of Right,' been deprived of the power of maintaining a disposable body of troops in the country, found himself, in 1641, unable to suppress the rebellion then raging in Ireland; and was in consequence induced to commit the charge of restoring peace to the care of the parliament. The latter immediately availed itself of the circumstance to get into its own hands all the military force of the nation; and in the following year the two houses passed a bill in which it was decreed that the power over the militia, and also the command of all forts, castles, and garrisons, should be vested in certain commissioners in whom they could confide. The king having refused his assent to the bill, the parliament made a declaration that it was necessary to put the nation in a posture of defence, and immediately issued orders to muster the militia; on the other hand, the king issued commissions of array for a like purpose to some of the nobility, and thus commenced that war which desolated the country for several years.

When Charles II. ascended the throne, the national militia was re-established on its former footing, and the chief command was vested in the king. The lords-lieutenants of counties were immediately subordinate to the sovereign, and granted commissions (subject however to the king's approbation) to the field and regimental officers who commanded under them. New regulations respecting the amount of property which rendered persons liable to the charge of providing men and arms were then established; and at that time no one who had less than 200*l.* yearly income or less than 2400*l.* in goods or money could be compelled to furnish a foot soldier; nor could one who did not possess 500*l.* per annum or an estate worth 6000*l.* be made to provide a man for the cavalry. Persons having less property were required, according to their means, to contribute towards finding a foot or a horse soldier. The militia was then mustered and trained, by regiments, once a year and during four days; but the men were mustered and trained, by companies, four times in the year, and during two days each

time. At the periods of mustering, every man was obliged to provide himself with his own ammunition.

These regulations, being found to be expensive, at length ceased to be observed, and the trainings of the militia were discontinued in every part of the realm except the city of London. In 1756, under an apprehension that the country was about to be invaded by a French army, considerable bodies of Hanoverian and Hessian troops were brought over for its defence; the spirit of the nation revolted however at the disgrace of being indebted to foreign mercenaries for protection; and these troops being sent back to the Continent, a national militia was again raised and organised under the sanction of an act of parliament in the 30th year of George II. The measure was generally popular, though it did not meet with universal approbation; and there were many persons who maintained the opinion that, for want of military knowledge and habits, this species of force could not be relied on in the event of its being called into active service. Experience has however shown that such an opinion is quite destitute of foundation; and it was soon afterwards admitted that, when well disciplined, these constitutional battalions rivalled those of the regular troops in the performance of all military evolutions. It may be observed here, that the greater part of the 16,000 British troops who gained the battle of Talavera were men drafted from the militia regiments at home; and so recently had they joined the army in Spain, that in the action many of them bore on their accoutrements the numbers of their former corps. (Napier, vol. ii.)

The militia laws were repealed in the 2nd year of George III., when a new act regulating the service of this force was passed; and in the 26th George III. all the previously existing statutes relating to the force were formed into one law. New regulations however were made by acts passed in the 42nd, 51st, and 52nd years of the same reign. The militia of the kingdom is now embodied under general officers, and is subject to the provisions of the mutiny act, or articles of war. The king is empowered to employ it in any part of the United Kingdom, but not out of it. The militia of Great Britain may serve in Ireland, and that of Ireland in Great Britain: the period of service for each, out of the island to which it belongs, being at most two years. When called into active service the officers rank with those of an equal grade in the regular army, but as the juniors of each grade, and they may receive promotion for meritorious services during a rebellion or an invasion; but no officer of militia can serve on a court-martial at the trial of an officer or soldier of the regular troops.

All persons not labouring under bodily infirmity and not specially excepted, are liable to be chosen for private militia men and to serve either personally or by substitute. The persons excepted are—peers of the realm; commissioned and non-commissioned officers and privates serving in the regular forces; half-pay officers of the navy, army, and marines, and commissioned officers who have served four years in the militia; members of corps of yeomanry and volunteers, and privates serving in the local militia; seamen and persons doing duty in the royal docks, at the gun-wharfs, and powder magazines; also persons employed under the direction of the Board of Ordnance; resident members of the two universities; clergymen of the Established church; also Protestant dissenting preachers, provided they take the oaths of allegiance and supremacy, and exercise no other occupation, or only that of schoolmaster; constables or other peace-officers; articulated clerks; apprentices; free watermen on the Thames; poor men having more than three legitimate children, and persons above 45 years of age. To alleviate the distress of a poor man, when drawn for the militia, and who has provided a substitute, the churchwardens of the parish are bound to return to him a sum not exceeding 5*l.*, or half the current price of a substitute. No one having served personally, or by substitute, during three years in the militia, can be obliged to serve again till it comes to his turn by rotation; but if a man has served as a substitute for another, this does not exonerate him from serving again if chosen by the ballot.

The militia is trained and exercised by battalions or regiments twice in a year, and during fourteen days each time, or once in a year for twenty-eight days, at the discretion of the lords-lieutenants or their deputies.

The supplementary militia is an additional body of men which was first raised in 1793, for the defence of the country at that juncture. It is still continued to be raised when

the necessities of the state require it, and it is subject to the same regulations as the ordinary militia. The local militia was a body raised in 1809, for the purpose of replacing, in certain districts, the corps of volunteers. By the 52nd George III., this force may be marched to any part of Great Britain in the event of a rebellion or an invasion, and it may be kept embodied till six months after the former is terminated or the latter repelled. Persons enrolled in the local militia cannot be compelled to serve in the regular militia till one year after their period of service in the former has expired.

The whole amount of the several militia forces in England alone exceeds 200,000 men; and during the late war, when an invasion of the country was apprehended, the force which might have been assembled in arms amounted to more than twice that number of men.

In France a militia was first raised from the provinces during the reign of Louis XIV.; but the several corps were disbanded after the peace of Ryswick. In 1726 was organised a force of the like kind, consisting of men chosen by lot from the towns and villages, and held in readiness to be assembled when required: and in 1778 these provincial troops were formed into 106 battalions. Since the great Revolution, the National Guard may be said to constitute the militia of France.

In the United States of America, by an act passed in 1792, the principal provisions of which are still in force, all able-bodied white male citizens between the ages of eighteen and forty-five, with certain exceptions, are enrolled in the militia; and when drafts are to be made for active service, the individuals are selected by ballot as in this country. The persons excepted are the executive, judicial, and representative officers of the Union, those who are employed in the post-office department, &c.; and, in some of the states, persons are exempted who have scruples of conscience against bearing arms. The president has the power of calling out the militia of the states; and, when on active service, it is subject to the same rules and articles of war as the regular troops, but courts-martial for the trial of military offenders are composed of militia officers only.

A national militia is an institution of the highest utility to a state; the men being engaged in military occupations only so long as may be necessary for becoming qualified to serve as soldiers when called upon to take the field, and being at all other times employed in labours subservient to the practice of the useful arts. They thus possess the united characters of defenders of their country and of contributors to its prosperity, while they remain connected in social union with their fellow-citizens, and are interested, like them, in the support of the laws and in the preservation of good government. It is in some respects otherwise with the soldiers of a regular army, who, devoted exclusively to the profession of arms, and though their services are indispensable in the prosecution of foreign wars, have few feelings in common with the civil portion of the community; and who, except in a nation like Great Britain, where the military power is duly subordinated to the civil magistrate, might, under the influence of an ambitious chief, become dangerous to the liberty of their country.

MILIZIA, FRANCESCO. According to the autobiographical sketch which he has left us, Milizia was born at Oria, a small town of the province of Otranto, in the kingdom of Naples, in 1725, and was of a noble and wealthy family. When nine years old, he was placed under the charge of his maternal uncle, who practised medicine at Padua. With him he remained about seven years, when he ran away from him and joined his father, who was then at Rome, and who sent him to Naples, where he studied logic and metaphysics under the celebrated Genovesi, and physics and geometry under the Padre Orlandi. He was more anxious however to study the world, and set out from Naples with the intention of going to France, but his finances would carry him no farther than Leghorn. After this he was obliged to content himself with leading a half studious, half indolent life at Oria. At the age of twenty-five, he married a young lady of family at Gallipoli, and having obtained a handsome allowance from his father, went to Rome, where he ultimately settled with his wife, in 1761. It was here that he began to apply himself diligently to the study of architecture, and published his *Lives of the Architects*, or *Vite degli Architetti piu celebri*, in 1768, which was followed by his treatise *Del Teatro*, in 1772, a production that excited so much scandal on account of

P C, No. 939.

certain observations in it, that it was suppressed by withdrawing all the copies; yet was soon afterwards republished at Venice. His *Principles of Civil Architecture*, first published in 3 vols. 8vo., in 1781, and considerably improved in the third edition at Bassano, 1785, greatly extended his literary reputation, being, at the time of its appearance, almost the first attempt to base the art on rational principles, and to expose the pedantry with which it had been taught. It is moreover written in an attractive style, and is seasoned with not a little mordacity and causticity in some of the remarks. On this latter account, while it was admired by young students, it was censured by many more advanced professors, who charged the author with speaking too freely of many eminent names, with attacking authorities, and propounding his own views without regard to the example of others. His *Arte di vedere nelle Belle Arti*, in which he showed himself a strong partisan of Mengs, is another work written with great eloquence, and with equal freedom of opinion, impugning Michael Angelo, among others, with unsparing severity. He also published a work entitled *Roma delle Belle Arti di Disegno*, and his *Dizionario delle Belle Arti*, which latter, first printed at Bassano, in 1797, 2 vols. 8vo., is chiefly a translation from the *Encyclopédie Méthodique*. After this, disgusted at the attacks levelled against his *Roma*, he not only desisted from publishing the second and third parts which he had proposed of that work, but abandoned the fine arts, and took up the study of natural history. He died at Rome, in March, 1798.

Milizia had for a short time held the appointment of superintendent of the buildings in the Ecclesiastical States belonging to the king of the Two Sicilies, but he resigned it in 1786, not caring to have any such responsibility or tie upon him. His *Lettere inedite*, addressed to the Count Sangiovanni, and first published at Paris, in 1827, serve to portray his disposition, and, without the testimony of his other writings, to convince us that he abhorred pedantry and dogmatism, false enthusiasm, and quackery. They abound with very free remarks on persons, and are seasoned with much caustic humour. An English translation of his *Lives of the Architects* appeared in 2 vols. 8vo. in 1826, but besides being badly executed and full of gross errors of the press, it does not supply those names which Milizia omitted, nor the numerous other names that ought now to find their place in such a work.

MILK is an opaque fluid, secreted by the mammary glands of the females of the animals belonging to the class *Mammalia*, and adapted to the nourishment of their young offspring. It is of a specific gravity somewhat greater than that of distilled water, and possesses a peculiar odour, which is due to several acids. It consists, in addition to the watery portion, serum, &c., of globular particles, which are not more than half the size of the globules of human blood, having a diameter of about one ten-thousandth of an inch. They are composed of a fatty matter (butter) and a coagulable substance, which in many points resembles albumen, termed *caseum*.

The globules are specifically lighter than the fluid in which they are suspended, and easily ascend to the top when the milk is allowed to stand. This constitutes the cream, and consists of the butter, with some caseum and a portion of serum. By agitation, such as is effected by the various modes of churning, the fatty globules unite into a mass (butter), leaving the buttermilk, which consists of caseum and serum.

Milk from which the supernatant fluid, or cream, has been removed is termed skim-milk, and still retains a considerable quantity of coagulable or caseous matter, which may be separated from the serum, or whey, by means of a rennet or any acid. This coagulated portion constitutes the curd, and is the basis of cheese. If a rennet be used, and all the portion coagulated by its means be separated, the addition of vinegar causes some of what remains to coagulate; and this has been termed *zieger* by Schubler, but it is not certain that it differs from caseum. What remains after both these coagulated principles have been removed is the whey, which contains sugar of milk, some azotized substance (perhaps osmazome), lactic acid, and various salts.

The different constituents of milk, and the differences in the relative proportions of them in some of the common domestic animals, will be best seen in the following tables drawn up by Mr. Pereira:—

Milk	Cream	{	Butter	{	Fatty Matter, solid at ordinary temperatures	By saponification, yielding Butyric, Caproic, Capric, Margaric, and Oleic Acids, and	{	Stearine.				
									Liquid Fatty Matter	Glycerine	Butyrine.	
	Buttermilk	{	By saponification, yielding no Butyric, Caproic, nor Capric Acids	{	Oleic.							
						Caseum.	Serum.					
	Skim-Milk	{	Matters which are coagulable	{	by Rennet			not by Rennet, but by Acetic Acid	{	Caseum or Curd.		
						Azotized Matter	Lactic Acid.				{	Zieger.
	Serum or Whey	{	Salts	{	Soluble in Alcohol	{	Lactates of Potash, Soda, Ammonia, Lime, and Magnesia.					
								Soluble in Water, not in Alcohol	{	Chlorides of Potassium and Sodium.		
	Insoluble in Water	{	Phosphate of Potash.									
{				Phosphate of Potash and Soda.								
	{	Phosphates of Lime, Magnesia, and Iron.										

100 Parts of the Milk of the	Cream.	Butter or Fatty Matter.	Caseum.	Sugar of Milk.	Total Butter, Caseum, and Sugar of Milk.

				(only 3.7 according to Young)	

From these analyses it would appear that milk is a compound fluid, chiefly consisting of oleaginous and albuminous materials, with different salts.

According to Dr. Prout, 'albuminous and oleaginous principles may be considered already fitted for the purposes of the animal economy, without undergoing any essential change in their composition.' And thus, by the action of the organs of the parent, the food is brought into a state very favourable for its assimilation in the body of the young, without taxing severely the digestive organs of the latter. The salts present in the milk serve also important uses, especially the phosphate of lime by consolidating the bones which, at the time of birth, are soft and cartilaginous. The period when lactation in the human offspring should cease must vary with the vigour and progress of development of the infant; but in general nine months is the proper time for suckling, and its continuance beyond that period is injurious both to parent and child.

The milk of cows or other animals is extensively used as the food even of adults, and, though insufficient alone, is a most valuable ingredient of diet. It is often enjoined as the food of invalids, especially of persons who have a tendency to consumption.

Milk is also used as an antidote in cases of poisoning by some metallic salts, such as corrosive sublimate, perchloride of tin, sulphate of copper, &c.

Though cheese is in general difficult of digestion, fresh-pressed curd is often found to suit the stomach of persons affected with disease of that organ. (See Abercrombie, *On Diseases of the Stomach*.)

Milk may be brought to a dry state, and powdered, in which condition it keeps for a length of time; and by dissolving it in tepid water an artificial milk may be formed, capable of being used at sea, particularly for children during long voyages.

(See Mr. Pereira's 'Lectures' in the *Medical Gazette*.)
MILKY WAY. It is desirable, in describing astronomical objects; to keep as close as possible to the words of those who are accustomed to the sight and description of such things. Two passages in Sir John Herschel's 'Astronomy' (pp. 163, 375, 376, Lardner's *Cyclopædia*, No. 43) will describe the Milky Way, and the theory of it, by Sir William Herschel, with excellent brevity and distinctness.

* Many popular works on astronomy contain nothing but descriptions of descriptions, in which want of absolute plagiarism is no merit, but the reverse. We recommend the work cited to those of our readers who are not already acquainted with it, as that of an actual observer whose felicity of description is very notorious among those who are in the habit of viewing the celestial bodies.

There are not wanting *natural* districts in the heavens, which offer great peculiarities of character, and strike every observer: such is the Milky Way, that great luminous band which stretches, every evening, all across the sky, from horizon to horizon, and which, when traced with diligence, and mapped down, is found to form a zone, completely encircling the whole sphere, almost in a great circle, which is neither an *hour* circle nor coincident with any other of our astronomical *grammata*. It is divided in one part of its course, sending off a kind of branch, which unites again with the main body after remaining distinct for about 150°. This remarkable belt has maintained, from the earliest ages, the same relative situation among the stars; and when examined through powerful telescopes, is found (wonderful to relate!) to consist entirely of stars scattered by millions, like glittering dust on the black ground of the general heavens.

If the comparison of the apparent magnitudes of the stars with their numbers leads to no general conclusion, it is otherwise when we view them in connection with their local distribution over the heavens. If indeed we confine ourselves to the three or four brightest classes, we shall find them distributed with tolerable impartiality over the sphere; but if we take in the whole amount visible to the naked eye, we shall perceive a great and rapid increase of number as we approach the borders of the Milky Way. And when we come to telescopic magnitudes, or stars of so small a magnitude as to be invisible except through a telescope we find them crowded, beyond imagination, along the extent of that circle, and of the branch which it sends off from it; so that in fact its whole light is composed of nothing but stars, whose average magnitude may be stated at about the tenth or eleventh.

These phenomena agree with the supposition that the stars of our firmament, instead of being scattered in all directions indefinitely through space, form a stratum, of which the thickness is small, in comparison with its length and breadth; and in which the earth occupies a place somewhere about the middle of its thickness, and near the point where it subdivides into two principal laminae, inclined at a small angle to each other. For it is certain that to an eye so situated, the apparent density of the stars, supposing them pretty equally scattered through the space they occupy, would be least in a direction of the visual ray (as S A) perpendicular to the lamina, and greatest in that of its breadth, as S B, S C, S D; increasing rapidly in passing from one to the other direction, just as we see a slight haze in the atmosphere thickening into a decided fog-bank near the horizon, by the rapid increase of the mere length of the visual ray. Accordingly, such is the view of the construc-

tion of the starry firmament taken by Sir William Herschel, whose powerful telescopes have effected a complete analysis of this wonderful zone, and demonstrated the fact of its consisting entirely of stars. So crowded are they in some parts of it, that by counting the stars in a single field of his telescope, he was led to conclude that 50,000 had passed under his review in a zone two degrees in breadth, during a single hour's observation. The immense distance at which the remoter regions must be situated, will sufficiently account for the vast predominance of small magnitudes which are observed in it. [HERSCHEL; NEBULÆ.] But to the above it must be added, that the fifty thousand stars thus men-

tioned as contained in a zone of 15° by 2° include only those which could be steadily seen and distinctly numbered; besides which, twice as many more were suspected, of which only occasional glimpses could be got for want of sufficient light.

The Milky Way may be described in general terms as extending three or four degrees on each side of a great circle inclined at an angle of about 60° to the ecliptic, which it cuts in the northern hemisphere between the horns of Taurus and the feet of Gemini, and in the southern hemisphere between Sagittarius and Scorpio. Beginning with the part nearest to the North Pole, it nearly covers Cassiopea and Perseus, and then, becoming thinner, passes through Auriga, between Taurus and Gemini, and near the back of Canis Major through Argo. It then narrows considerably, and passing under the hind feet of Centaurus, widens again near Ara. A little above the last constellation, and before it again meets the ecliptic, it divides into the two streams above mentioned, which contain between them a long thin strip passing through part of Scorpio, Serpens, Aquila, Vulpecula, and Cygnus. In Cygnus the streams reunite, but immediately separate again, finally reuniting higher up in the same constellation, from whence the main stream reaches Cassiopea, &c.

The Milky Way was called by the Greeks *γαλαξίας*, or *κύκλος γαλακτικός* (whence our word *Galaxy*), and by the Romans *Orbis lacteus*. The mythology of the former people on the subject is as edifying as usual: Hyginus fixes on Eratosthenes the most common story, namely, that the Galaxy arose from the milk of Juno, who pushed Hercules away from her breast (where he had been placed by Jupiter) on learning that he was the son of Maia. Nor does the above accurate writer forget to mention that others held the appearance to have arisen from young master Hercules having been a greedy child, and having filled his mouth too full. Others thought that the whole was not milk, but ears of corn which Isis dropped in her flight from Typhon. Another fable, mentioned by Plato, makes the Milky Way to be a broad causeway through the heavens for gods and heroes to walk upon; another, that it is the part of the heaven which was singed when the horses of the sun ran away with Phaeton. These stories are a proper prelude to the speculations of the philosophers which followed. Some of the Pythagoreans are reported to have supposed the Milky Way to be an old and disused path of the sun, out of which, some said, he was frightened by the banquet of Thyestes; others, a reflexion from the sun. Anaxagoras is said to have thought it was the shadow of the earth: Aristotle supposed it to be sublunary, and to consist of exhalations, of the same matter as comets. Posidonius took it for a band of fire; Theophrastus for a solid and luminous band, joining together the two hemispheres; while Diodorus thought it was celestial fire shining through the clefts of the solid heavens. Democritus hit the true explanation, namely, that it is a congeries of little stars too small to be separately seen—an opinion which both Plutarch (*De Placit. Philos.*, l. iii., c. 1) and Manilius mention. Shortly after the invention of the telescope, Galileo announced that he had resolved the whole of the Milky Way into stars. 'Est enim *Galaxia* nihil aliud quam *innumerarum stellarum coacervatim consitarum congeries*: in quacunque enim regionem illius perspicillum dirigas, statim stellarum ingens frequentia sese in conspectum profert quarum complures satis magnæ et valde conspicuæ videntur, sed exiguarum multitudo prorsus inexplorabilis est.' (*Nuncius Sideris*.) It is however not easy to suppose that Galileo's resolution of the Milky Way was complete; and we may here see how necessary is attention to minute description. When Sir J. Herschel, in the paragraph cited above, states the stars to appear 'like glittering dust on the black ground of the general heavens,' we know that, if the observer can be depended upon, he has completely resolved the continuous light in question: but if he only says, with Galileo, that he detected innumerable stars, we are only sure that he has distinguished the nearer stars, and may suppose that the more distant ones still formed a Milky Way behind them. That this must have been the case with Galileo (whose telescopes would never distinctly show Saturn's ring) may be confidently asserted. It must also be remembered that Galileo had completely resolved several nebulae, and might easily have completed his assertion as to the Milky Way from analogy. Kepler ('*Dioptr. Pref.*') describes this resolution in a way which will be some guide as to its character:

'Nebulosa stella ostendit, ut in *Via Lactea*, duas, tres, vel quatuor clarissimas stellas in arctissimo spatio collocatas;' that is, two, three, or four stars were seen in the smallest space: this may very well correspond to Sir W. Herschel's estimate of 50,000 in the zone above mentioned, without the necessity of supposing that those stars were seen, which the forty-foot reflector would only show by glimpses. Sir W. Herschel counted seventy-nine stars, on the average, in a field of fifteen minutes in diameter, showing about as much of the heavens as is covered by one-fourth part of the moon. If, which may be suspected, the 'arctissimum spatium' of Kepler meant the field of his telescope, the resolution thus obtained would not quite justify the conclusion, except as a probable deduction; the real and necessary inference would only have been, that stars invisible to the naked eye exist in every part of the Milky Way in considerable numbers.

MILL, JOHN, was born at Shap, in Westmoreland, about 1645. In 1661 he entered as servitor at Queen's College, Oxford, took his degree of B.A. in 1666, of M.A. 1669, and was shortly afterwards chosen a fellow and tutor of his college. In 1676 he was made chaplain to Dr. Lamplugh, bishop of Exeter, and in 1681 obtained the rectory of Blechingdon, in Oxfordshire, and was appointed chaplain to Charles II. In 1685 he was appointed principal of St. Edmund's Hall, which office he held till his death, which happened June 23rd, 1707.

Mill is known by his valuable edition of the Greek Testament, which was published only fourteen days before his death, with the following title: 'Novum Testamentum Græcum, cum Lectionibus variantibus, MSS. Exemplarium, Versionum, Editionum, SS. Patrum et Scriptorum Ecclesiasticorum, et in eadem Notis.' This edition, which was the labour of thirty years, was originally begun by the advice of Dr. Fell, bishop of Oxford, and reflects the greatest credit on the diligence and critical acumen of its learned editor. He inserted the various readings that had been previously collected, procured extracts from several then uncollected MSS., and added many readings from the ancient versions and the writings of the fathers. Mill however made no change in the text, which was merely a reprint of Robert Stephens's edition of 1550. These various readings, which amounted to more than 30,000, were attacked by Dr. Whitby, in 1710, in a work entitled 'Examen Variantium Lectionum Johannis Millii,' in which he maintained that a collection of so many various readings tended to unsettle the text of the New Testament, and to introduce doubt and uncertainty into the whole system of biblical interpretation. Dr. Whitby's arguments were applied by Antony Collins, in his 'Discourse on Free-thinking,' against the authority of the New Testament; whose work was answered by Bentley, a personal friend of Mill's, under the signature of Phileleutherus Lipsiensis.

The edition of the Chronicle of Malala, published at Oxford, in 1697, which is frequently said to have been edited by Mill [BENTLEY], was merely published under his superintendence, since the printing of the work was finished under the revision of Chilnead. [MALALA.]

MILL, JAMES, was born at Montrose, on the 6th of April, 1773. He is said to have received the early part of his education at the grammar-school of Montrose. However this may be, he was, subsequently at least, educated in the house of Sir John Stuart (originally Belcher), who was for a long time member of parliament for Kincardineshire. Mr. Mill was sent to the university of Edinburgh, where he was educated for the church and where he distinguished himself as a Greek scholar. Metaphysical and ethical philosophy also occupied a great part of his time at the university. He was a favourite of Dalzel, the then Greek professor in Edinburgh, who recommended him as a tutor to the Marquis of Tweeddale. He was licensed to preach about 1798. By the advice of a friend he changed his views, and in 1800 accompanied Sir John Stuart to London, where he settled. He became editor of 'The Literary Journal,' a review, which supported him for some time, but was discontinued in consequence of the smallness of the sale. Mr. Macdiarmid, and Dr. T. Thomson, professor of chemistry in the university of Glasgow, were the chief contributors. He afterwards employed much of his time in writing for periodical publications; and for several years he was an occasional contributor to the 'Edinburgh Review.' He married soon after he had settled in London. His acquaintance with Mr. Bentham commenced at an early period of his residence in the metropolis.

His 'History of British India' was commenced about 1806, but being a work of great labour, and the author being obliged to devote a considerable portion of his time to other avocations, it was not published till the winter of 1817-18. It is perhaps no very high praise of this work to say that it is not only the best history of British India, but the only single work calculated to convey to the general reader any clear and connected view of India and Anglo-Indian affairs. But it possesses higher claims than these. It is admitted by some of the most eminent of those who have administered Indian affairs for the last ten years, that Mr. Mill's work was the beginning of sound thinking on the subject of India; and the measures of government in that country are stated by those who have the best means of knowing, to be now bearing every year more and more the impress of his views. The style of Mr. Mill's history has been represented by some as dry and unattractive. Mr. Mill certainly does not deal much in rhetorical ornament, at least in what is usually considered such by modern writers, for his style reminds us more of the nervous simplicity and terseness of some of the ancient masters of the difficult art of writing, than that of any modern except Hobbes. The reader who is really in search of a meaning will find it in the writings of Mr. Mill with far less labour than where it is to be sought for in a crowd of unapt and unnecessary words. These remarks may be said to be applicable rather to Mr. Mill's philosophical than to his narrative style. But although not possessing narrative powers of the same kind as Sir Walter Scott or even David Hume, there are passages of Mr. Mill's history which will interest many readers as much as the most spirit-stirring romances; for instance, his account of some of the actions of Clive, and of Cornwallis's night attack upon the outworks of Seringapatam. His narrative of military operations is good; clearness, in which Mr. Mill excels, being the principal quality required. And some of his characters, that of Clive in particular, are drawn in a few bold and forcible lines, which engrave them on the mind of the reader.

In consequence of the ability and knowledge of the subject displayed in his history, and although he had in some parts of it freely censured the conduct of the East India Company, the Court of Directors, in the spring of 1819, introduced him into their home-establishment, and intrusted to him the chief conduct of their correspondence with India in the revenue branch of administration. He afterwards rose, in the course of promotion, to be head of the department in the India House of correspondence with India.

About three years before his appointment to his office in the India House, Mr. Mill became a contributor to the 'Supplement to the Encyclopædia Britannica,' his principal contributions to which were the articles on Government, Education, Jurisprudence, Law of Nations, Liberty of the Press, Colonies, and Prison Discipline. These essays were reprinted in a separate form, and are probably the best known of Mr. Mill's productions. They exhibit great powers both of analysis and ratiocination, and have produced, we believe, more marked effects than any other, not only of the works of Mr. Mill, but of any other writer of this age on such subjects, on the minds of his contemporaries.

His 'Elements of Political Economy,' whatever may be its merits or demerits, and it made no pretensions to originality, published in 1821-2, has at least the very great merit of being written with his usual clearness and precision of language.

In 1829 he published his 'Analysis of the Phenomena of the Human Mind,' a work on which he bestowed more of the labour of thought than on any other of his productions. In this work Mr. Mill has attempted to resolve all the powers of the human mind into a very small number of simple elements. From an examination of a number of the more complicated cases of consciousness, he arrives at the conclusion that they all resolve themselves into three simple elements—sensations, ideas, and the train of ideas. He thus explains what he means by the terms *sensations* and *ideas*. 'We have two classes of feeling: one, that which exists when the object of sense is present; another, that which exists after the object of sense has ceased to be present. The one class of feelings I call sensations; the other class of feelings I call ideas.' (*Analysis of the Phenomena of the Human Mind*, vol. i., p. 41.) Mr. Mill begins with the simpler, and thence proceeds to the exposition of the more complex phenomena. 'The feelings,' he says, 'which we have through the external senses are the most simple, at

least the most familiar, of the mental phenomena. Hence the propriety of commencing with this class of our feelings.' (*Analysis*, vol. i., p. 1.) Accordingly, he begins with sensation, under which head he ranges the feelings which we have by the five senses—smell, taste, hearing, touch, and sight. 6, Sensations of disorganization, of the approach to disorganization, in any part of the body. 7, Muscular sensations, or those feelings which accompany the action of the muscles. 8, Sensations in the alimentary canal. He next proceeds to ideas, or the copies or images of sensations. He then treats of ideas put together or associated in trains, and of the order of their association and the causes of that order. Before proceeding to the exposition of the more complex ideas or clusters of ideas, he finds it necessary to explain the process of naming, or language; that process by which the sensations and ideas of one man are communicated to another, and by which likewise a record is preserved of sensations and ideas after they are passed. He then treats of consciousness and conception, which philosophers, he says, have erroneously created into what they called powers of the mind: whereas, he says, consciousness is merely a name applied to sensations, and to ideas whether simple or complex; to all the feelings of our sentient nature: and conception a name applied only to ideas, and to ideas only in a state of combination. But consciousness may surely be said to be the power of having sensations and ideas; and conception the power of having ideas in a state of combination.—In this sense, which is not at variance with Mr. Mill's explanation of them, both consciousness and conception may be called powers of the mind.

Again, imagination, he says, is the name of a *train* of ideas. 'I am said to have an imagination, when I have a train of ideas; and when I am said to imagine, I have the same thing; nor is there any train of ideas to which the term imagination may not be applied.'

'There is great diversity of trains. Not only has the same individual an endless variety of trains, but a different character belongs to the whole series of trains which pass through the minds of different individuals or classes of individuals. The different pursuits in which the several classes of men are engaged render particular trains of ideas more common to them than other trains. One man is a merchant, and trains respecting the goods in which he buys and those in which he sells are habitual in his mind. Another man is a lawyer, and ideas of clients and fees, and judges and witnesses, and legal instruments and points of contestation, and the practice of his court, are habitually passing in his mind. Ideas of another kind occupy the mind of the physician; of another kind still the mind of the warrior. The statesman is occupied with a train different from that of any of the classes that have been mentioned, and one statesman with a very different train from another, according as his mind is running upon expedients which may serve the purpose of the day, or arrangement which may secure the happiness of the population from generation to generation. A peculiar character belongs to the train which habitually occupies the mind of the mathematician. The mind of the metaphysician is also occupied by a train distinguished from that of other classes. And there is one man yet to be mentioned, the poet, the peculiarity of whose trains has been a subject of particular observation. To such a degree indeed have the trains of the poet been singled out for distinction, that the word imagination, in a more restricted sense, is appropriated to them. We do not call the trains of the lawyer, or the trains of the merchant, imagination. We do not speak of them as imagining when they are revolving each the ideas which belong to his peculiar occupation; it is only to the poet that the epithet of imagining is applied. His train or trains analogous to his are those which receive the name of imagination.' (Vol. i., p. 179.)

In some parts of his book Mr. Mill has, we think, been led into error, in part probably by carrying his notion of association as an explanation of these phenomena too far. Thus in the chapter on classification, after very ably showing how long men had been led away by mere jargon from the real nature and object of classification, he says, 'Man first becomes acquainted with individuals. He first names individuals. But individuals are innumerable; and he cannot have innumerable names. He must make one name serve for many individuals.' After then alluding to the case of 'synchronous sensations so concentered by constant conjunction as to appear, though numerous, only one; of

which the ideas of sensible objects, a rose, a plough, a house, a ship, are examples—he thus proceeds: ‘It is easy to see wherein the present case agrees with and wherein it differs from those familiar cases. The word man, we shall say, is first applied to an individual; it is first associated with the idea of that individual, and acquires the power of calling up the idea of him; it is next applied to another individual, and acquires the power of calling up the idea of him; so of another, and another, till it has become associated with an indefinite number, and has acquired the power of calling up an indefinite number of those ideas indifferently. What happens? It does call up an indefinite number of the ideas of individuals as often as it occurs; and calling them up in close connection, it forms them into a species of complex idea.’ (Vol. i., p. 204.) Mr. Mill then says there can be no difficulty in admitting this, ‘because it is an acknowledged fact.’ Mr. Mill himself furnishes what he considers the reason, for he says, ‘It is also a fact that when an idea becomes to a certain degree complex from the multiplicity of the ideas it comprehends, it is of necessity indistinct. Thus, when the word man calls up the ideas of an indefinite number of individuals, not only of all those to whom I have individually given the name, but of all those to whom I have in imagination given it, or imagine it will ever be given, and forms all those ideas into one, it is evidently a very complex idea, and therefore indistinct.’ (*Ibid.*)

Mr. Mill having gone through an exposition of abstraction, memory, belief, ratiocination, evidence, and some of the more complicated cases of naming, devotes the latter half of the second volume of his *Analysis* to the phenomena in which the sensations and ideas are to be considered as not merely existing, but also as exciting to action. He treats of pleasurable and painful sensations, and of the causes of the pleasurable and painful sensations; then of ideas of the pleasurable and painful sensations, and of the causes of them. He treats of wealth, power, and dignity, and their contraries, of our fellow-creatures, and of the objects called sublime and beautiful, and their contraries, contemplated as causes of our pleasures and pains. Chapter 22 is devoted to the subject of motives; and Chapter 24 to that of the will. Chapter 25 (the last) to intention. Mr. Mill’s exposition of all these phenomena is mainly grounded on the law of association, by which he means simply the fact that the order of occurrence amongst our ideas is the order of occurrence amongst our former sensations, of which those ideas are the copies.

Mr. Mill’s last work was the ‘Fragment on Mackintosh,’ published anonymously in 1835. This is a very severe criticism upon the ‘Dissertation on the History of Ethical Philosophy,’ contributed by Sir James Mackintosh to the ‘Encyclopædia Britannica.’ This work contains some very valuable disquisitions on morals, legislation, and jurisprudence, with some very clear and just remarks on the distinctions between these subjects, which are often confounded. Mr. Mill wrote several of the principal articles in the early numbers of the ‘Westminster Review.’ Among the contributions which are considered his best, are the article on the Formation of Opinions, in No. XI., and the article on the Ballot, in No. XXV.

Mr. Mill died at Kensington, June 23, 1836.

MILLAR (Professor), JOHN, son of the Rev. James Millar, minister of the parish of Shotts, was born in that parish on the 22nd June, 1735. Two years after, his father was translated to the parish of Hamilton in the same presbytery, and young Millar was about the same time placed under the charge of his uncle, Mr. John Millar of Milhaugh, in the neighbouring parish of Blantyre. At the age of seven he was put by his uncle to the school of Hamilton, and thence sent to Glasgow college, where he distinguished himself by his diligence and attention. He was at first designed for the church; but while at college he adopted the resolution of studying for the bar. On leaving college he became preceptor to the eldest son of Lord Kames, in whose family he spent two years, during which he formed an intimacy with David Hume and other eminent individuals. On the 9th of February, 1760, Millar passed advocate (*Faculty Record*); but having undertaken at this early period of his life the cares and burden of a family, he was soon obliged to abandon his prospects at the bar, and an opportune vacancy having occurred in the chair of civil law in Glasgow college, he applied for and obtained that situation the following year (1761). He now devoted himself entirely to the duties of his new sphere, and by his conduct in it

raised the class from a very low and languid condition to be the most popular of the law chairs in the kingdom. ‘His manner was familiar and animated, approaching more nearly to gaiety than enthusiasm; and the facts which he had to state, or the elementary positions he had to lay down, were given in the simple, clear, and unembarrassed diction in which a well-bred man would tell a story or deliver an opinion in society. All objections that occurred were stated in a forcible, clear, and lively manner; and the answers, which were often thrown into a kind of dramatic form, were delivered with all the simplicity, vivacity, and easy phraseology of good conversation. His illustrations were always familiar, and often amusing; and while nothing could be more forcible or conclusive than the reasonings which he employed, the tone and style in which they were delivered gave them an easy and attractive air, and imparted to a profound and learned discussion the charms of an animated and interesting conversation.’ (*Edinburgh Review*, vol. iii. *) But this was not all. It was also in no small degree owing to his practice of *examining* his pupils, and prescribing essays on subjects previously discussed in his lectures, that Millar acquired the high reputation as a professor of law which still attaches to his name. Every day before he began his address from the chair he endeavoured to ascertain by examination of his pupils whether they had followed his reasoning on the preceding day; and when the lecture was over he remained some time in the class-room to converse with such as were desirous of farther information. By engaging with them in an easy dialogue he removed obscurities and corrected misapprehensions; and the students were accustomed to acknowledge that it was at these meetings they derived the full benefit of the lectures. (*Jardine’s Outlines of a Philosophical Education*, p. 463.) Mr. Millar had also the good fortune, as we may call it, of long having scarce any rival chair to contend with; for from the time of Mr. Erskine’s resignation in 1765 onwards to the end of the year 1786, when Dr. David Hume was appointed, the chair of Scots law at Edinburgh was filled by Professor Wallace, who had too many employments to allow of his attention being devoted to any. Such accordingly was the success which attended Mr. Millar’s prelections, that his pupils rapidly increased in number, and the professor of civil law in the Edinburgh college, after seeing his students proportionally diminished, was obliged to abandon the practice, which had till then prevailed in his class, of lecturing in Latin, with the hope of retaining the remainder.

Although most of his lectures were attended with interest, yet remarking a more than ordinary degree of attention manifested to such of them as referred to the progress of society and government, Mr. Millar was induced from this circumstance to publish a short treatise on the subject. This he did in 1771, and the work was favourably received. Some years afterwards he began to turn his attention in a particular manner to the nature and origin of the English government; and in 1787 he published his ‘Historical View of the English Government, from the settlement of the Saxons in Britain to the accession of the House of Stuart.’ This work is described as ‘remarkable for the sagacity of its conjectures, the ingenuity of its explanations, the boldness of its discussions, and the total freedom from prejudice; but it is deficient in accuracy and research, and will not bring conviction to a mind that has received its first impressions from the plausible but delusive representations of Hume.’ (*Edinburgh Review*, xxx., 166-7.)

Mr. Millar was in stature about the middle size; his person was athletic, and his countenance very animated and expressive. He continued in good health till about the end of the year 1799, when he was seized with an inflammatory complaint, from which however he in a certain degree recovered; but having about a year and a half after exposed himself to cold, he was seized with a pleurisy, of which he died 30th May, 1801.

MILLE’NNIUM, a Latin word meaning a period of a thousand years, is applied by ecclesiastical writers to the period during which it is predicted in Scripture that the Church will be in a state of extraordinary prosperity, and which is to be preceded by the overthrow of her enemies, accompanied at its commencement by the first resurrection, or the resurrection of the saints, and followed by the destruction of Gog and Magog, and the general judgment. (*Rev.* xx.)

* The elaborate article of which the above quotation is a part has for its reputed author Francis Jeffrey, who is supposed to have been a pupil of Professor Millar’s.

Respecting the state of the church during the Millennium two opinions are held, both of which can be traced up nearly to the earliest ages of Christianity. The one is that Christ will reign in person upon the earth at Jerusalem, that the saints will reign with him and enjoy corporeal pleasures, and that the Jews will be restored to Palestine and exalted to the first rank among the nations of the world. This doctrine was held by Irenæus and others of the earlier fathers, not merely as their own opinion, but as the faith of the church received from the Apostles. These tenets were also held by Lactantius, who expected the Millennium to commence very soon after the time at which he lived. On the other hand it was held by Jerome and other fathers, who warmly opposed the doctrines just mentioned, that the passages of scripture on which they are founded must be taken in an allegorical sense, and that the Millennium will only be distinguished by the universal diffusion of pure Christianity in the world, and a consequent decrease of physical and moral evil. This opinion was adopted as the belief of the orthodox church, and has been almost universally received in modern times. The followers of the late Rev. Edward Irving and some other small sects, as well as many individuals among other bodies of Christians, still hold the doctrine of the personal reign of Christ on earth. Such persons are commonly called Millenarians, the name applied in the early ages of the church, together with the corresponding Greek word Chiliasts, to those who held these opinions. (Lardner's *Credibility*; Middleton's *Free Enquiry*, page 46.)

MILLEPORIDÆ. In the Linnæan 'Systema Naturæ' the genus *Millepora* included fourteen species of solid corals perforated with conical non-lamelliferous pores. Several of these have been taken as types of new genera or subgenera, and, according to the general practice of modern zoology, the Linnæan genus is transformed into a great family. Lamarck (*Anim. sans Vertèbres*, 11) places many of the Millepores in his fourth section of Polyparia, the foraminated corals, with *Catenipora* and *Tubipora*, which belong to other groups. The Milleporidæ form a distinct order in the Foraminated Polyparia of Lamouroux (*Expos. Méthod.*), and include no less than eighteen genera, viz. :—

Ovulites, *Retepora*, *Lunulites*, *Orbulites*, *Ocellaria*, *Melobesia*, *Eudea*, *Alveolites*, *Theonea*, *Chrysaora*, *Millepora*, *Terebellaria*, *Spiropora*, *Idmonea*. (Distichopora, Hornera, Krusensterna, and Tilesia are included among Milleporidæ in the table, but not in the body of the work.) The genera in Italics are fossil.

Lamouroux defines the Milleporidæ thus:—*Polyparia* stony, polymorphous, solid, internally compact; *cells* very small or poriform, scattered or in series, never lamelliferous, though the parietes are sometimes lightly striated.

Blainville collects the Milleporidæ into groups according to the form of the cells in the coral, and defines the family by characters drawn both from the animal and the stony support.

Animals in general very slender, and provided with a single circle of slender tentacula; *cells* sometimes of considerable size, but always without lamellæ or striæ within or without the tubes; *polyparium* fixed, varying in shape. Retrenching from the group the palmated kinds (to form the genus *Palmipora* among the *Madrephyllicæ*), there remain, according to Blainville, 23 genera, which are thus arranged :—

1. *Cells polygonal, often rather large.*—*Favosites* (*Eunomia*), *Alveolites*, *Apsendesia*, *Theonea*, *Pelagia*, *Terebellaria*, *Polytrema*, *Frondipora*, *Lichenopora*.

2. *Cells round, very fine, poriform, immersed.*—*Orbiculites*, *Marginopora*, *Stromatopora*, *Tilesia*, *Spinopora*, *Chrysaora*, *Ceripora*, *Distichopora*, *Heteropora*.

3. *Cells round, more or less tubular.*—*Pustulopora*, *Hornera*, *Idmonea*, *Cricopora*.

The following are the principal characters of these genera :—

§ 1. Cells polygonal.

Favosites.—*Animals* unknown; *cells* prismatic, contiguous, vertical or diverging, the parietes pierced with pores, the cavity divided by transverse septa; *polyparium* branched or massive, sometimes basaltiform.

A genus of Lamarck; Goldfuss added to the knowledge of its structure, but changed its name to *Calamopora*. Blainville thinks *Eunomia* of Lamouroux may be included in it, but the descriptions are unlike. Ehrenberg places it near *Astræa*, in the family of *Madrephyllicæ*, and we think with reason.

The *Favosites* are only known in a fossil state, and, we believe, only in strata of the 'Transition' and carboniferous eras, in the former of which they are specially abundant, in the Eifel, Siluria, at Dudley, &c.

Example, *Favosites Gothlandica*. (Goldfuss, t. 26, f. 3.)

Favosites Gothlandica.

a, b, two specimens; c, nuclei of the tubes; d, tubes magnified; e, portion of a vertical section.

Eunomia.—*Animals* unknown; *cells* tubular, long, parallel, internally sulcated longitudinally, and transversely annulated; the parietes thick and solid. (Lamouroux, *Expos. Méthod.*)

The only species, *Eunomia radiata*, is fossil in the oolitic series of Caen.

Alveolites.—*Animals* unknown; *cells* short, tubular, prismatic, alveoliform, the parietes thin; *polyparium* formed into reticulated layers, enveloping each other.

A genus of Lamarck, subsequently, but without sufficient reason, reunited by Goldfuss to *Favosites*, under the name of *Calamopora*.

Two living species and a few fossils, chiefly from the tertiary series of Dax. Blainville includes in the genus (not correctly) many of the *Calamopora* of Goldfuss which are to be ranked as *Favosites*.

Frondipora.—*Animals* unknown; *cells* unequal, subpolygonal, accumulated irregularly, prominent only on the external surface of a finely branched *polyparium*, which is fixed, arborescent, variously reticulated, and longitudinally striated on the non-celluliferous face.

One of the species is ranked as a *Retepora* by Lamarck.

Lamouroux (following Tilesius) calls it *Krusensterna*. The species are recent in the seas of Kamtchatka and the Mediterranean.

Example, *Frondipora reticulata*. (Blainv., pl. 69, f. 1.)

Lichenopora.—*Animals* unknown; *cells* rather large, poriform or subtubular, subpolygonal, accumulated and scattered on the interior surface of a fixed orbicular, cupuliform polyparium, which is quite smooth externally.

A genus of DeFrance, including one recent and three fossil species from the cretaceous and tertiary strata.

Example, *Lichenopora turbinata*. (Blainv., pl. 68, f. 4.)

Theonea.—*Animals* unknown; *cells* rather large and deep, subpolygonal, accumulated irregularly, prominent on the tumid or angulated face of the polyparium, which is fixed, irregularly lobed, and more or less lacunose between the accumulations of pores.

Example, *Theonea clathrata* (Lamouroux, pl. 80, f. 17), from the oolite of Caen.

Apsendesia.—*Animals* unknown; *cells* subpolygonal, small, poriform, irregularly disposed, occupying the upper and external edge of sinuous ridges, smooth on one side, plaited on the other; *polyparium* globular or hemispherical, diverging from the base to the circumference.

A genus of Lamouroux, from the oolite of Caen.

Example, *A. dianthus*. (Blainv., pl. 59, f. 2.)

Terebellaria.—*Animals* unknown; *cells* small, oval, sub-trigonal, quincuncially arranged on the surface of the *polyparium*, which is composed of short conical apparently twisted branches.

This beautiful coral, thus characterised, is found in the oolite of Caen, and, it is believed, also abundantly near Bath. Perhaps only one species is known, which Lamouroux divides into two.

Example, *Terebellaria ramosissima*. (Lamour., pl. 82, f. 1, a.)

Terebellaria ramosissima.

Pelagia.—*Animals* unknown; *cells* subpolygonal, close, irregular, occupying the convex edge of numerous vertical ridges, disposed in a radiating form, and either simple or dichotomous, on the upper surface of the coral; *polyparium* free, fungiform, excavated and lamelliferous above, convex, pedunculated, and circularly wrinkled below.

Example, *Pelagia clypeata*. (Lamour., pl. 79, f. 5, 6, 7.) From the oolite of Caen.

Polytrema.—*Animals* unknown; *cells* poriform, polygonal, irregular, unequal, numerous, occupying the knotty branches of a small fixed *polyparium*.

A genus of Risso.

Example, *Polytrema miniaëum*. (Blainv., pl. 69, f. 4.)

§ 2. Cells rounded, poriform.

Orbitolites.—*Animals* unknown; *polyparium* a regular, orbicular, discoid, cellular, cretaceous mass; *cells* in two layers, sometimes apparent externally, and especially at the margin, which is thickened.

A genus of Lamarck, apparently founded upon an *internal coral*. One recent European species, and several fossils from the chalk and tertiaries of Europe, are mentioned.

Example, *Orbitolites complanata*. (Blainv., pl. 72, fig. 2.)

Marginopora.—*Animals* unknown; *cells* poriform, excessively small, round, close, situated in the narrow tortuous folds of the circumference of the *polyparium*, which is free, irregular, discoid, thickened at the margin, and concentrically striated on both surfaces.

(Probably an internal coralline plate.)

Example, *Marginopora vertebralis*. (Blainv., pl. 69, f. 6.)

Stromatopora.—*Animals* unknown; *polyparium* hemispherical or subglobose, formed of alternately solid and porous adherent superposed layers.

The character is from Goldfuss, the author of the genus. The cells are very small, the external surface concentrically wrinkled. The species are fossil in the 'Transition' lime-

stone, &c. of the Eifel, Siluria, Dudley, &c. Mr. Lonsdale has described a new species similar to a *Nummulite* in figure.

Example, *Stromatopora concentrica*. (Goldfuss, 'Petri-facta Europæ,' tab. 8.)

Stromatopora concentrica.

a, surface reduced; b, vertical section reduced; c, portion highly magnified.

Ceripora.—*Animals* unknown; *cells* poriform, round, close, irregularly distributed in concentric layers; *polyparium* polymorphous, often globular or lamellar.

This genus was established by Goldfuss, but is curtailed by a stricter definition, by Blainville, to suit fossils which appear in the chalk of Maestricht and the 'Transition' rocks of Bamberg.

Example, *Ceripora micropora*. (Goldfuss, t. 10, f. 4.)

Chrysaora.—*Animals* unknown; *cells* periform, very fine, with a round opening, accumulated on the intervals of ridges, which anastomose on the surface of the fixed irregularly ramose *polyparium*.

A genus of Lamouroux, to which Blainville refers many of the *Ceripora* of Goldfuss, which belong to the oolitic formations.

Example, *Chrysaora spinosa*. (Lamour., pl. 81, f. 6.)

Tilesia.—*Animals* unknown; the *polyparium* formed of tortuous, verrucose, cylindrical branches; *cells* small, accumulated in irregular patches which project above the general surface, and are separated by smooth intervals.

Example, *Tilesia distorta*. (Lamour., pl. 74, f. 5, 6.) From the oolite of Caen.

Spinopora.—*Animals* unknown; *polyparium* adherent by a concave concentrically striated face below; above reticulated, tuberculated, and bearing between the tubercles poriform cells.

Fossil from the chalk. Three species.

Example, *Spinopora mitra*. (Blainv., pl. 70, f. 3.)

Distichopora.—*Animals* unknown; *cells* of two kinds, some stelliform, scattered, superficial, shallow; the others poriform, deep, unequal, forming three lateral rows on each side of the branches of an arborescent *polyparium*; these branches are compressed, obtuse, subflexuous, and tubulose within.

This Lamarckian genus contains the *Millepora violacea* of Linnæus. (Blainv., pl. 55, f. 2.)

Heteropora.—*Animals* unknown; *cells* round, poriform, completely immersed, of two sorts; some, larger than the others, are regularly dispersed on the whole surface of the *polyparium*, which is fixed, lobed, or branched, and formed of superposed laminæ.

A genus of Blainville, formed to include certain *Ceriopora* of Goldfuss which have two sorts of pores.

Example, *Heteropora cryptopora*. (Goldfuss, t. 10, f. 3.)

Heteropora cryptopora.
a, b, two specimens; c, pores magnified.

Fossil from the chalk of Maastricht.

Mr. Lonsdale mentions one from the Silurian Rocks. (Murchison's *Silurian System*, p. 880.)

§ 3. Cells round, and more or less tubular and prominent.

Pustulopora.—*Animals* unknown; *cells* rather prominent, pustulose or mammellated, distant, with round openings; *polyparium* formed of superposed laminæ, cylindrical, digitiform, or a little branched, fixed.

The few fossils which have these characters are separated from the *Ceriopora* of Goldfuss by Blainville. They are from the chalk and oolite.

Example, *Pustulopora madreporacea*. (Goldfuss, pl. 10, f. 12.)

Hornera.—*Animals* unknown; *cells* with a circular opening, prominent, detached, dispersed almost quincuncially on the inner face of the branches of a fragile ramulose *polyparium*, which is fistulose and furrowed on the non-polypiferous face.

A genus of Lamouroux, formed from *Retepora* of Lamarck. It includes several living species, from the seas of Europe and Australasia, and more fossils, chiefly from the tertiary strata, but Mr. Lonsdale notices one from the Dudley limestone.

Example, *Hornera frondiculata*. (Lamour., t. 74, f. 7, 8, 9.)

Hornera frondiculata.

a, natural size; b, c, fragments of the upper and lower sides, magnified.

Idmonea.—*Animals* unknown; *cells* prominent, sub-conical, distinct, with a circular opening, arranged in half rings or short cross-lines, on two-thirds of the circumference of the branches of the *polyparium*, which is not porous, but slightly channelled on the non-celluliferous face; the branches are divergent and triquetral.

One living species belongs to this genus of Lamouroux, and several fossils from the oolite of Caen, and chalk and tertiaries of Maastricht and Paris. Goldfuss has included two of them among *Retepora*.

Example, *Idmonea triquetra*. (Lamour., pl. 79.) From the oolite of Caen.

Cricopora.—*Animals* unknown; *cells* tubular, rather prominent, with a circular opening, arranged in rings transversely or obliquely on the surface of a fragile *polyparium*, which branches into cylindrical parts obtuse at the extremity.

This genus was named *Spiropora* by Lamouroux, but it is only rarely that the cells take anything approaching to

a spiral arrangement. The coral is *alveolar* through its mass. Some of the most characteristic species are fossils from Caen. *C. Faujasii* is from the chalk of Maastricht, and Blainville joins to the group two recent species, *Seriatopora annulata* and *S. nuda* (Lamarck). Ehrenberg calls the group *Myriazoon*, and Wiegmann *Truncularia*.

MILLER, SIR THOMAS, Baronet, second son of Mr. William Miller, writer to the signet, was admitted advocate at the Scottish bar in February, 1742, in the twenty-fifth year of his age. In 1748 he was constituted steward (or sheriff) of Kirkeudbright, and the same year elected joint principal clerk of the city of Glasgow. These offices he resigned in 1755, being then appointed solicitor to the excise in Scotland. In March, 1759, he was made king's solicitor-general: in April of next year, he was advanced to be lord advocate, soon after which he was returned to parliament. In November, 1762, he was chosen rector of Glasgow college. He continued in the post of lord advocate till April, 1766, when he was raised to the bench of the court of session, and succeeded Sir Gilbert Elliot, lord justice clerk, deceased; on which occasion he took his seat, by desire of the court, on the right hand of the lord president; and thence, on Dundas's death, he was, in January, 1788, elevated to the presidency of the court of Session, being the first lord justice clerk so promoted. The following month he was created a baronet. He died 27th September, 1789, leaving the present Sir William Miller, a judge in the court of session by the titular designation of Lord Glenlee, and other children.

It is to this distinguished person that the poet Burns alludes in these lines of his 'Vision':—

'Through many a wild romantic grove,
Near many a hermit-fenced cove,
Fit haunts for friendship or for love,
In musing mood,
An aged judge I saw him rove,
Dispensing good.'

MILLER, JOHN MARTIN, born at Ulm (where his father was preacher in the cathedral and professor of Oriental languages), December 2, 1750, was a novelist, whose productions made a great sensation in Germany in the last century. At Göttingen, where he went to study theology, in 1770, he became acquainted with Voss, Holty, Bürger, the two Stollbergs, and other eminent literary characters of the time, and afterwards with Klopstock, whom he accompanied on his return to Hamburg. After taking orders, he was appointed preacher at the cathedral of his native town in 1783, and in 1797 professor of theology at the Gymnasium. In 1810 the king of Wirtemberg bestowed the deanery of Ulm on him; but he did not live to enjoy it many years, for he died on the 21st June, 1814.

Although now almost forgotten, his romance of 'Siegwart' (first published in 2 vols., 1776, shortly afterwards greatly enlarged, and in many parts re-written) had astonishing success. It called forth a host of imitators, and had also the distinction of being parodied. It was translated into French, Polish, Dutch, Danish, and Italian. Like his 'Siegwart,' his 'Karl von Burgheim' and other novels have little action or interest of story, but are distinguished by pure morality and an amiable though exaggerated sensibility. This excess of sensibility and sentiment, which however was merely caricatured by his professed imitators, qualified him well for an elegiac and lyric poet; and his productions of that class are distinguished by the tenderness and religious feeling which they breathe. His sermons are likewise compositions of no ordinary merit, attractive in style, eloquent, and impressive.

In his personal character he is said to have been rather cold and reserved, and therefore disappointed many who expected to find in the author of 'Siegwart' an impassioned enthusiast. His romances may be forgotten, but his poems never can.

MILLES, JEREMIAH, dean of Exeter, was the son of Jeremiah Milles, and nephew to Dr. Thomas Milles, bishop of Waterford and Lismore. Bishop Milles left his fortune to his nephew Jeremiah, who was born in 1714, and educated at Eton. He afterwards went to Corpus Christi College, Oxford, where he took the degree of M.A. in 1735, and that of D.D. in 1747. His uncle collated him to a prebend in the cathedral of Waterford, and presented him to a living near that city, which he held but a short time, choosing to reside in England. Upon his return he married Edith, the daughter of archbishop Potter, through whose means he obtained the united rectories of St. Edmund

the King and St. Nicholas Acon, in Lombard Street, with that of Mersham, in Surrey, and the sinecure rectory of West Terring, in Sussex. In 1762 Dr. Milles was nominated to the deanery of Exeter, on the advancement of Dr. Charles Lyttelton to the see of Carlisle, whom he also succeeded as president of the Society of Antiquaries in 1769. In the 'Archæologia' are several communications by him: particularly one entitled 'Observations on the Wardrobe Account of the Year 1483, wherein are contained the Deliveries made for the Coronation of King Richard the Third, and some other Particulars relating to that Monarch;' and another (*Archæol.*, vol. iv., p. 331-346), in which he joined the abbé Barthélemy in denying the genuineness of the Apamæan medal. Mr. Gough informs us that, while dean of Exeter, he formed a large collection of materials for the 'History of Devonshire.' His most unsuccessful literary attempt was to vindicate the authenticity of Rowley's Poems, in an edition which he printed, in 4to., in 1782. The dean died February 13, 1784.

(Nichols's *Literary Anecdotes*, vol. iv., pp. 471, 472; Chalmers's *Biogr. Dict.*, vol. xxii., pp. 168, 169.)

MILLET, a plant which botanists class among the grasses, though, in some species and in favourable situations, it attains the height of 18 or 20 feet. (Burckhardt's *Travels in Nubia*, p. 280.) The stalk of all the species of millet resembles a jointed reed, having at every joint a long broad leaf, which embraces the stalk with its base. The plants are all annuals, and grow quickly, yielding an abundance of small grains which are set round a compact spike at the top of the stalk. The stalk itself is filled with a saccharine juice.

Millet thrives best in a light sandy soil, and if sufficient space is allowed between the plants to weed and hoe them during their early growth, they will afterwards overtop and smother all weeds, and yield an abundant return with little labour and without much manure. The seeds however require a climate warmer and drier than that of England to ripen properly. Millet is cultivated largely in the southern parts of Europe—in Spain, Italy, the south of France, Switzerland, and Southern Germany; but it is grown most extensively in the East Indies, China, Arabia, Syria, Egypt, and Nubia. It has also been introduced into the West Indies, where it is called *Guinea corn*, and is used as food for the negroes.

In the East millet is used as food for men; but in Europe, though it is sometimes made into loaves and cakes, and frequently into puddings, it is mostly used for feeding poultry and domestic animals. The leaves and panicles are given, both green and dried, as fodder to cattle.

Millet has been described by botanists under the generic terms *Holcus* and *Sorghum*. The most general species, the common Indian millet (*Holcus Sorghum*, Linn.), known in Nubia by the name of *Durra*, is described under *Sorghum vulgare*. We briefly notice the most important of the other species:—

Black millet (*Holcus niger*, Arduino) is one of the largest species. Caffre millet (*Holcus Cafer*, Arduino) is a native of the Cape of Good Hope. Yellow-seeded millet (*Holcus saccharatus*, Linn.) is a native of the East Indies. Two-coloured millet (*Holcus bicolor*, Linn.) is said to be a native of Persia. Drooping millet (*Sorghum cernuum*) is cultivated in Arabia, Syria, and various parts of the Levant.

MILLIN, AUDIN LOUIS, born in 1758, was an eminent French antiquary, who succeeded Barthélemy as keeper of the antiquities and medals in the Royal Library at Paris. His 'Dictionnaire des Beaux Arts,' 'Dictionnaire de la Fable,' 'Monumens Antiques,' and 'Galerie Mythologique,' are all useful contributions towards archæology and the fine arts. Besides these works, his 'Magasin Encyclopédique,' which he carried on for twenty years without seeking any profit from it, was a highly valuable literary journal, and may now be regarded as a repository containing much important information. To the above may be added his 'Voyage dans les Départemens du Midi de la France,' 'Voyage dans la Savoie,' and 'Voyage dans le Milanais.' These works possess a permanent interest on account of the historical and antiquarian matter which they contain. He died August 14th, 1818.

MILLION. [NUMERATION.]

MILLSTONE-GRIT is the title of a remarkable group of strata which belong to the carboniferous system and separate the coal formation from the mountain limestone. It may be regarded as one of the many instances of 'transi-

P. C., No. 940.

tion' on a large scale, which reveal to the geologist local changes of level and position of the ancient lands, whereby new currents were occasioned in the sea, and new depositions produced in its bed. Instead of the deposits of mountain limestone generated by processes almost purely marine, we have in the millstone-grit group evidence of streams from the interior of elevated lands and periodical currents which spread pebbles, sand, and clay, with land-plants, over surfaces where, previously, corals and shells were accumulated in the quiet sea. The character of this group varies according to a certain law of development, in passing from the south to the north of England. It is of little importance in the south-west of England, South Wales, or any of the midland coal-fields, but in Derbyshire it acquires great thickness, and appears in some of the most striking scenes of that romantic county. Here it is a series of thick arenaceous rocks, alternating with shales and flagstones below the coal and above the limestone. Perhaps no more remarkable feature in English geology can be noticed than the bold crags of millstone-grit which are crossed as the traveller proceeds from the coal of Sheffield to the limestone of Castleton.

Farther to the north, between the deep limestone dales of Yorkshire, the millstone-grit rocks appear on the summit of Ingleborough, Penyghent, and Wharfedale, mixed with shales, limestones, ironstones, and beds of coal. At least three distinct bands of coarse pebbly millstone-grit here occur, though not in one hill, and a similar character belongs to the series in Durham and Northumberland. Through all the extreme north of England indeed the millstone-grit group passes by its coal, ironstone, &c. to the coal formation above, and by its limestones and peculiar shales to the mountain limestone below, by so easy a gradation that the whole appears one vast series of associated deposits.

The rock from which the group is named, the millstone-grit, is a very coarse-grained quartzose sandstone, with layers of pebbles, often defining the upper or under surfaces of beds, and sometimes (as near Keighley) containing remarkable masses of laminated mica, which is not common in the substance of the stone. The most coarse and quartzose parts of the stone have a vague resemblance to unmicaceous granites (as that of Ravenglass), and this is strengthened by the occasional abundance of felspar, in large masses crystallized within, but fragmented or worn to a pebbly aspect externally. This discloses probably the true history of the rock. It is a re-aggregated mass of the disintegrated materials of granite; and as almost every sandstone of the coal districts is liable to assume locally the coarseness of grain of the millstone-grit, and all appear to contain felspar grains and fragments (often decomposed to porcelain clay), the importance of a study of the millstone-grit becomes evident. The organic remains are a mixture of those belonging to the coal formation (plants) and those of the subjacent limestone (coniferifera, mollusca).

MILNER, JOSEPH, was born in the neighbourhood of Leeds, on the 2nd of January, 1744. He was sent to the grammar-school at Leeds, where, by his industry and talents, among which a memory of most extraordinary power was conspicuous, he gained the warm regard of his instructor, the Rev. Mr. Moore, who resolved to have him sent to college. This plan was nearly frustrated by the death of Milner's father in very narrow circumstances; but by the assistance of some gentlemen in Leeds, whose children Milner had lately engaged in teaching, and by the offer of the office of chapel-clerk at Catherine Hall, Cambridge, he was enabled to enter that hall at the age of eighteen. In the year 1766 he took his degree of B.A., and gained the chancellor's second gold medal for classical knowledge. He now became assistant in the school, and afterwards the curate of the Rev. Mr. Atkinson, of Thorp Arch, near Tadcaster. Here he proceeded in the composition of an epic poem, entitled 'Davideis,' which he had commenced at Cambridge, and which he afterwards finished at Hull. It was submitted to Dr. (afterwards bishop) Hurd, who highly complimented the author on the talent it displayed, but advised him to defer its publication. Not long after he had obtained deacon's orders, Milner was elected head-master of the grammar-school, and afternoon-lecturer of the principal church of Hull. The school increased under his care. He not only introduced his younger brother to these literary pursuits in which he was afterwards distinguished [MILNER, ISAAC], but he also took his mother and two orphan children of his elder brother to live with him. About the year 1770 he embraced the sentiments of the

Vol. XV.—2 G

evangelical party in the church of England. This change in his religious views brought upon him neglect, and in some cases open opposition from many among the upper classes who had once been his admirers and friends; but his church was soon crowded with others, chiefly from the lower orders of the people, in whose sentiments and manners his preaching produced a striking change; and at length he not only recovered the esteem of his fellow-townsmen, but lived to see his own religious sentiments become so popular in the town that many of the pulpits of the churches were filled by his friends and pupils, and he himself was chosen vicar of Hull by the mayor and corporation. His election took place only a few weeks before his death, which happened on the 15th of November, 1797, in the 54th year of his age. For seventeen years before his death he had been vicar of North Ferriby, near Hull. A monument, executed by Bacon, was erected to his memory in the high church of Hull by several gentlemen who had been his pupils.

The excellencies of Mr. Milner's personal character were of the highest order. He was deeply pious, upright in all his conduct, singularly open and sincere, and kind, cheerful, and amusing in social life. In his political principles he was strongly attached to the established order of things in church and state.

The work by which he is best known is the 'History of the Church of Christ,' which was commenced by himself and completed by his brother, the dean of Carlisle, and which extends from the rise of Christianity to the Reformation. The first edition of this work appeared in 5 vols. 8vo., 1794 to 1812, and a second edition in 1810. It has been more than once reprinted. The plan of the history is thus stated in the author's Introduction: after stating that in all ages of the church there have existed 'men who have been *real*, not merely *nominal* Christians,' he proceeds:—'It is the history of these men which I propose to write. It is of no consequence with respect to my plan, nor of much importance, I believe, in its own nature, to what *external* church they belonged. I intend not to enter with any nicety into an account of their rites and ceremonies, or forms of church-government, much less into their *secular* history. Even *religious controversies* shall be omitted, except those which seem to bear a relation to the essence of Christ's religion, and of which the history of his real church requires some account. Let not the reader expect that the actions of great men (great in a secular view, I mean) will be exhibited to his notice. Nothing but what appears to me to belong to Christ's kingdom shall be admitted: genuine piety is the only thing which I intend to celebrate.' It is manifest that on this plan no *complete* church history can be written. Such a work ought assuredly to record the religious opinions and practices which have at any time prevailed among any of those who profess the Christian faith; leaving the reader to conclude, from these materials, which parties have been right and which wrong. But on Milner's plan we have avowedly the history of only one class of opinions, and the choice of this class is determined solely by their agreement with the sentiments of the author. Now, to say nothing of the temptation to do violence to facts, to which an author is exposed who is determined to trace the existence of certain principles in all ages of the church (a temptation from which it is but just to add that Milner has escaped), it is clear that, writing on this plan, two ecclesiastical historians of opposite creeds would produce works containing very different sets of facts, but each professing to be a 'History of the Church of Christ.' Though, for these reasons, Milner's work cannot be called a *complete* church history, its value as a *contribution* to church history is very great. It is written in that spirit of piety, and of deep interest in what the author believes to be true religion, which is not always found in our celebrated church historians; and for the very reasons which prevent its being complete, it contains many important facts which had previously been little attended to. It surpasses most other church histories in the use made of the writings of the Fathers, though the reverence which the author professes for those venerable men has led him to trust them too much.

The other works of Mr. Milner are,—1, 'Gibbon's account of Christianity considered; together with some Strictures on Hume's Dialogues concerning Natural Religion.' 2, 'Some Passages in the Life of William Howard.' 3, 'Essays on the Influence of the Holy Spirit.' 4, 'Tracts and Essays, Theological and Historical.' 5, 'Practical Sermons; with

an Account of his Life, by the Dean of Carlisle,' 2 vols. A complete collection of his works was edited by the dean of Carlisle, 8 vols., 1810.

MILNER, ISAAC, dean of Carlisle, and brother of the preceding, was born in 1751. At the age of six he began to accompany his brother to the grammar-school at Leeds; but at his father's death his studies were interrupted, and he was employed in learning the woollen manufactory at Leeds. When Joseph Milner was appointed head master of the grammar-school at Hull, he released his brother from his engagements at Leeds, and took him under his own tuition, employing him as his assistant in teaching the younger boys. In his life of his brother the dean expresses his sense of this act of kindness with an affectionate warmth which shows the attachment that existed between the brothers, and is equally creditable to the feelings of both. In 1770 Isaac Milner entered Queen's College, Cambridge, where he took his degree of B.A. in 1774, and was Senior Wrangler. In 1775 he was elected Fellow of Queen's College, and in 1783 Jacksonian Professor of Experimental Philosophy; in 1788 he took his degree of D.D., and was elected Master of Queen's College; and in 1798 he was appointed Lucasian Professor of Mathematics. In 1791 he was appointed Dean of Carlisle. He was twice Vice-Chancellor, in 1792 and 1809. At Cambridge he formed a close friendship with the late Mr. Wilberforce, by whom he was introduced to Mr. Pitt; and in company with those eminent men he made a tour on the Continent about the year 1787. He died at the house of Mr. Wilberforce, at Kensington Gore, on the 1st of April, 1820.

Dean Milner was possessed of very extensive and accurate learning, which he always had at his command. He had great talents for conversation, and a dignified simplicity of manner. His religious and political principles agreed pretty closely with his brother's. He wrote the following works, besides several scientific papers in the 'Philosophical Transactions,' and the continuation of his brother's 'Church History':—'Animadversions on Dr. Haweis's History of the Church of Christ;' 'Strictures on some of the Publications of the Rev. Herbert Marsh, intended as a Reply to some of his Objections against the Bible Society.' The following were published after his death:—'Sermons,' 2 vols.; 'Essay on Human Liberty.'

('Memoir of Dean Milner,' in the *Christian Observer* for May, 1820, vol. xix., p. 289.)

MILO', MELOS, one of the larger Cyclades in the Ægean sea, about 70 miles north of the coast of Crete, and 65 east of the coast of the Peloponnesus. It is 14 miles long from east to west, and its breadth is about eight miles. Its northern coast is indented by a deep bay, which forms a natural harbour, one of the best and safest in the Levant. The surface of the island is mountainous, and of volcanic formation; it has hot mineral springs, and mines of sulphur and alum. The soil is fertile, and produces abundance of fruit, wine, oil, and pasture for cattle. The population, which was above 20,000 in the time of Tournefort, about a century ago, has greatly decreased; it is now stated vaguely at 7000 by Balbi, and at only 1500 by Thiersch, but this last estimate appears too low.

Besides the chief town, called also Milo, which is in the east part of the island, near the port, there are several villages, called Pollone, San Dimitri, Castro, &c. The lower grounds near the sea are marshy, and are said to render the air unwholesome in summer.

Melos is said to have been colonised first by the Phœnicians, and afterwards by the Lacedæmonians. During the Peloponnesian war the Athenians sent an armament to reduce it under the command of Nicias, the son of Niceratus, but the attempt failed. Some years later in the war a new expedition from Athens landed on the island, and after a siege of several months took the town of Melos, when the Athenians put to death all the adult males, and carried away the women and children as slaves, after which a colony of Athenians was sent to occupy the place. (Thucyd., iii. 91; v. 84, &c.) At a later period Melos, like the other Greek islands, became subject to Rome, and afterwards to the Byzantine emperors, the Venetians, and the Turks. It now forms part of the new kingdom of Greece.

There are extensive remains of the ancient capital of the island, Melos, near the great harbour, consisting of part of an amphitheatre, cyclopean walls, a temple of Venus, and numerous subterranean galleries. A fine statue of Venus, found at Melos, is in the museum of the Louvre at Paris.

A number of vases and other antiquities have been discovered among the ruins.

Near the north-east extremity of Milo is the rocky island of Cimolos, called by the Italian sailors *Argentiera*; the channel between the two is very dangerous in stormy weather, and noted for shipwrecks. (Dapper, *Description des Isles de l'Archipel*; Porcacchi; Tournefort.

MILONOV, MICHAEL, a Russian poet of considerable talent, and who, but for his premature death, would probably have risen to greater literary eminence, was born in 1792, and received his education at the university of Moscow, where he distinguished himself by his application and abilities. His poems, which were first published in a collective form in 1819, consist chiefly of satires, epistles, and various lyrical pieces, and display elevation of mind, acute thinking, and tender feeling. Among them are some translations and imitations from Horace, Schiller, and others. He died October 17-29, 1821.

MILTIADES (Μιλτιάδης) was the younger son of Cimon (who was sprung from a noble Athenian family), and nephew of the elder Miltiades, who, during the life of Pisistratus, had founded a tyranny, or arbitrary government, in the Chersonese. The elder Miltiades had been succeeded by Stesagoras, the elder son of Cimon, on whose death the young Miltiades succeeded to his place. The first important affair in which Miltiades appears is at that juncture, during the Seythian expedition of Darius, B.C. 513, when the Greek commanders who guarded the raft over the Danube debated whether they should not cut off the Persian king's retreat by breaking up the passage. Miltiades advised the destruction of the bridge, and although his opinion was overruled, it is not too much to suppose that his reason for advocating it was exactly that on which it was afterwards rejected. So shrewd a politician could hardly have failed to observe, that to annihilate the Persian power was, as Histæus suggested, tantamount to giving all the tyrants of individual cities their dismissal.

Twenty years afterwards, Miltiades was called upon to act a more important part. Hipparchus, one of the sons of Pisistratus, had fallen by the hands of Harmodius and Aristogiton; and Hippias, the other son, who had been driven from Athens chiefly by the aid of the Spartans, had retired, as Greeks both then and subsequently often did under similar circumstances, to the Persian court. In Ionia, the burning of Sardis was followed by a war which lasted for six years, in which each party seemed to have learned a lesson: the Persians, that their enemy was not altogether despicable; and the Greeks, that without unity of plan there was no hope of success.

In B.C. 492, Mardonius led the first Persian armament, which was dispersed by a storm in doubling the peninsula of Athos. In B.C. 490, a second armament under Datis and Artaphernes was sent against Greece. This force crossed to Naxos, and thence to Delos and Eubœa. A few days sufficed to sweep through the island of Eubœa, and the whole armament made for the coast of Attica. Guided by Hippias, who knew the capabilities of every spot of ground in his country, the army landed at Marathon. [MARATHON.] The plain of Marathon extends inwards from the sea to the mountains, where it is contracted into a narrow glen by the spurs of two hills, but spreads out beyond the base of these spurs and between them and the sea. It is roughly in the form of a T, the top stroke representing that part which borders on the sea, and the leg of the letter corresponding to the glen, which is divided lengthwise by a mountain stream. Through this glen lay the road to Athens, and on the eastern side of the hill the Athenian army posted itself.

According to custom, the army was under the direction of ten generals, each of whom took the command for one day in turn. One of the ten was Miltiades, who had just been acquitted on a charge of tyranny, more perhaps owing to the politic way in which he had used his power in the Chersonesus, than to the real merits of his conduct. He had a powerful ally in the polemarch Callimachus, who, by virtue of his office, commanded the right wing, and had an equal vote with the ten generals. The votes of the generals being divided on the question of an engagement, Callimachus, by his vote, decided for fighting; and when the day of command came round to Miltiades, the battle took place. The Persian army was much more numerous than that of the Greeks, who are generally reckoned at 10,000. In the centre of the Persian host were stationed their best soldiers, a precaution necessary in order to give some sta-

bility to an army composed of forty or fifty different tribes, but injurious inasmuch as it exposed them to the very manœuvre which Miltiades practised, and with a view to which he apparently arranged his forces, so that the centre might be weak and the wings strong. The Persian centre broke that of the Greeks, and pursued them toward the hills, but in each wing the Athenians, who had charged at double-quick time, dispersed those who were opposed to them, wheeled round and routed the victorious Persians. This decided the battle. The vanquished perished in thousands, by the sword, in the marshes, and in attempting to embark on board their ships; and the Athenians and their allies the Plataeans were left completely masters of the field. Herodotus states 6400 as the number of the Persian dead, and 192 the number of the Athenians who fell. The tactics practised at this battle are worthy of remark, as being so completely opposed to the Dorian plan of preserving a close and impenetrable phalanx, and much more nearly allied to those of modern warfare. Perhaps no battle ever reflected more lustre on the successful commander than that of Marathon on Miltiades; though it should be observed, that he, whom all ages have regarded as the defender of liberty, began his career as an arbitrary ruler, and on only one occasion in his whole life was engaged on the side of freedom; but for the same man to be the liberator of his own country and a despot in another is no inconsistency, as the course of human events has often shown.

The battle of Marathon put an end to the expedition headed by Datis and Artaphernes, and the career of Miltiades closed soon after. He appears next at Paros, to which he laid siege with seventy Athenian ships. The Parians defended themselves bravely, and, if we may believe Herodotus, Miltiades had recourse to magic, in the practice of which he received a wound, which, with general ill success, compelled a retreat. On his return, while yet suffering from a gangrene in the wound, he was accused, tried, and condemned for deceiving the people. The punishment was commuted for a fine; but being unable to pay it, he died in prison.

The character of Miltiades is one on which, with the few materials which history has left, we should not judge too exactly. The outline which remains is one that, if filled up, would seem fittest to contain the very model of a successful statesman in an age when the prime minister of Athens was likewise the leader of her armies. Heeren has briefly noticed the transition which took place in the character of Athenian statesmen from the warrior like Themistocles and Miltiades to the warlike rhetorician like Pericles, and thence to the orator, who to his rhetorical skill united no military prowess. Miltiades with great generalship showed great power as a statesman, and some, but not much, as an orator. This is agreeable to his age. Whether he was a true patriot, governed by high principle, it is now impossible to determine. He achieved one great action, which for his country produced a most decisive result. The unfortunate close of his career may be considered by some as showing the ingratitude of democracies; but perhaps a judicious historian will draw no conclusion of the kind, especially with such imperfect materials before him as we possess for the life of this illustrious Athenian.

(See Herodotus, lib. v., vi.; Cornelius Nepos, whose biography of Miltiades is of no value; Plutarch; Thirlwall's *History of Greece*; and Clinton's *Fasti*; for the office of Strategus, Schömann and Meier's *Attische Process*; and for the topography of Marathon, Pausanias, Dodwell, and E. D. Clarke's *Travels*.)

MILTON. [KENT.]

MILTON, JOHN, son of John and Sarah Milton,* was born December 9, 1608, at his father's house in Breadstreet, London. He was of a good family, his father having been educated at Christ Church, Oxford, but was disinherited for turning Protestant. He was a man of great musical acquirements, and specimens of his composition are preserved in Burney's 'History of Music.'

Milton's education appears to have been sedulously conducted; first under a person of Puritan opinions named Young, who was master of Jesus College, Cambridge, during the Protectorate, and afterwards at St. Paul's School under Alexander Gill. From St. Paul's he proceeded to Christ's College, Cambridge, where, as the College Register informs us, he was admitted, February 12, 1624.

At the University he was distinguished for the peculiar

* The name is spelt Mylton in the baptismal register.

excellence of his Latin verses, and, according to his own expression, met with 'more than ordinary favour and respect' during the seven years of his stay there. It will be unnecessary here to go into the momentous question whether Milton was whipped at Cambridge. Dr. Johnson is 'ashamed to relate what he fears is true, that Milton was one of the last students in either university that suffered the public indignity of corporal correction,' and Warton, in an elaborate commentary on Milton's first elegy, draws from the words a meaning which would have startled the author: but there appears small reason to believe the fact.

After having declined both the church and the bar, he retired to his father's house at Horton in Buckinghamshire, where, during a residence of five years, he read over all the Greek and Latin classics, and, as it is supposed, wrote his 'Arcades,' 'Comus,' 'L'Allegro,' 'Il Penseroso,' and 'Lycidas.' Attempts have been made to fix the precise place where some of Milton's minor poems were written, by a reference to the descriptions of scenery contained in them. It appears to us that these attempts depend on a mistaken principle; that, namely, of assuming the poet's mind to be influenced in such matters by the scenery with which he is at the time familiar. Now that localities must affect a person who is writing descriptive poetry, no one will deny; but in purely imaginative poetry, like 'L'Allegro' or 'Il Penseroso,' we cannot attach any great weight to such considerations, particularly when the descriptions are so general, and when the describer is Milton.

In 1637, on the death of his mother, Milton travelled into Italy, during which journey he was introduced to Grotius, to Galileo, and to Tasso's patron, Manso. While in Italy news reached him of the progress of the troubles in England. Relinquishing his original intention of prolonging his journey to Sicily and Greece, he returned, after an absence of fifteen months, and devoted himself to the education of his nephews, John and Edward Phillips, and to the politics of the day. Much has been said on his system: Dr. Johnson has sneered at it; and more modern authorities have caught at it in order to support a convenient theory, each perhaps without reflecting much on the subject. The tendency of his scheme was not to supply the then existing deficiency of instruction in the knowledge of nature, or to substitute some other treatise on such matters for the works of Aristotle, but to exchange, as quietly as possible, and at the same time as decidedly, the merely formal routine of classical teaching for one in which the books that were read might arouse thought as well as exercise memory. His list comprises almost all the technical treatises extant in Latin and Greek, but excludes history and almost all the better known books of poetry, probably because he only intended it for children, and postponed such subjects for the instruction or amusement of riper years. His aims were not those of a mathematician or the philosopher of nature; the state, not science, was in his view, and his object was to make, not good members of a university, but well-informed citizens. To this tend his eulogy of manly exercises and his plans for a common table, which could have had little importance in the eyes of a student.

In 1641 Milton began his political career by writing a treatise 'Of Reformation,' which was followed in the same year by those on 'Prelatical Episcopacy,' 'The Reason of Church Government urged against Prelacy,' and some animadversions on a tract of Bishop Hall's, and in the next by 'An Apology for Smectymnuus.'

In 1643 he married his first wife, who was the daughter of a country gentleman of Oxfordshire. Not long afterwards his conjugal troubles began, by the refusal of his wife to return to him from a visit to her father. He accordingly repudiated her, and in 1644 and 1645 published four treatises in justification of his conduct. The former year is also remarkable as that in which he produced his 'Tractate on Education,' and that most able of all appeals, the 'Areopagitica, or a Speech for the Liberty of Unlicensed Printing,' a work which contains in the same space more passages of surpassing eloquence than any other which proceeded from his own or from any other pen.

About this time Milton was reconciled to his wife, whose family had been reduced to distress by their devotion to the royal cause.* His pen was silent until after the execution of Charles, when he produced a tract on 'The Tenure of Kings and Magistrates; proving that it is lawfull to call

to account a tyrant or wicked king.' &c. This was followed by 'Observations on the Articles of Peace, and Animadversions on the Scotch Presbytery at Belfast,' in the same year (1649). His next work, 'The History of England,' was interrupted by his appointment to the post of Latin secretary to the Council of State, which had determined that the Latin language should be used in all foreign negotiations, a custom which has not been dispensed with until lately as far as treaties are concerned. At present, treaties are written in French, in addition to the languages of the parties to it; and disputes on the text are settled by an appeal to the French version. The Council could not have chosen any man in England better qualified for the office by his sound scholarship and his ready command of the Latin language; but it is to be regretted that in his controversies with Salmasius he should have stooped to criticise style instead of weighing arguments. In his new capacity Milton was deputed to answer 'Eikon Basilike,' which he did in his 'Eikonoklastes;' and soon after to rebut Salmasius's vindication of monarchy, by his 'Defensio Populi Anglicani,' of which two books Hobbes declared himself unable to determine whose language was best or whose arguments worst.

After his appointment as Latin secretary he changed his abode to Westminster. Upon the death of his first wife he married a daughter of Captain Woodcock of Hackney, who died in childbed within a year of their marriage. In 1654, or perhaps before that time, he became totally blind, a misfortune which his enemies considered as a judgment from Heaven.*

The duties of his office, occasional pamphlets on politics, and his 'History of England,' which appeared in 1670, employed him till he began 'Paradise Lost.' At the Restoration he retired into obscurity; but he seems to have incurred no particular danger, although he was once in custody of the serjeant-at-arms. Some ascribe his safety to Sir W. Davenant.

Having obtained indemnity under an act passed in 1660, he married his third wife, Elizabeth Minshull; and in 1665, according to Elwood the Quaker (who acted in some measure as his secretary), he had completed 'Paradise Lost,' which was shown to Elwood in a finished state in that year, during a visit paid by Milton to some friends of Elwood's in Buckinghamshire. The poem was licensed and published in 1667. Five pounds were paid by Samuel Simmons, the bookseller, for the copy, with a promise of five pounds more when 1300 copies should have been sold, of the first, second, and third editions respectively. The 'Paradise Lost' first consisted of only ten books. The division into twelve was made in the second edition, published in 1674, three years before which time he had produced 'Paradise Regained' and 'Samson Agonistes.'

In 1673 he published a 'Summary of Logic;' in 1673 a treatise 'Of True Religion,' &c.; and in 1674 his Latin letters and exercises. His last work was a translation of the Polish declaration in favour of John III. He died on Sunday, November 8, 1674, and was buried in the chancel of St. Giles, Cripplegate.

For full information on Milton's life, his habits, appearance, &c., the reader is referred to the very copious Life by Todd, prefixed to his edition of Milton's Poetical Works.

Milton belonged to the Independents, a name in his time expressive both of religious and of political tenets. He seems to have been as bold in speech as in writing, and this boldness, so early as the date of his Italian journey, gave his friends some uneasiness for his safety. But Milton did not consider, as some have supposed, that in entering on controversy he was following the bent of his nature: he calls it expressly a 'manner of writing, wherein knowing myself inferior to myself, led by the genial power of nature to another task, I have the use, as I may account it, but of my left hand.' After the death of Charles he took a decided part against the Presbyterians, as is shown by his tract on the Tenure of Kings, and became the champion of republicanism against Salmasius. This was the period of his greatest celebrity. As Latin secretary he held an official residence for eight years, and divided the curiosity of foreigners with Cromwell himself. Yet, at the Restoration, he had no hardships to complain of, except the exorbitant fees charged by the serjeant-at-arms, and it is even said that he had the refusal of his original office.

* The passage in 'Paradise Lost,' where the scene is supposed to be described, is well known (b. x., v. 940).

* A curious account of his blindness is given in his own words, 'Latin Epistles,' No. xv.

It would be out of place here to do more than notice in a cursory manner Dr. Johnson's critique of Milton's poetry. To attempt by writing to impress the beauties of an imaginative work upon those acquainted with that work is a task more easy than useful; for those who do not appreciate poetic beauty without the guidance of another man's judgment will seldom form any opinions of their own worth possessing: and in like manner those who are not by their own taste directed to see the faultiness of a critique like that to which we have referred, will probably derive little benefit from being told that it has faults. But there is another class of readers to whom it may be well to direct a few observations; those, we mean, whose taste is accurate enough to enable them to trace faultiness as pervading the system, though they cannot discern its particular mistakes. In any criticism, on whatever subject, it is most important that the spirit in which the work subjected to criticism was written, should be kept in view by the critic. With this restriction and condition an imaginative work like 'Lycidas,' written in the style of a school of Greek poets, of which Theocritus is the model, would never be called 'easy, vulgar, and therefore disgusting;' and its rhymes and numbers would not have been stigmatised as uncertain and displeasing by any one who reflected that Milton had Italian models in view when he wrote 'Lycidas' in verses of unequal length.

Let no one try to render a poem, even epic or dramatic, into an historical form. Charles Lamb has attempted it; a man perhaps more likely to succeed than any of his age; and his prose Shakspeare would rather deter than provoke imitation. The absurdity of reducing a chapter of Hume's 'History of England' into a metrical shape, and then criticising it as a poem, is sufficiently manifest; but when we come to an imaginative work like 'Il Penseroso,' dissect it into elements, and make these elements purely narrative, persons are and have been deceived into supposing this dissection to be legitimate criticism.

'Paradise Lost,' perhaps the greatest continuous effort of human imagination, had originally the form of a drama, of which several plans remain. The epical form however at last asserted its superiority, although enough of the drama remains in the present poem to enable us to trace with some distinctness the shape which it probably assumed. In spite of all that has been said and written on 'Paradise Lost,' the truth of Dr. Johnson's observation must be to a considerable extent allowed, that it is 'one of the books which the reader admires and lays down, and forgets to take up again.'

Much of this inattention is no doubt owing to the character of this age. Learned poetry suits us not. We require either passionate and powerful description, like Byron's; imitations of antiquity so disguised that we are not all of us able to trace them, like Walter Scott's; or thoughtful poetry, either couched in sensuous imagery, like that of Shelley, or aspiring to be philosophical, like that of Wordsworth. But for allusions to classical authors, however beautiful, for an exhibition and exposition of the leading doctrines of Christianity, couched in language however sublime, and for a history of events so gigantic, we have no taste when conveyed in the form of a poem. In other words, 'Paradise Lost' is not and cannot be extensively popular; and even among its admirers we shall detect many who judge of it not as a poetical but as a theological production. Taken as a whole, a proper estimate cannot be formed of it by any one who has not learning enough to enable him at least to perceive the learning of the author; and the same may be said of the dramatic works of Milton, for the allusions to passages in the Greek tragedies which are contained in the first few pages of 'Samson Agonistes' are almost equal in number to the lines themselves.

Milton's poetry cannot be dismissed without a word or two on his versification. His matchless ear led him to choose blank verse—a measure till then almost unknown except in dramatic works—as the best metre for an epic poem. To the same quality is owing the harmony of his lyrical verses, in which, as in everything else, he seems to have been a century in advance of his own time. If we compare his liquid verses with the lilting jingle which characterises almost all the versifiers of the last century who attempted the octave stanza, the difference will be immediately discerned. It was not until Milton began to supersede the French school that English poets produced verses approaching his own in sweetness. Such are some

of Coleridge's and Shelley's, not to mention Scott, who borrowed his measures from other sources.

Of all authors, antient and modern, respecting whom conflicting judgments have been pronounced, no one has had more to contend with, both from the unwise conduct of his friends and the malice of his enemies, than Milton. Living at a time when party spirit ran high, and identifying himself with one of the extremes, his character has been assailed by many enemies, and of his defenders not a few have made up by violence what they wanted in discretion. It is part of our national habits to regard every man who can be so regarded, not according to his eminence in art or science, so much as according to his station as a political partisan. This is no theory, but a positive fact, which fact has become more generally true during the last half century from the accident of that literature by which the opinions of a great portion of the reading public is guided—the periodical literature—having assumed a tone decidedly political. Thus Milton is often viewed, not as a poet, not as a writer of all writers most eloquent, but as a partisan. And yet, until we divest ourselves of this deep-engrafted habit, we shall never read Milton's prose works as they ought to be read; we shall never see in them the commentaries on his own poetry which they supply; never trace those models of eloquence which they contain; never reflect that in Milton's polemics we find the perfection of a reviewer's style, with all the acumen and not half the heaviness of Bentley, and with qualities more adapted to controversy than any which have been exhibited from his time until the beginning of the present century; that in his historical fragment exists a mythological narrative written not less poetically than Niebuhr's 'Lays' and 'Legends' of Roman History, although Niebuhr was the first who followed, however unconsciously, this great example; and that in his 'Speech for the Liberty of Unlicensed Printing' the sentiments are noble, and are more nobly expressed than in any English composition before the days of Burke. It is as rhetorical models that we must view Milton's prose works; his logic may fail, his facts and arguments may be insufficient, but his eloquence remains unrivalled.

A curious change took place even during Milton's lifetime in regard to public taste. The Shaksperian drama, that wonderful combination of active and reflective poetry, gave place to a bad imitation of an unnatural model, the French heroic play. Italian measures, those which Surrey, Shakspeare, and Milton had all more or less practised, were supplanted by the ten-syllable rhyming couplet of Dryden, imitated also from the French. In fact the nation took their cue from the court in matters of taste, and the court was not less subservient to French influence in literature than in politics. Whenever a good history of the eighteenth century shall be written, the historian will do well to trace distinctly the way in which English literature has been gradually recovering from the taint which it contracted after Restoration, as affording a curious illustration of the manner in which opinions on taste and on politics go hand in hand. And no such history can be written without including a deliberate investigation of the influence which Milton has exercised, and the esteem in which he has been held, particularly among the nonconformists, a body of men whose power, because silently applied, has been often underrated or even overlooked.

The editions of Milton's poetical works are very numerous. His prose works have been much neglected, and we are not aware that a uniform edition including the tract on Christian Doctrine has yet appeared.

In the year 1823 a Latin manuscript, with the title 'De Doctrina Christiana, libri duo posthumi,' was discovered in the State-Paper Office, and, from internal and other evidence, was ascertained to be the work which Milton was known to have written on this subject, and which was supposed to be lost. It was edited by the present bishop of Winchester (Sumner), and a translation was also published. This work is characterised by the usual boldness and freedom of opinion which pervade all Milton's writings. As a theological work, it is perhaps almost unnecessary to remark that it would be considered of little value by any denomination of Christians.

(Todd's *Life of Milton*; *Milton's Works*.)

MILVUS. [FALCONIDÆ, vol. x., p. 187.]

MIME (from the Greek *mimos* (μῖμος), an imitator), a dramatic performance of irregular form among the Greeks, in which occurrences of real life were clothed in a poetical

dress. It usually consisted of a single scene, mostly comic, sometimes with such dialogue added as the excitement of the moment prompted. Mimes appear to have been common entertainments at feasts. Sometimes they were acted on the stage. Sophron of Syracuse (born about B.C. 420), who wrote in the vulgar dialect of the Doric Greek of Sicily, is considered the inventor of this species of composition. His mimes were in rhythmical prose, and were highly esteemed by Plato, who is said to have carried to Athens the taste for this species of composition. With the exception of a few fragments, and the names of some of his mimi, the works of Sophron are lost. The fragments of Sophron are collected in the 'Museum Criticum,' No. VII. We have specimens of a mime in the fifteenth idyll of Theocritus. Philestion of Nicæa, another writer of mimes, was contemporary with the latter years of Socrates. Suidas (*Φιλιστιων*) calls his mimes *biologic*, or 'pictures of life.'

Among the Romans, mimes seem to have been nothing but irregular harlequinades, probably the lineal ancestors of our 'Punch.' In the time of Augustus, Bathyllus and Pylades divided the taste of the Roman capital as actors of mimi. Among the mimographers of Rome we find Mattius, Laberius, and Publius the Syrian, the second of whom died B.C. 43, when the third was in the height of his popularity. Laberius acted as well as composed mimes. In the reigns of the earlier emperors we meet with other mimographers of celebrity, but none came up to the reputation of Laberius and Publius.

(Macrob., *Sat.*, ii. 74; Suetonius, *Cæs.*, c. 39; Ziegler, *De Mimis Romanorum*, Göttingen, 1789, quoted in 'Conversations Lexikon.')

MIMNERMUS OF COLOPHON, a Greek elegiac poet, contemporary with Solon. Müller, quoting a fragment of Minnermus's elegy 'Nanno,' says that he was one of the colonists of Smyrna who came from Colophon, and whose ancestors at a still earlier period came from the Nelean Pylos. To the reduction of Smyrna to Halyattes, he ascribes the melancholy character of his poems. (*History of the Literature of Antient Greece*, p. 115.) From Horace and Propertius we gather that his poems had reference for the most part to those appetites which are, in poetical language, expressed by the name of love. His mind however was of a melancholy turn, which gave to his writings a pensive cast not traceable in the writings of others who belonged to the same school. In the few fragments which we have remaining of Minnermus, he complains of the briefness of human enjoyment, the shortness of the season of youth, and of the many miseries to which man is subject. Minnermus was the first who adapted the elegiac verse to those subjects which, from this adaptation, are now usually considered as proper to it; Callinus, its inventor, having used it as a vehicle for warlike strains. The fragments of Minnermus have been several times edited, in the collections of Stephens, Brunck, Gaisford, and Boissonade, to which may be added Bach's separate edition, published at Leipzig in 1826. They have been translated by Ch. von Stolberg, Herder, A. W. Schlegel, and others.

(Ulrici's *Geschichte der Hellenischen Dichtkunst*.)

MIMOSEÆ are a division of the Leguminous order of plants, whose flowers are regular, the stamens long, usually indefinite in number, and hypogynous, and the flowers valvate in aestivation. They are in many cases polygamous, and their leaves are always more or less compound. The principal genus of the division is the *Acacia*. [*ACACIA*.] *Mimosa* itself consists of a considerable number of species, many of which are remarkable for the irritability of their leaves, a curious property which has always rendered them objects of interest. [*SENSITIVE PLANTS*.] The species commonly cultivated for the exhibition of this phenomenon is the *Mimosa pudica*, a South American annual. Among the useful plants belonging to *Mimosæ*, and not included in the genus *Acacia*, are the *Inga sapida*, *dulcis*, *biglobosa*, and some others, whose pods contain a sweet nutritious *fecula*, which renders them fit for food; and several kinds of *Prosopis*, the astringency of whose pods and bark renders them valuable for tanning purposes. In general, in the northern hemisphere *Mimosæ* are confined to tropical countries, or to those which have a high summer heat; but in the southern hemisphere they extend beyond such limits, as in Van Diemen's Land, where *Acacias*, called *Wattles*, are the commonest wood.

MINANGKABOU. [*SUMATRA*.]

MINARET (from the Arabic *menarah*, a lantern), in

Turkish and Eastern architecture, a very slender and lofty turret, having one or more projecting balconies around it, that divide it externally into two or more stories. They are used in Mohammedan countries for the purpose of calling the people to prayers, and therefore serve the purpose of belfries. They are however generally more numerous than such purpose actually demands, there being one at each angle of the building, and sometimes a greater number, and hence they become highly characteristic features, as well on account of their frequency as their tall column-like shape, which causes them to contrast so picturesquely with the domes that crown the edifice, and together with which they serve to produce a pleasing and varied architectural outline. The resemblance to the column form is frequently greatly increased by the uppermost gallery being corbelled and ornamented for a short distance downwards, so as to assume the shape and mass of a capital, above which the structure is usually made to terminate in a small polygonal alcove, with open arches on its sides, and crowned by an ogive or bulbous dome.

MINAS GERAES. [*BRAZIL*.]

MINCIO. [*PO*.]

MINDANA'O. [*PHILIPPINE ISLANDS*.]

MINDEN, one of the three governments into which the Prussian province of Westphalia is divided, is composed of the antient principalities of Minden, Paderborn, and Corvey, of the county of Ravensburg, the bailiwick of Reckenberg, and the lordships of Rheda and Rittberg. Its area is about 2000 square miles, and the population 397,870. It is subdivided into 10 circles: there were formerly 13 circles, but some have been incorporated with others. The soil is of unequal quality. There are some barren spots, but the greater part is fertile in corn: hemp and flax also are generally cultivated, and supply materials for the manufacture of linen and thread, which, as in the rest of Westphalia, are the chief branches of industry. The pasturage is good, and cattle abound. Iron, lead, and salt are the most important mineral productions. The Weser is the principal river, and the trade on its banks is very considerable. That part of this government which formed the principality was formerly a bishopric, which was secularised at the peace of Westphalia, and assigned to the electorate of Brandenburg.

MINDEN, the capital of the government of the same name, is situated in 52° 18' N. lat. and 8° 53' E. long., in a very pleasant spot on the left bank of the Weser, partly in a plain, and partly on the declivity of a mountain-chain, in which, at the distance of about two miles from the town, there is an opening through which the Weser flows, forming the celebrated *Porta Westphalica*. Minden is one of the oldest towns in Germany. The streets are narrow and irregular; the houses are in general built of stone or brick, but old-fashioned. The *Domplatz* (the Close) is however a handsome square, planted with trees. The little river *Bastan* flows through the town, and falls into the Weser. Over the latter river there is a very old stone bridge, 600 feet long and 25 feet broad. The French, in their retreat in 1813, blew up two of the arches. Since 1815 Minden has been again converted into a fortress, and is now one of the strongest places in Germany. It has six gates. Among the public buildings are four Protestant and three Roman Catholic churches, the largest and handsomest of which is the cathedral. Besides the gymnasium and a seminary for schoolmasters, there are several public schools, a Lutheran convent, an orphan-house, a bible society, and other useful institutions. The manufactures are of woollen, linen, leather, tobacco, &c. Of late years the refining of sugar has been carried on to a great extent. The vinegar manufactories and beer breweries and brandy distilleries are considerable. In the vicinity there are oil and saw mills. As the seat of the administration, the various public offices and tribunals of the government and the circle, and carrying on a considerable trade on the Weser, exporting hemp, corn, brandy, timber, yarn, &c., Minden is on the whole a thriving town, and the population (now 8000) is increasing.

The history of Minden presents some interesting particulars. In the year 1026 the emperor Conrad II. held a diet here, in order to have his son Henry III. elected king of the Romans. The Reformation having been introduced in 1529, the town was placed under the ban of the empire in 1538, and taken by the emperor Charles V. in 1547. In 1626 it was taken by Tilly, and in 1634 by George duke of Lüneburg. In 1651 thirty-one persons were beheaded in the town for witchcraft, and afterwards burnt.

on which occasion a debate took place in the provincial assembly on the question 'whence they should get wood to burn the witches?' In 1757 it was occupied by the French, in 1758 by the Hanoverians, and again by the French under Marshal Broglie in 1759. The movements of Prince Ferdinand having caused the French under Castries to take up a position to the west of the town, near the neighbouring village of Todtenhausen, they were attacked by Prince Ferdinand, who had only 40,000 British and Hanoverian troops, on the 1st of August, 1759, and defeated, with the loss of 8000 men, of whom 3000 were made prisoners. 2

MI'NDORO. [PHILIPPINE ISLANDS.]

MINE, a system of subterranean works or excavations formed in or going down upon any mineral or metalliferous deposit, for the purpose of exploring its contents, and extracting such portions of them as may be of sufficient value. These excavations are arranged in such a manner as to facilitate the drainage and ventilation of the works, to render them easily accessible to the miners, and to economise the application of labour in the extraction of the metallic ores or other mineral produce. In addition to the underground works which constitute the mine, properly so called, the term usually comprehends also the ground at the surface, together with the numerous appendages which are required there, as steam-engines, water-wheels, and other machinery for drainage, the extraction of the ores and their mechanical preparation, with various buildings and erections. The various works which constitute a mine, and their construction and arrangement, are fully described in the article MINING.

Mines are usually worked by companies, who hold grants or leases of the property from the mineral proprietors, for a certain term of years, commonly twenty-one. The risk and responsibility of the undertaking entirely devolve upon the former party, by whom the capital is provided and the management conducted, the proprietor of the mineral receiving a stipulated portion of the gross returns of the mine as a consideration for the use and deterioration of his property. This proportion varies much according to circumstances. In the north of England, where the mines are comparatively shallow and cheaply worked, it is commonly an eighth or a tenth; but in Cornwall, where the mines are deep and expensive, it seldom exceeds a fifteenth, an eighteenth, or a twenty-fourth, and is sometimes as low as a thirty-second. Although this payment, which is denominated 'dues' or 'royalty,' from the circumstance of all minerals having originally been the property of the king, is of course a matter of right, and claimed as such whether the mine is profitable to the parties working it or not, it is frequently good as well as liberal policy to greatly reduce or even remit it for a time, during periods of temporary poverty or loss, as a company may thus be encouraged to make further trials, which in the end may occasion discoveries highly beneficial to both parties. Considered as property, mines are exceedingly varied and fluctuating, some making very large profits, others barely paying their expenses, while upon many there is a heavy loss. Of the capital required to open mines in this country, no general average can be given: in some cases not more than 4,000*l.* or 5,000*l.* have been expended; in others, the sum has amounted to 150,000*l.* In the older and best established undertakings, the number of shares is small, as 64, 100, or 128. In some recent companies it has been subdivided into several thousands; but most of these have been unsuccessful. Of the profit of mines no general estimate can be given. In some cases it little more than repays the capital expended; in others it amounts to two or three hundred thousand pounds after paying back this sum, while of course every intermediate gradation exists. The duration of mines is very uncertain: some few are now working which are known to have been opened centuries ago, but these have been abandoned time after time in consequence of poverty or difficulties arising from imperfect machinery, and re-opened as improvements in the art of mining afforded a further scope for enterprise. It may probably be stated that mines of the soft metals, as copper, tin, and lead, rarely continue in a uniformly productive state for more than fifteen or twenty years together, although the discovery of fresh deposits of ore may prolong their existence greatly beyond this period. Coal and iron mines, on the contrary, are more permanent in their produce, and may continue to be worked for an indefinite term of years.

Great Britain is pre-eminently a mining country. With the exception of quicksilver and the precious metals, it con-

tains every variety of mineral in great abundance, and has been estimated to produce annually a greater amount of mineral wealth than all the other countries of Europe together. Rich and extensive mines of copper and tin are worked in Cornwall and Devonshire; and in Wales and the north of England there are immensely productive lead-mines. There are rich mines of copper in Ireland, and lead-mines are worked both in that country and in Scotland. The most productive mines of coal and iron in the world are opened in South Wales, in Staffordshire, and in Scotland, while valuable coal-mines are worked in Lancashire, Cumberland, Yorkshire, Durham, Northumberland, and many parts of Scotland and Ireland. Beds of rock-salt are extensively worked in Cheshire, and large quantities of salt are obtained from brine-springs in Worcestershire. The depth which mines have attained in this country is very considerable, amounting in many cases to from 200 to 300 fathoms. The quantity of water drawn from them is far greater than in any other part of the world, and the machinery employed is of the most powerful and perfect description. The extent and produce of the English mines, the large capital employed in them, and the boldness, the skill, and ability with which their management is conducted, are the admiration of foreign engineers, who make frequent visits to this country to inspect them.

Mines are worked on a more or less extensive scale in every quarter of the globe, and almost in every country, but more especially in those in which igneous and metamorphic rocks are abundant. France and Belgium have numerous mines of coal and iron, and many in which copper, lead, zinc, and other metals are worked.

Spain is a rich mineral country, and even in its present distracted state the produce of its lead-mines, and more especially of its quicksilver-mines, is considerable. Germany has long been celebrated as a mining country, and there is scarcely a metal which is not now produced there. The mines of the Harz and of Saxony are well known from the skill with which they are wrought, and the quantity of silver which they produce, as well as copper, lead, and other metals. Austria has numerous mines, producing, together with other mineral substances, a large amount of gold, silver, and mercury. The mines of Russia are rich in iron and the precious metals, but sparingly productive of coal; those of Norway and Sweden produce copper and iron. Of the mineral produce of Asia and Africa little is known, but mines of coal are worked in India and in China. Tin is obtained in Banca, Borneo, and the Malayan peninsula, and gold-washings have long been carried on upon the coast of Africa. The continent of America, although abounding in metals and minerals, is most celebrated for its gold and silver mines; the former are chiefly situated in Brazil; the latter have been extensively worked in Peru and Mexico. The once celebrated quicksilver-mine of Guanaco-Velica is situated in the former country, and rich copper-mines are now worked in Chili and Cuba. There are many mines of coal, iron, lead, and other minerals, now working in the United States of North America, and although hitherto little worked, mineral produce is probably abundant throughout many parts of British North America, in which the principal mines now existing are those of coal in Nova Scotia. The greatest depth to which any mine has ever penetrated is nearly 500 fathoms, or 3000 feet, and this only in one instance, in the Tyrol. The Samson mine in the Harz is about 2300 feet deep, and the celebrated Valenciana mine in Mexico attained the depth of 1800 feet, which is about the depth of the Consolidated Mines in Cornwall.

MINE'LLIUS, JOHN, was born about 1625, at Rotterdam, and died in 1683. He was rector of the public school in his native town, and edited many of the Latin classics, with short notes for the use of schools. He also published a translation of Terence in Dutch, Rotterdam, 1663.

MINERAL VEINS. [VEINS, MINERAL.]

MINERAL WATERS. [WATER.]

MINERALOGY, according to the definition given by Kirwan, is the art of distinguishing mineral substances from each other; and it is further observed by Mr. Brooke (*Encyclopædia Metrop.*, Mineralogy), that it may be regarded both as a science and an art: as a science, in reference to the knowledge requisite for supplying accurate descriptions of minerals, and forming what may be termed a *natural* classification; and an art, in reference to the arrangement of the descriptive characters for the purpose of afterwards distinguishing minerals from each other.

Mineralogy then must be considered as including the chemical composition of bodies, and an account of their external or physical properties. Both are requisite, for substances occur which agree in their chemical composition, and exhibit differences in their external characters; while there are other bodies which differ in their chemical constitution, but agree in their external properties.

Various methods of arrangement of minerals have been proposed by different authors, which we shall not minutely describe or discuss, as the alphabetical arrangement which has been adopted in this work precluding any other here. We may however observe that, according to Werner, minerals were divided into the four classes of earthy minerals, saline minerals, inflammables, and metals: Karsten classed them under the heads of earths, salts, combustibles, and metals: Haüy divided minerals into acidiferous earthy substances, earthy substances, non-metallic combustible bodies, metallic bodies, substances not sufficiently known to admit of classification, rocks, and volcanic products. In Phillips's 'Elements of Mineralogy,' the classes are earthy minerals, alkaline-earth minerals, acids, acidiferous earthy minerals, acidiferous alkaline minerals, native metals, metalliferous minerals, and combustible minerals. Berzelius has attempted a strictly chemical classification of minerals: he has however candidly admitted that considerable difficulties attend this method, owing, in part at least, to the uncertainty which exists as to what are the essential and what the accidental constituents of a mineral. The arrangement of Berzelius has however, with some slight modifications, been adopted by Mr. Brooke in the work to which we have already alluded.

We have already observed that mineralogy includes a knowledge of the chemical composition and of the external and physical properties of minerals, and they are all divisible into two great classes of crystallized and uncrystallized. With respect to regularly crystallized minerals we refer for an account of their forms to what is stated under CRYSTALLOGRAPHY. There are some substances which do not assume regular forms, but have an *imperfect crystalline structure*; while those bodies which are not either crystallized or crystalline, unless they are pulverulent, are described as *massive*, and these are subdivided into such as possess *particular forms*, as botryoidal, mammellated, nodular, stalactitic, reniform, globular, and *amorphous*, or *without any particular form*.

The *structure* of bodies is also an important character in some cases, and it may be compact, granular, fibrous, foliated, earthy, scaly, or laminar, and it is applicable both to crystallized and massive minerals.

Fracture is a very distinguishing characteristic in many cases; the principal are the conchoidal fracture, earthy, uneven, coarse, fine-grained, splintery, hackly, and irregular.

Hardness.—In this respect minerals differ greatly. [HARDNESS.]

Specific Gravity.—In this respect also minerals are very different from each other: for the modes of ascertaining it, see SPECIFIC GRAVITY.

Colour.—Minerals occur not only of every colour, but of every mixture of colours, and also colourless. Colour can scarcely be admitted as a very distinctive character, for there are some minerals which exhibit all colours: of this quartz is an example; for it is met with colourless, black, grey, brown, red, yellow, green, blue, purple, slightly bluish, pale grey, and slightly greyish.

Colour of Streak.—Sometimes resembles that of the mineral itself, but is often extremely different, so that it is impossible to foretell what it is likely to be. Hence the importance of the character. Sometimes the streak is merely shining, and its colour does not differ from that of the mineral.

Transparency, &c.—Minerals exhibit every degree of transparency, from the most perfect to absolute opacity. The different degrees are expressed by transparent, semi-transparent, translucent, translucent on the edges, opaque: it is also to be observed that some transparent bodies are doubly refractive, as calcareous spar, &c.

Lustre.—Minerals are described as having vitreous lustre (which is that possessed by the greater number of them), resinous lustre, metallic lustre, adamantine lustre, pearly lustre, resinoso-metallic lustre, vitreo-resinous lustre. When perfectly devoid of lustre, the mineral is described as dull.

Phosphorescence is the property which some minerals

possess of becoming luminous when heated: this is particularly the case with apatite and fluor spar.

Electricity.—There are certain minerals which become electric either by friction or by heat: this is the case with the tourmaline, diamond, &c.

Magnetism.—There are certain oxides of iron, some of which are natural magnets or loadstones, and others which obey the magnet. No minerals but oxides of iron, or such as contain this metal or the oxide, possess either the power of attracting as a magnet, or of being attracted by the magnet.

Besides the above more general and distinctive characters, the elasticity and flexibility of minerals are sometimes described; thus mica is flexible and elastic, while talc is flexible but not elastic. The touch, smell, taste, and adhesion of minerals to the tongue, are in some (but comparatively few) cases mentioned by mineralogists.

Without submitting the mineral to a regular analysis, advantage is often taken of the effects of heat by means of the blowpipe, with or without the aid of certain fluxes, as soda, phosphoric salt, &c.; and the mineral is stated to be either fusible alone, or with the assistance of the different fluxes, and the nature of the resulting compound is described; sometimes it is a colourless glass, at other times coloured, transparent, or opaque, &c.

MINE'RVA, or MENE'RVA, an antient Italian divinity, known to the Greeks as Pallas Athene. [ATHENE.] Her attributes corresponded in most respects to those of the Grecian goddess. She was the patroness of arts and industry, such as spinning, weaving, &c., and was the goddess of all the mental powers. Her statue was usually placed in schools; and the pupils were accustomed every year to present their masters with a present called *Minervul*. (Varro, *De Re Rust.*, iii. 2; compare Tertull., *De Idol.*, c. 10.) Minerva also presided over olive grounds (Varro, *De Re Rust.*, i. 1); and goats were not sacrificed to her, according to Varro, because that animal was considered to do peculiar injury to the olive (*De Re Rust.*, i. 2).

There was an annual festival of Minerva celebrated in Rome in the month of March, which was called *Quinquatrus*, because it lasted five days. (Varro, *De Ling. Lat.*, v. 3; Ovid, *Fast.*, iii. 809; Gell., ii. 21.) On the first day sacrifices were offered to the goddess, and on the other four there were gladiatorial combats, &c. There was also another festival of Minerva celebrated in June, which was called *Quinquatrus Minores*. (Ovid, *Fast.*, vi. 651.) There were several temples in Rome sacred to Minerva. Ovid mentions one on the Cælian Hill, in which she was worshipped under the name of Minerva Capta, but the origin of the name is unknown. (*Fast.*, iii. 835-839.) It also appears from several inscriptions, in which she is called Minerva Medica, that this goddess was thought to preside over the healing art.

The etymology of the name of Minerva is doubtful. The first part probably contains the same root min, men, or man, that we have in the Latin me-min-i, men-s, &c., the Greek μιν-ος, μιν-ος, &c., and the Sanskrit man-us. Cicero (*De Nat. Deor.*, iii. 24) gives a very curious etymology, 'Minerva, quia minuit aut quia minatur;' but some of the antient grammarians appear to have been nearer the truth in considering it a shortened form of *Meminerva*, since she was the goddess of memory. Festus connects it with the verb *monere*. Müller (*Etr.*, ii., p. 48) supposes that the word is of Etrurian or Sabine origin.

MINES, MILITARY, are excavations made in the rampart of a fortress, or underground, in order to contain gunpowder, which, being exploded, the rampart may be breached, or any works of the enemy, above or near the mine, may be destroyed.

The term *offensive* is applied to the mines which are formed by the besiegers of a fortified place; those which are formed by the garrison are called *defensive mines*, or countermines. The cavity in which the powder is deposited is called the chamber; and the approach to the latter is called the gallery. [GALLERY.]

Two kinds of mines were antiently employed in the attack of fortresses. One of them was merely a subterranean passage carried under the walls from the exterior ground; and being suddenly opened within the town, the assailants were enabled to enter the latter by surprise. The other kind was executed in a similar manner, and was intended to lay the rampart of the place in ruins; for this purpose, the gallery, having been driven as far as the walls, was carried on to the right and left under the latter, which were supported by

props of timber till the time appointed for the assault was come; then, the props being drawn away or consumed by fire, a portion of the rampart fell into the ditch; and the troops, who were kept in readiness, passed over the ruins into the town. Mines of this kind are described in a relation of the siege of the castle of Boves near Amiens, at which siege Philip Augustus attended in person. At the siege of Melun, which was carried on by Henry V., king of England, and the duke of Burgundy, in the year 1420, the besiegers having driven their mine almost up to the walls, and the besieged having executed a mine in opposition, a barrier was erected where the two galleries met, and there the king and duke fought with lances against two Dauphinois.

As the parties engaged two abreast, it is evident that the galleries must have been much broader than such are made at present. The old French writers occasionally applied the term mines to what were also then, and are now, called trenches. Thus, at the siege of Harfleur, in 1449, mention is made of broad and deep trenches by which the approach to the wall is said to have been rendered secure; and the same works are immediately afterwards called mines.

Gunpowder was, in 1487, used in military mining by the Genoese at the siege of Serezanella, a town belonging to the Florentines; but on this occasion without success. It is stated however, in the life of Gonsalvo de Cordova, that Peter of Navarre, a Spanish engineer, formed mines with gunpowder at the siege of Cephalonia, near the end of the fifteenth century, when the Venetians and Spaniards took the island from the Turks. And in 1503 the same engineer, or, according to Vallière, an Italian called Francis George, succeeded in taking by such a mine the Castle del' Ovo at Naples. This fortress was situated on a rock nearly surrounded by the sea, and had during three years resisted the united arms of the Spaniards and Neapolitans. From that time the practice of forming mines with gunpowder has been almost constantly followed in the attack and defence of fortresses. By means of 1173 mines, great and small, the Venetians defended Candia during more than two years (1666 to 1669) against the whole power of the Turks: by mines also, in 1762, the town of Schweidnitz was defended during 63 days by the Austrians against the Prussians. In the course of this last siege two of the mines fired by the besiegers had charges of powder amounting to 5000 pounds each; and the depth of the charges below the surface of the ground was from 18 to 20 feet.

In the siege of any place the mining operations of the besiegers are directed to the discovery and destruction of the galleries of countermines; to the blowing up of any advanced works belonging to the garrison; to the demolition of the wall of the counterscarp, in order that the descent into the ditches may be facilitated; and occasionally, to the formation of breaches in the principal ramparts. On the other hand, the countermines are employed by the defenders to destroy the trenches and batteries of the besiegers beyond the foot of and upon the glacis; and also the lodgments which may be made on the breaches or within the works. It is easy to perceive therefore, that a system of countermines must add greatly to the strength of a place, by obliging the besieger to proceed with circumspection in his approaches aboveground, in order to avoid the risk of being blown up at every step; and, according to Bousmard ('Essai général de Fortification'), if the glacis of a fortress be countermined, the duration of the siege, which otherwise would have extended to one month only, may be prolonged to six weeks.
